To prevent plague and to save Calcutta from commercial and domestic ruin, we would recommend the following course:—

1. Find out as a fact if plague does exist.

(a) Let a committee of qualified official and non-official physicians meet in consultation on a given case of suspected plague, and let them decide as to the true nature of the affection, after careful examination of the patient and after due discussion of the signs and symptoms of the disease.

(b) Let two competent bacteriologists residing in Calcutta—say, Surgeon-Colonel G. BOMFORD, M.D., Chief Physician to the Medical College Hospital, and Surgeon-Major EVANS, M.D., Professor of Pathology of the Medical College—declare their opinions on the microscopic appearances of the blood of such patient, and decide whether any of the three forms of bacillus of plague is present in his blood.

(c) Confirm by experimentation the decision of these two excellent pathologists, by reproducing *plague* in a few dogs or rabbits inoculated with the patient's blood.

(d) Call in MONSIEUR HAPKINS, and one of the following officers:—Surgeon-Colonel EDWARD LAWRIE, Surgeon-Major RONALD ROSE, Surgeon-Major PATRICK HEIN, or some other official specialist in microscopy and bacteriology, to express an independent opinion on the "germ" aspect of this question. If after such competent opinion it be decided that we have plague in Calcutta, it will then be time to adopt active measures to eradicate or to prevent plague.

2. AT ONCE, whether there be plague in the city or not adopt the following measures:—

(a) Get another Health Officer to temporarily replace Dr. COOK, since he has now ceased to perform the duties of Health Officer, and has apparently—judged by the daily reports in the newspapers—become special plague inoculator.

(b) Clean up Calcutta.

(c) Adopt measures to open up crowded areas, destroy unhealthy bustees, open up a few large straight wide streets, running from east to west and north to south of the town.

3. Restore confidence, peace and happiness, to the inhabitants of the city, chiefly the native population, by adopting such governmental measures for the prevention of disease as are best calculated not to outrage the social and religious customs and feelings of our Indian fellow-subjects. Such measures were fully detailed in the suggestions made by the Council of the Indian Medical Association in its representation to the Bengal Government in 1896, during the last plague scare.

By adopting all the above means we may save the commercial and domestic prosperity and happiness of Calcutta from inevitable ruin.

DILATATION OF THE STOMACH.

DR. INGLIS in the *N. Y. Medical Record* calls attention to the exaggerated importance attached to this condition.

BOUCHARD in his "Auto-Intoxication" states that "dyspepsia is accompanied by dilatation of the stomach in seven-eighths of the cases;" and again he says: "In a ward in a hospital out of ten patients taken at random, you will find three with dilatation." Once more: "Dilatation of the stomach may exist without inducing anomalous sensations, without dyspeptic or gastralgic symptoms, in two-thirds of the cases. It is a disease which does not announce itself; we know that it passes unperceived."

Put into concentrated form, these statements mean that of all dyspeptic patients seven-eighths have dilatation of the stomach, but that this very considerable number by no means represents the total; on the contrary, for every dilated stomach which causes dyspepsia, there are two others which do not. And finally, about one-third of our hospital patients of all sorts have dilated stomachs.

BOUCHARD represents the extreme of a class of enthusiasts who are looking for dilated stomachs and finding them, and who when they find them honestly believe that the first thing to do is to cure that dilatation. To this and there are multitudes of people who are having their stomachs washed out day after day for weeks and months.

According to DR. INGLIS the common sense view of the case is as follows:—

"The stomach is subject to all sorts of variations in size in perfectly healthy people. Its muscular walls may at one time keep well contracted when it is empty, or at another time they may relax. We may form an excellent idea of the varying conditions at different times in the same individual, by recalling the contracted or relaxed scrotum. The scrotum which is habitually exceedingly lax, still retains the power of firm contraction; as a rule, so does the stomach.

"Dilatation of the stomach can be easily produced. Leaving altogether to one side those cases in which pyloric obstruction,

however produced, is the efficient cause, let us note that the gases liberated by fermentation of undigested food cause but a slight pressure; they form much as the bubbles in yeast, yet, gentle as is the internal pressure, the walls of the stomach easily yield. It is only when a sufficient nervous impulse starts a contraction that we so much as become conscious that the stomach is full of gas.

"The dilatation of the stomach is mainly a matter of lack of nervous stimulus to set up peristalsis. Now we see why, while very frequent in the sick, it is relatively uncommon in the healthy. The sick, in the usual course of things, have a lowered nervous tone; they have dilated stomachs for precisely the same reason that they are constipated, and the latter disorder is probably quite as dangerous as the former."

WHAT IS HAFKIN'S PLAGUE SERUM?

We have read Dr. HARVEY's *Note* and have endeavoured to find an answer to the above question. What is HAFKIN'S Plague Serum? How is it prepared? Who knows anything about it besides HAFKIN? Let Dr. HARVEY reply:—

"In his anti-plague inoculation HAFKIN uses the bacilli of plague to confer a bactericidal power which shall enable the individual to resist the same in its natural form; but goes a step further and by injecting the toxins secreted by the bacilli in the cultivating medium in which they grow, he strives to produce an anti-toxic effect in the tissues which shall enable the patient to throw off the poison if it should gain access to his system, and so reduce the case mortality.

The serum takes some six weeks to prepare and the technique of the process requires great care and can only be carried out by experts, but the actual inoculations can be done by any medical officer according to printed instructions."

This is all we know about it, and this is about as much as the general public and the medical profession know about HOLLOWAY'S Pills, Mother SMITH'S Syrup, CLARKE'S Blood Mixture or BRECHAM'S Pills. They, like "HAFKIN'S SERUM" are secret remedies. We find the official profession of India blindly accepting bottles of stuff called HAFKIN'S SERUM as a plague-cure, and using it with as much credulity and probably less justification, as the gullible layman uses CLARKE'S Blood Mixture as a panacea for all bodily blemishes, and truly the spectacle is too ludicrous. We honestly believe that time and experience, if they prove anything, will prove that HAFKIN'S SERUM is a huge bauble that will burst as ridiculously as did the tuberculin cure of consumption by Professor KOCH.

ARE CIVIL ASSISTANT SURGEONS STILL GAZETTED OFFICERS?

At the fourteenth meeting of the Council of the Indian Medical Association held on Thursday, 17th March 1898, the Secretary read an important letter from certain Civil Assistant Surgeons complaining of a new grievance that had been inflicted upon them by the recent orders of the N.W. P. and Oudh Government, the practical effect of which is to deprive Civil Assistant Surgeons of their status as gazetted officers.

Resolved that application be instantly made to Government for a copy of the orders referred to, and that the serious consideration of the Council be given to the subject at the earliest possible date.

OFFICE OF THE INDIAN MEDICAL ASSOCIATION,
150, Dharamtala Street, Calcutta, 2nd April 1898.

TO THE SECRETARY TO THE GOVERNMENT,

North West Provinces and Oudh.

SIR,—Would you be so good as to allow me to have a copy

of the recent orders of your Government in regard to the Civil Assistant Surgeons of your Provinces which deprive them of the position of gazetted officers.

I have &c.,

(Ed.) JAMES R. WALLACE, M.D., F.R.C.S.

Secretary, Indian Medical Association.

1480
No. _____ of 1898
11-530 A.

FROM THE UNDER-SECRETARY TO GOVERNMENT,
N.W. Provinces and Oudh.
TO THE SECRETARY, INDIAN MEDICAL ASSOCIATION.

Dated Naini Tal, 4th May 1898.

SIR,—In reply to your letter dated 22nd April 1898, I am directed to say that no such order as referred to by you in regard to Civil Assistant Surgeons of these Provinces has been issued by this Government.

I have the honor to be,

Sir,

Your most obedient Servant.

(Ed.) H. W. WRIGHT,

Under-Secretary to Government, N.W. P. and Oudh.

UNQUALIFIED ASSISTANTS: PROPOSED MEMORIAL TO THE GENERAL MEDICAL COUNCIL.

SAYS the *British Medical Journal*:—It is proposed to petition the General Medical Council to authorise the examining bodies to hold, if they please, one or more special examinations during the present year only for the benefit of unqualified assistants over 40 years of age who have completed the medical curriculum and are of satisfactory moral character.

The promoters of this movement hold the opinion that by so doing the Council will remove a grievance and mitigate the severity of the new rule, which, while wise and necessary, presses with some harshness upon a very helpless class of men. It is thought that many of these, if unable to get upon the *Medical Register*, will be driven into the ranks of those unqualified and unregistered practitioners whose existence in such numbers is already a grave public scandal and a serious injury to the profession and should be a subject of deep concern to the Council. If the Council take this step, there are grounds for believing that such examinations would be held by some at least of the examining bodies.

Gentlemen who may wish to help by taking charge of copies of the petition for signature are requested to communicate with Dr. G. P. HADLEY, Wadham House, Loselle, Birmingham, who is willing to act as secretary to the movement.

PLAGUE PREVENTION MEASURES FOR CALCUTTA.

THE CHAIRMAN'S NOTICE.

THE following notice is published over the signature of Mr. R. T. GREER, C.S., Acting Chairman of the Calcutta Corporation:—

1. Quarantine will not be enforced by Government against Calcutta.
2. No segregation will be enforced if the entire household has been inoculated.
3. No one will be declared plague-stricken without being seen by a competent medical officer, male or female, deputed by the Municipality.
4. No one will be separated from his or her family. If necessary, all will go together to a camp, where the *qudahi* will be respected.

5. Compensation will be paid on the spot if any property is destroyed in being detached.

6. Encouragement will be given to the public to provide private family hospitals for the treatment of their relatives in their private homes, where proper accommodation is obtainable.

7. No person will be removed except on the order of a medical officer. The police are not authorized to examine or remove any one.

HISTORY OF THE CLINICAL THERMOMETER.

A LETTER from Dr. EDWARD F. WELLS, of Chicago, contains certain interesting details regarding the history of the clinical thermometer. He writes as follows:—"Dr. DONALD MACLEMAN, in his very readable 'Personal Reminiscences of SYME,' says of the year 1839 that 'the clinical thermometer had not then been invented.' In 1745—46 CLEGHORN encountered, in Minorca, an epidemic of pneumonia and published his observations upon the same in a volume entitled 'Epidemic Diseases of Minorca, London, 1782. On page 261 of this work, in describing the symptoms of the disease, he says: 'The internal heat was in several very moderate; in some less than natural; but for the most part it was so intense as to raise the thermometer to the 102nd degree, and often in the afternoon to the 104th.' The history of the clinical thermometer, since the idea of using it in measuring the temperature of the body in disease first occurred to SAMCTORIUS in the earliest years of the seventeenth century, is enveloped in considerable obscurity, yet it is certain that, with the published observations of DORNE (*Arch. Gen. de Med.*, 1837), ZIMMERMANN (*Prager Vierteljahrschrift*, 1852), and others, it is not historically correct to say that the clinical thermometer had not been invented in 1839, however true it may have been that it was not in common use."

CAPACITY OF THE STOMACH IN INFANTS.

A COMPREHENSIVE study of this subject in Escherich's pediatric clinic results in the statements: 1. That the stomach of maternally fed infants is smaller than in the artificially fed. 2. That the true capacity of healthy stomachs is less than that of the functionally or anatomically morbid. 3. That the elasticity is greater in small stomachs, and 4 that the true capacity of the stomach is a function depending upon the size of the pylorus. With a narrow pylorus the capacity is large and vice versa. The practical importance of the research lies in the facts established that every healthy infantile stomach can by passive increase in the internal pressure, or from lavages, attain a capacity and retain it for some time, which stimulates dilatation. Large capacity after a lavage does not indicate either atony or ectasia. Repeatedly produced artificial gastroparesis injures the functions of even a healthy stomach musculature, much more where there is motor insufficiency. Consequently loading the infantile stomach should be solidly avoided, and systematic lavages completely rejected, especially where there are gastroparetic or dilated conditions. The maximal single amount that should be allowed a normally developed infant is: First month, 90 c. cm.; second, 100; third, 110; fourth, 125; fifth, 140; sixth, 160; seventh, 180; eighth, 200; ninth, 225; tenth, 250; eleventh, 275; twelfth, 290.

A DOCTOR WITH A CONSCIENCE.

THE *Philadelphia Medical Journal* says:—"A good true story is told of a San Francisco woman and a doctor with a conscience. The doctor performed a successful operation for a rich woman, and when asked for his bill, presented one for \$50. The lady smiled and said, 'Do you consider that a

reasonable charge considering my circumstances?' The doctor replied: 'That is my charge for that operation; your circumstances have nothing to do with it.' The lady drew a check for \$500, and presented it to him. He handed it back, saying: 'I cannot accept this. My charge for that operation is \$50.' 'Very well,' she lady replied. 'Keep the check and put the balance to my credit.' Some months after, she received a lengthy demand bill, upon which were entered charges for treatment of various kinds rendered to all sorts of odds and ends of humanity, male and female, black and white, who had been attended at her expense. She was so delighted at it that she immediately placed another cheque for \$500 to her credit on the same terms, and it is now being earned in the same way."

OLIVE OIL IN HEPATIC COLIC.

BARTH reports the successful result of the administration of large amounts of olive oil in two cases of hepatic colic with icterus, caused by incarcerated gallstones. In one case 300 grams were taken every other day, and in the other 150 grams each day, the taste improved by a few drops of essence of anise. Part of the oil was found in the feces in a saponified condition, in the shape of small green particles which were at first erroneously supposed to be fragments of the gallstones. The rest was split into stearic acid and glycerin. The oil, besides lubricating the mucous surfaces and thus facilitating the expulsion of the stones, excites powerfully the secretion of bile, which flushes the biliary passages and removes particles that might ultimately develop into stones. On account of the increased secretion of bile, oil affects the system injuriously in adhesive cholecystitis, and it is also useless in dilatation and ascending suppurating infection of the biliary passages, and even injuries, on account of the impaired digestion and extra work forced on the liver.

CALCUTTA PLAGUE STATISTICS.

According to the official report there have been, since the 16th April up to the present date, fifty-three suspected cases with forty-three deaths. Quoting our friend the Hon'ble Dr. MAHENDRA LAL SINGH, M.D., C.I.E.:—"It does not appear from the official statement of Mr. BISLEY, the Secretary to the Government of Bengal, that in all the cases there were glandular swellings. No information is given as to how long each patient was suffering before he came under observation, and under what circumstances he got or caught the fever." Against this statement we have the views of CHEVRES, FAYENS, EWART, D. B. SMITH, CROMBIE and others, who declare most emphatically that a malignant type of septic fever, often accompanied by glandular swellings, is at certain times of the year endemic in Calcutta, and that such cases are to be found in fifth saturated *bustees* occupied by the very poorest classes of natives.

MINOR POINTS IN GYNCOLOGIC TECHNIQUE.

AFTER vaginal hysterectomy BURN applies tampons in three layers; aseptic, aniline dyed strings are fastened to each tampon, a different color for each layer, so that one layer can be removed and replaced at variable times without disturbing those that should remain undisturbed for longer periods. This trifling innovation, he states, has rendered him inestimable service during the last year. He also uses a cone-shaped cake of soap in making the toilet of the vagina, which does not slip out of the hand like the ordinary cake and get lost in the depths. RAVENHART's further improvement consists of a tube passing through the cone-shaped cake of soap, which fits into and closes the orifice of the vagina,

while the water passes through and distends the walls. We note on present the increasing tendency evidenced at the last French Congress of Surgery to prefer the abdominal route for hysterectomy.

THE SO-CALLED "DIPLOMA" TO MIDWIVES FROM THE OBSTETRICAL SOCIETY OF LONDON.

For many years the Obstetrical Society of London took upon itself the authority of examining women who had undergone one year's training in midwifery and of granting them certificates, which in course of time were styled "diplomas" and the holders of such diplomas began to style themselves "Licentiates of the Obstetrical Society of London" (L. O. S.). We had one such instance in Calcutta which was recently brought to public notice in the *Record*. Now it ought to be very generally known that through the vigorous action of the Lancashire and Cheshire Branch of the British Medical Association, the General Medical Council of Great Britain prohibited the Obstetrical Society from granting any further certificates or diplomas, and the holders of such documents were warned not to infringe the Medical Acts by styling themselves "Licentiates." Let us hope that medical men in India will prevent midwifery nurses from misusing their certificates by styling them "diplomas" or "licences."

DANGERS OF THE DAIRY.

DR. BRUSH in the *Medical News*, says:—One of the dirtiest habits which exist in many dairies is that of wetting a cow's teats to lubricate them, to make the milking process easier to the milker. This custom, not rare unfortunately, is the most common nasty habit permitted in many dairies. If it were not for the good that is sure to follow the agitation of these matters, I should hesitate to record that I have myself seen milkers spit upon their hands to wet the teats before they began milking, and then, when there was a certain quantity of milk in the pail, dip their dirty hands into it, and keep the teats dripping wet during the whole process of milking. Cow's teats should not be wetted in any manner, especially in winter, even to wash off dirt if it is already there. This should be removed with a brush or a dry towel. Wetting of the teats very often leads to chapping, and chapping to cracks, and these cracks often become running sores from the constant irrigation of the milking process.

BILIOUS HÆMATURIC FEVER.

DR. CORMOUX who has had an opportunity of studying these fevers in the French Soudan, arrives at the following conclusions (*Archives de Med. Navale et Coloniale* 1897, No. 5).

(1). Bilious hæmaturic fever appears to be chiefly the result of malaria. As is proved by the presence of LÄVERAN'S hæmatozoon in the blood.

(2). The theory which holds that it is an affection distinct from malaria is only hypothetical.

(3). Bilious hæmaturic fever cannot be confounded with yellow fever, remittent bilious fever, acute yellow atrophy of the liver, paroxysmal hæmoglobinuria, and certainly not with hæmoglobinuria due to quinine.

(4). In the Soudan this disease assumes a more severe type than in the other colonies.

(5). The ordinary drugs have hardly any effect—so far quinine is the only drug that any reliance can be placed in.

PLAGUE IN BOMBAY.

THE plague is abating slowly but surely. Our last year's experience fixed the period of decline at about twelve or thirteen weeks, and that experience promises to be repeated

this year. The following table shows the plague mortality and the total mortality since the decline began:—

	Plague Mortality.	Total Mortality.
Week ending 22nd March.....	1,250	2,368
" 29th ".....	978	1,998
" 5th April.....	679	1,510
" 12th ".....	563	1,308
" 19th ".....	541	1,202

The total mortality now exceeds the five years' average by 542, a number closely corresponding with the present recorded plague mortality.

MEETING OF THE COUNCIL OF THE INDIAN MEDICAL ASSOCIATION.

AN important meeting of the Council of the Indian Medical Association was held on Friday, the 18th May, at which the following items of interest were considered:—"The position of Civil Assistant Surgeons as gazetted officers, the reply of the Government regarding the grievances of Military Assistant Surgeon and Military Hospital Assistants, a representation to Government regarding medical education, medical examinations and medical diplomas in India, a representation to the Bengal Government in regard to the plague question in Calcutta, and some other minor matters. A full report of the proceedings of the Council will be published in our next issue.

DOES THE L. S. A. ENTITLE ITS HOLDER TO STYLE HIMSELF PHYSICIAN AND SURGEON.

Mrs. H. K. HUNTER, M.D., of Philadelphia, U. S. A., and L. S. A. London, began practice in London, and on his cards and sign board, styled himself M.D., L. S. A. (Physician and Surgeon). The British Medical Council prosecuted him on the 6th April for falsely using the titles, physician and surgeon, and the court held that the possession of M.D. Philadelphia, did not entitle Mr. HUNTER to style himself "physician and surgeon," nor did the L. S. A. London, entitle him to do so, and he was accordingly fined £5 for falsely using the title of "physician." It is announced that the Society of Apothecaries of London will defend their diploma and appeal against the decision.

THE PROSTITUTE DIAGNOSED BY HER PREHENSILE FOOT.

SAYS the *New York Medical Journal*:—"In the March number of the *Monatsschrift für praktische Dermatologie* there is a brief abstract of a study of the morphology of prostitutes, by JULLIEN, presented at the Geneva Congress of Criminal Anthropology. The author had examined fifty young prostitutes with reference to the presence of the *pes prænensis* of Italian observers. In this malformation there is an abnormally wide space between the great toe and its neighbour. In two thirds of the girls examined by the author the average distance between the two toes was more than an inch, and the deformity was commoner on the left side than on the right."

AN OVER-SENSITIVE LADY DOCTOR.

MISS ELGUEFF, at one time an extern of the Paris hospitals, and who afterwards received the degree of Doctor of Medicine at Moscow, has recently died at the age of 26 in the following distressful circumstances. She had been appointed Physician to the Asylum for Poor Children at Nijni-Novgorod. Recently a prematurely born child admitted to that institution died, and its death was attributed to burns caused by the hot flannels in which it was wrapped to keep it warm. Believing the child's death to be due to her own carelessness, Miss ELGUEFF put an end to her life. The *post-mortem* examination showed that the child had died, not in consequence of the burns, but from malnutrition.

SHORT NOTES.

The aforementioned probations for the Indian Medical Service are appointed Surgeon-Lieutenants from 26th January:—T. K. Lalany, Bengal; A. W. F. Ratt, Bengal; S. R. Douglas, Punjab; S. J. O'Meara, Punjab; G. Tata, Punjab; R. F. Datta, Punjab; A. T. Ganga, Punjab; G. O. Laing, Bombay; G. McPherson, Bombay; S. Buet, Bombay; A. G. Sergeant, Bombay; W. H. Cox, Bombay; De Vere Condon, Bombay; E. A. J. Gidney, Bombay; E. Kirkpatrick, Madras; F. D. S. Payrer, Madras; P. K. Chitale, Madras; and W. Lethbridge, Madras.

Lord Lansdowne announced at a banquet given by the medical profession on the 4th May in the Mansion House that it had been decided to organise a separate medical corps to be named the Royal Army Medical Corps, within which members will bear the same titles up to that of Colonel as other officers of the Army. The highest grade in the new corps will be called Surgeon-General.

There is now in Colombo Dr. Simond, of the Pasteur Institute, who arrived per M. M. steamer *Nelbourne* from Saigon. He is Director of the Pasteur Institute of Saigon and is leaving Ceylon for Bombay per S. S. *Chusan*. Dr. Simond has been sent by the French Government to continue his studies on the treatment of plague by serum at the Pasteur Institute.

The Court of Appeals has acquitted Dr. LaPorte, who was recently convicted in Paris by the Court of First Instance of having caused the death of a patient by performing craniotomy. In addition, the Advocate-General has withdrawn all accusations against him. Dr. LaPorte is earning his living as a shorthand reporter.

Surgeon-Captain F. G. Crawford has been appointed to act as Superintendent, Government Maternity Hospital, Madras, *vice* Brigade-Surgeon-Lieutenant-Colonel A. M. Branfoot, whose services have been placed at the disposal of the Government of India, Military Department, for employment as Principal Medical Officer, Bangalore District.

Mrs. McOloghry, wife of the Civil Surgeon of Karachi, met with a very nasty accident whilst being driven down Riphinstone Street in her victoria. The horse took fright and became quite unmanageable, and at last upset and smashed the trap. Mrs. McOloghry was violently thrown out but miraculously escaped any severe injury.

The Government of India has decided that a medical officer officiating in an administrative medical appointment should receive the full consolidated salary of the appointment if available, provided that no other officer is concurrently holding a lien on the same post, and counting service on its account for additional pension.

His Holiness POPE LEO XIII is reported to have said:—"Get only the best wine for your table; and free from care, soothe and refresh your heart with the grateful beverage, in the company of friends; but in all sobriety trusting not overmuch to it as a restorative."

We are informed that it is not Mr. William Tufner's intention to resign the Chair of Anatomy in Edinburgh University, and that the rumour that he would take this step in consequence of his election to the Presidency of the General Medical Council is unfounded.

Dr. C. Ranks, Superintendent of Emigration, and Surgeon-Captain Vaughan, Deputy Sanitary Commissioner, have been appointed by His Honor the Lieutenant-Governor to be Assistant Health Officers, Calcutta, in addition to their own duties.

A public entertainment was given yesterday at the Native General Library, in Poona city, to Surgeon-Captain Lloyd Jones, prior to his departure to Matheran. The entertainment was organised chiefly by members of the Hindu Plague Committee.

Surgeon-Captain D. M. Moir, Second Resident Surgeon, Presidency General Hospital, Calcutta, on return from military duty, is appointed to act as First Resident Surgeon of that institution.

Surgeon-Captain H. W. Pilgrim is appointed to act as Civil Surgeon of the 24-Perganas during the absence on leave of Surgeon-Major A. W. D. Leahy, or until further orders.

Surgeon-Major A. H. Burlton, Army Medical Staff, in medical charge, Station Hospital, Dum-Dum, is appointed to have charge of the civil medical duties at that station in addition to his own duties.

Surgeon-Captain C. R. M. Green, on return from military duty, is appointed to act as Superintendent of the Campbell Medical School and Hospital, Secidabad, during the absence, on leave, of Surgeon-Major J. B. Gibbons.

A bill requiring applicants for a marriage-license to appear before a medical board and forbidding the issue of a license to those afflicted with dipsomania, kleptomania, insanity, or tuberculosis, has been passed by the Ohio Senate, U. S. A.

A special additional pension of £100 per annum has been conferred on Brigade-Surgeon Lieutenant-Colonel Sir A. S. Lethbridge, an Anglo-Indian.

Leave of absence for seven months is granted to Major Alexander John Maunsel MacLoughlin, of the Burma Valley Light Horse.

Dr. JOHN P. MAYNARD, well known as the introducer of colloidion into the practice of surgery, died at Dedham, Mass., on 26th, February aged 72 years.

Surgeon-Colonel Maxham, P. M. O., South Africa, succeeds Surgeon-Major-General Walsh as P. M. O., Bengal Command.

VITAL STATISTICS OF CALCUTTA.

Statement of Deaths from Principal Diseases in Calcutta during the week ending 16th April to the 7th May 1898.

Week ending.	Cholera.	Small-pox.	Fever.	Bowel complaints.	Also other diseases.	Total.	Total population, according to the census of 1891.	Ratio per 1,000 of population per annum.
16th April	24	6	126	45	164	365	6,81,560	27.9
23rd April	42	2	145	45	175	409	...	31.2
30th April	38	8	161	50	208	454	...	34.7
7th May	16	7	131	59	164	377	...	28.8

ANTI-PLAGUE INOCULATION.

NOTE BY DR. HARVEY.

The following Note on anti-plague inoculation by Surgeon-Major-General B. HARVEY, Officiating Director-General of the Indian Medical Service, is published in the *Gazette of India* :—

From the earliest times the treatment of plague has been the opprobrium of the medical profession, and the results of recent experience seem to show that it is so still. The case mortality both in China in 1894-95 and in India in 1896-98 has ranged from 70 to 90 per cent., and it seems to be pretty generally admitted that such cases as recover do so in virtue of inherent power of resistance rather than as a consequence of medical skill, although isolated cases are, no doubt, helped to recovery by treatment.

It is only since 1894, however, that the true cause of plague has been demonstrated as due to a pathogenic microbe. This was discovered at Hongkong by KITASATO, and his observations have now been fully confirmed by other observers. Some such cause had for years been accepted by the profession as a matter of theory, founded on the analogous cases of small-pox, anthrax, and other so-called zymotic diseases and the results of bacteriological work had led to that belief that a remedy might be worked out on bacteriological lines similar to that found in vaccination against small-pox, and the preventive inoculations against anthrax, cholera, diphtheria, etc. No practical work could, however, be done until the theory had been proved to be a fact, and the general absence of plague in centres of scientific medical activity delayed the discovery until the outbreak in Hongkong in 1894. This speedily proved that the theories were right and gave a great impetus to the hope that a protective and curative treatment based on scientific principles might be worked out. This could only be done by experiment and by practice, and time was required to prove its efficacy. Numerous experiments have been made both in the laboratory and in plague-stricken districts, some of which have been failures, others more or less successful. Some have been intended as preventive, some as curative, some as both.

It must be remembered, however, that all these methods are tentative, that the experiments are only beginning, but the analogies mentioned above point to the fact that they are experiments in the right direction, and that we may hope for ultimate success.

The most promising results so far attained are those of M. HAFKIN, and it is to this method especially that this Note is intended to call attention. The idea is to combine a preventive and curative method which shall eliminate or greatly diminish the risk of contracting the disease, and at the same time reduce the case mortality. In his anti-cholera inoculations a bactericidal power is conferred on the individual by inoculation with attenuated common bacilli, so that when exposed to attack, his system can resist and kill off the invading microbe in its natural condition.

The result is diminished susceptibility and a consequent reduction of the absolute mortality; but when an inoculated individual does get the disease, the case mortality has so far been little affected.

In his anti-plague inoculation he uses the bacilli of plague to confer a bactericidal power which shall enable the individual to resist the same in its natural form; but goes a step further and by injecting the toxins secreted by the bacilli in the cultivating medium in which they grow, he strives to produce an anti-toxic effect in the tissues which shall enable the patient to throw off the poison if it should gain access to his system, and so reduce the case mortality. He frankly states that the process is based on hypothetical considerations, and that time and experiment alone can prove the validity of his conclusions.

It must be obvious that an experiment of this kind must be tried on a large scale before any trustworthy conclusions can be drawn, and that many difficulties and possible sources of fallacy will be met, and must be disposed of before we are entitled to say that events following inoculations are effects and not sequences.

Thus plague may disappear from a village immediately after inoculations have been done. It by no means follows that the inoculations have been the cause of the disappearance. The disease may have come to an end at this parti-

cular time and the inoculations be no more than a coincidence. Similarly the exemption of a jail or other inoculated community may have no connection with the inoculation, but be due to the fact that the plague bacillus has never been introduced, in which case there could have been no plague, though no inoculation had been done.

It is only when plague is actually present and when inoculated and uninoculated persons are living together under similar conditions in the midst of it, that we can begin to draw conclusions by comparing the incidence of the existing epidemic on the two classes; and it is only when a number of instances like the above have shown that under similar conditions similar results invariably appear, that we gradually substitute the relation of cause and effect for that of mere sequence; every additional instance strengthening the induction until we arrive at scientific proof.

The results so far arrived at go far to show that M. HAFKIN is working on the right lines; that he has already obtained a measure of success which would justify the voluntary adoption of his method by the public; that there is reason to hope that still better results may follow from further experiments and observation; and that in time it may be possible to expect as much from inoculation in the suppression of plague as we now do from vaccination in the stamping out of small-pox. At present, however, the process is too crude and imperfect to justify any compulsion on the part of Government, though it might well consider the advisability of holding out inducements to inoculation, by conferring certain exemptions from unpalatable restrictions on those who have submitted themselves to it.

Before discussing such questions, however, it will be well to briefly record the results already attained in different places where the inoculations have been tried.

At the Bombay House of Correction, plague broke out towards the end of January, 1897, and attacked nine prisoners, six of whom died. On the 30th January, inoculation was offered to the prisoners, a number of teachers and students of the Grant Medical College being done in their presence to encourage them. Six additional cases, three fatal, occurred the same day among the non-inoculated and three of the inoculated developed symptoms the same evening and also died. These cases are not included in the following figures, which show the results from the day after the inoculations till the epidemic ended eight days later :—

	No.	Cases.	Per cent.	Deaths.	Per cent.
Uninoculated ...	173	12	6.94	6	3.49
Inoculated ...	148	2	1.35	0	0.00

Mora in the Kolaba District, near Bombay, has a population of about 1,000; seven cases occurred among 429 inoculated persons. All recovered. During the same time there were 26 attacks among the uninoculated part of the population, 24 of which proved fatal.

Lower Damaon experienced a very severe visitation of plague in the cold season of 1896-97. The history of epidemic was very carefully investigated by Surgeon-Major LYONS, and the figures show that some 2,197 persons were inoculated, while 6,038 remained uninoculated. Between the end of March and the end of May 1897, no fewer than 1,482 of the uninoculated died of plague. The inoculated lost only 36, whereas had they suffered at the same rate as their uninoculated neighbours, they should have lost 332—a saving of close on 90 per cent.

At Lanauli in July 1897, M. HAFKIN and his assistants inoculated 323 persons in the two wadis most severely infected with plague; 377 others remaining uninoculated. Among these there were subsequently 78 cases and 58 deaths, while among the inoculated there were only 14 cases and seven deaths, instead of 67 and 49, as there should have been had they remained as susceptible as their uninoculated relatives, living besides them under identical conditions. Here the reduction in mortality was some 86 per cent.

Kirkee had a severe epidemic in the autumn of 1897, in which the followers belonging to the Royal Artillery suffered heavily, in spite of all possible precautions taken by the military authorities. These people numbered 1,580, living in about 40 barracks on the Kirkee maidan. "Out of the total of 1,580 individuals," to quote M. HAFKIN, "671 availed themselves of inoculation, while 850 belonging to the same families, living under the same roofs, having the same food, drink, etc., and subject to the same general pre-

ventive measures adopted by the military, remain un inoculated. From the time of inoculation up to the end of the epidemic the 850 un inoculated had 148 cases, with 98 deaths. Seeing the absolute similarity of the conditions, the 671 inoculated should have had, proportionately 112 cases with 77 deaths, if they had remained as susceptible to the disease as were their un inoculated brothers, sisters, parents, wives, husbands, children. Instead of that they had 53 cases, with 17 deaths. The number of 77 deaths was, therefore, reduced for them by 60, that is by 77.9 per cent.

These cases all occurred before the recent recrudescence of plague in Bombay. A large mass of additional information has since been accumulated, but has not yet been worked out; although it all appears to point in the same direction. The two following instances, however, are complete, and have been most carefully certified.

Umarski Jall, Bombay, was attacked by plague in January 1898. About half the inmates had previously been voluntarily inoculated, the numbers on the 1st January being—un inoculated 208, inoculated 198. A number of men were released during the month, others were inoculated, and on the 30th there were 106 un inoculated to 134 inoculated. Cases occurred throughout the month, ten in all, with six deaths, all in un inoculated prisoners. No inoculated person was attacked, and the disease was believed to have disappeared. Since then, however, there have been three suspicious cases among inoculated persons, one on the 10th February, one on the 28th, and one on 18th March. All these have recovered, and the hospital authorities at Parel were not quite sure that they were cases of plague. If they were, they were cases so much modified as to be with difficulty recognisable. I saw two of them, and they looked to me like mumps. Both parotids were equally affected (a rare thing in plague).

Undara, village about six miles from Baroda, was attacked by plague in January 1898. On the 5th February a careful census was taken, and showed a population of 1,029. Up to, and inclusive of the 14th February, only 79 plague deaths occurred, leaving 950 people to be dealt with. Of these, 513 were inoculated, leaving 437 un inoculated. As far as possible, an equal number of each sex, age, and family were done, and as all were living under precisely similar conditions as to a sanitary surrounding, food, drink, clothing, etc., the case is the best and most conclusive example yet available of the result of inoculation. Except for the inoculations all were on the same footing, and the disease had got a thorough hold of the place. The usual sanitary precautions as to segregation and disinfection were carried out, all plague cases being removed to hospital and every effort made to combat the disease in the usual way. The inoculations were done on the 12th, but the following figures are taken from the 15th, so as to eliminate cases in combating plague at the time of the inoculations. Three deaths occurred among the un inoculated between the 12th and the 14th inclusive, none among the inoculated. These three deaths, together with two others which might possibly have been due to disease other than plague, have been eliminated, so that no exaggeration as to the effects of the inoculation may be possible. The results up to the 2nd April are as follows, but no case occurred after the 26th March, so that we are probably dealing with a finished epidemic:—

Between the 15th February and the cessation of the disease plague cases occurred in 29 families, living together, as already said, under exactly similar conditions, save that some were, and others were not, inoculated. These 29 families comprised 185 individuals of all ages, 71 of whom had been inoculated and 114 not. The 71 inoculated had eight cases, with three deaths, while the 114 un inoculated had 28 cases, with 26 deaths. Had the inoculated been as susceptible as the un inoculated, they should have had 29 deaths, instead of three, and the inference seems irresistible that the inoculation saved 26 lives out of this small number or 89.65 per cent. Taking the whole numbers, inoculated, 513 had eight cases, or 1.56 per cent., and three deaths, or .58 per cent., while the 437 un inoculated had 28 cases, or 6.4 per cent., and 26 deaths or 5.9 per cent., just ten times as many.

The protective influence of the inoculations is brought still more strongly in some particular instances. Thus in hut 84, ward 4, five persons were inoculated in a family of ten. The five inoculated remained healthy, while two out of the five un inoculated got plague and died. In hut 18 of the same

ward three inoculated persons remained healthy, two un inoculated died out of a family of five. In hut 86 also in ward 4, one inoculated person escaped; two un inoculated died out of a family of three. In hut 8, ward 1, four inoculated persons escaped, while the one who remained un inoculated contracted the disease and died. In hut 24, ward 2, out of a family of two the inoculated member escaped, the un inoculated died. In hut 20, ward 3, one of three inoculated contracted plague, but recovered, while one of four un inoculated got it and died.

In two out of the three huts where fatal cases occurred among the inoculated a death also occurred among the un inoculated, and in only one instance in the whole village did a case occur among the inoculated, while the un inoculated went free. This was in hut 81, ward 4, where one of four inoculated contracted and died of plague, while two un inoculated escaped.

These figures have been verified* case by case and family by family, and seem to me to prove that, while inoculation, as at present practised is not an absolute protective either against seizure or death, it is of immense value both as a prophylactic and as modifying the severity of the disease and reducing the case mortality. This was 37.5 per cent among the inoculated, against 92.85 in the un inoculated.

Sulaiman Mussalmans at Baroda, a population of 404, living in an extremely dirty crowded locality, by the influence of their headmen and mullah, have had 833 inoculated, and no plague has occurred among them, although cases have been prevalent all round about them. They have been taken into camp in batches, while their houses have been cleaned, disinfected, and whitewashed. This case proves nothing, but, so far as it goes, is favorable to inoculation.

The Khoja community of Bombay has been largely inoculated, but the figures are not yet available. It is believed, however, that only some twenty cases of plague have occurred among several thousands inoculated, and that only three or perhaps four have been fatal.

Similarly out of some 600 inoculated dependents of His Highness the Aga Khan at Poona, all are believed to have escaped plague, though mixing freely with the general community among whom the disease was exceedingly severe.

The people at Undara are thoroughly convinced of the efficacy of inoculation and those of a neighbouring village (Jotal), where plague is now prevalent, sent in a deputation of their headmen to implore that they might be done. Arrangements were made to do as many as possible the following day.

It seems to me that these cases go very far to show the great value of the process. Plague at Daman and Undara have been carefully verified by independent observers, while some of the others have been already published and have not been challenged. How long the protection lasts can only be established by time, but were it only for a few months, we should have a valuable aid in saving people from attack during an existing epidemic. There is reason to believe, however, that it lasts much longer than this, for the large numbers inoculated during the first epidemic both in Bombay and Poona have, with very few exceptions, escaped the disease during the recrudescence.

The position, therefore, seems to warrant Government in extending facilities for inoculation and inducing the people to accept it by all legitimate means. The serum takes some six weeks to prepare and the *technique* of the process requires great care and can only be carried out by experts, but the actual inoculations can be done by any medical officer according to printed instructions. The operation is painless, but the serum causes a certain definite reaction in which the temperature rises to about 103° F and local irritation at the seat of infection usually lasts some days and is frequently severe. This makes people shy of undergoing inoculation unless they have something to gain by it, and the fear of plague is in many instances insurmountable to overcome these objections. Most people take an optimistic view of their chances of escaping plague—as YOUNG says, "All men think all men mortal, but themselves"—and, considering that the total mortality in both the Bombay outbreak has been little more than three per cent., the chances of an individual escaping are very large—thirty-two to one.

Current Medical Literature.

MEDICINE.

Extreme Hematemesis treated by Perchloride of Iron.

TWO interesting cases are submitted by Dr. GEORGE REID Esq., M.B.C.S.E. The first, a woman of 45, had for 9 months suffered from pain after eating, but had not been treated for it. She was at work when the hæmatemesis occurred with such violence that the floor and her clothes were soaked with blood, and there was beside her a small wash basin half full of blood, when medical aid arrived. She was pulseless, with pupils widely dilated and lips blanched, and apparently dead, but for the pulsations of the heart that could barely be detected. After partial revival under the usual treatment, she was placed on her back and given teaspoonful doses, every hour, of a mixture of pounded ice, glycerine and liquor ferri perchloridi. In 12 hours the quantity of ice and glycerine was increased but the iron was kept at 15 minims. The ice was then substituted by ice water and in two days she was taking 3i of the mixture every four hours but nothing else by mouth. She was kept absolutely still on her back and fed *a recto* for 15 days, after which she drank beef essence and milk. She made a perfect recovery and now (8 months after the attack) can do the hardest work and eat any kind of food without the slightest inconvenience. The second case, a delicate woman, of 38, was under treatment for gastric ulcer and hæmatemesis for a month during which she had three times vomited blood, and on the last occasion she was very collapsed and speechless with a very faint and rapid pulse and shallow breathing. She received the same treatment as the foregoing case, and making a slow but steady recovery, was five months later reported to be perfectly well and without the slightest pain after food.—*Brit. Med. Jour.*

Treatment of Epilepsy.

DR. PAUL FLECHSIG states that, by his bromide-opium method of treatment, in a series of fifty cases he has had six excellent results, with cessation of attacks for two and one four years. All the patients presented the following:—(1) long duration of the disease, some even twenty years; (2) other treatment, and particularly by bromides, has been without avail; (3) all kinds of psychical phenomena were present, such as weak memory, lack of nerve tone, irritability, morbid fear; (4) a "torpid" constitution, generally with anemia. As a rule, he does not begin with the combined opium and bromide treatment, except in those cases in which the disease has apparently developed through fear, sorrow, &c.; but starts with the ordinary bromide treatment. He uses the opium when bromides do not affect the disease, when bromidism begins, &c. The reasons for the good results of this treatment are as yet not positively known. The writer regards diet, rest in bed, rectal enemata, &c., as important accessories to the treatment. It may be that the opium produces its good effects in overcoming the nervous irritability and the senseless fear of these patients, for most epileptics are psychically perturbed. The patients must be treated as if quite ill, i.e., they must be under the continued observation of the physician and of a reliable nurse.—*Clin. Jour.*

Aphasia.

THE object of treatment is to restore the conduction of impulses along the usual paths or to open up new paths. In amnesic aphasia, endeavor to strengthen the defective recollection of words. Learn the words by heart,

and then adopt short reading-exercises. The exercises should be performed in front of a mirror, so as to enable one to recall the memory of the elementary movements. In motor aphasia other parts of the brain may take on function. Single sounds, then syllables, and then words, are taught. Along with the articulation exercises, writing-exercises with the left hand should be performed. Teach the patient to form words from printed letters. Sensory aphasia is far more difficult to teach. First attempts are made by means of written language. Develop lip reading, combining with it reading, writing, and other exercises. These cases are often complicated with a combination of different forms of aphasia. Much patience is required. Results so far encourage farther efforts.—*N. Y. Med. Rec.*

Treatment of Diabetes.

AS his investigations have convinced him that (1) the rigid exclusion of carbohydrates from the diet does not cause the disappearance of the sugar which is *always* present in the blood, and (2) that the increased albumen decomposition from a purely nitrogenous diet means loss of body weight by increased metabolism which diabetics are especially predisposed to; but which the injection of carbohydrates retards, MONSON says that as diabetes have by no means lost the power of burning sugar, they should be placed under no different conditions of diet than are granted a healthy person. If anything they must be allowed sugar; even more than in health, the form of carbohydrates, to overcome the loss of weight and muscular weakness that may eventually in death by asthenia as well as to prevent and retard the production or formation of various toxic bodies, and the severe and often fatal nervous and cerebral symptoms which they induce in the diabetic subject.—*Jour. Amer. Med. Assoc.*

Complications of Dysentery.

BEING an infectious disorder, dysentery may present complications analogous to those observed in various microbial pyrexias. As a contribution to the study of these complications, which are still imperfectly known, F. ZAGATO reports three interesting cases encountered by him during a severe epidemic of dysentery which raged in a small borough in the valley of the Po. The patients had suffered from severe attacks. Once on attempting to rise noticed that he could scarcely raise his right arm. Several days later the loss of power was complete and presented the form of a paralysis having all the characteristics of an infectious peripheral monoplegia. It disappeared a month after convalescence.

Both the other patients were seized by acute nephritis with excessive albuminuria and multiple cedema, the nephritis beginning, as in scarlatina, with the decline of the original disease. Cure took place under the influence of an appropriate régime.—*Le Bulletin Médical.*

Results by Flechsig's Opium-Bromide

Treatment of Epilepsy.

DR. KELLNER, who has over one hundred epileptics under his care at the Alsterdorf settlement tried Flechsig's treatment in twelve cases. These twelve patients took large doses of opium very well. In none of the cases was there any cure effected, but six cases were much improved.

There was hardly any gastric disturbance of importance to combat, and in all the twelve cases the opium treatment could be carried on for six weeks without interruption.—*Treatment.*

SYMPTOMS.

Death from Catheterisation.

At a recent meeting of the Vienna Medical Club, Dr. OTTO ZUCKERKANDL described a curious case of stricture of the urethra in which death occurred two hours after catheterisation. The patient, aged thirty-four years, had for two years been suffering from urinary troubles due to an annular stricture of the membranous part of the urethra. Dilatation was performed by Charrière's instrument, No. 15, and was within two weeks continued to No. 30 without any accident. The urinary troubles then disappeared and the patient remained well for a year. When Dr. ZUCKERKANDL saw him again he was well-nourished, but his skin and mucous membranes were pale, and the state of his urine showed the existence of purulent catarrh. A sound on being passed up to the stricture made its way out of the urethra and traversed the corpora cavernosa in various directions. After some ineffectual trials the stricture was at last passed by a No. 12 metallic sound, whereupon the patient was seized with nausea and rigors and died in collapse after four hours. Post-mortem examination showed in the bulbous part of the urethra an annular stricture permeable only by a slender sound; above and below this place the mucous membrane was marked with reticular scars, between which there were numerous apertures of false passages leading into the corpora cavernosa. There was also fatty degeneration of the heart-muscle. Death from catheterisation, said the speaker, is an extremely rare accident and may be preceded by urethral fever. French writers such as CLADO, HALLÉ and ALBARRAN have proved that urethral fever is an infective process originating in the urinary organs and, according to them, is due to bacterium coli. Dr. ZUCKERKANDL also made some reference to death after catheterisation without fever. There are cases where anuria due to reflex action follows catheterisation and proves fatal, and in hypertrophied prostate death may be the result of an attempt to introduce a sound. This is most likely to happen with patients who are suffering from incomplete retention of urine and whose distended bladder rises above the umbilicus. In these cases a trifling irritation of the genito-urinary tract—even the evacuation of the bladder—may aggravate latent disease of the kidney and rapidly bring about a fatal result.—*Lancet*.

Surgery of Chronic Peritonitis.

As the setting free of adhesion or the division of a band of organised lymph often immediately removes intolerable gastric or gastro-intestinal disturbances and chronic obstruction, LANGBEAU advocates abdominal section for chronic peritonitis of the peri (caecal, cystic, —gastric, —hepatic), pelvic and above all traumatic or postoperative types as well as in the septic or the dry form of tuberculous peritonitis; but care must be taken that the disease is not assuming a temporarily acute form when the abdomen is opened. As the diseased peritoneum is not always easy to distinguish and the intestines is often adherent, the abdominal wound should be small and the deeper tissues divided with great care; but the lower end of the incision should be brought low down in the female subject since it is important to explore the internal genital organs which are often the primary seat of the whole mischief. The cecum and appendix must be searched and tuberculous disease of the omentum or ulcerated areas in the small or large intestine looked for. The main part of the operation is thorough drying of the exposed cavity, DEQUAIN'S pouch and all diseased peritoneum, lying under coils of intestine, with fine sponges or compresses. It is very important to check the abdominal wound carefully. Wiping out with chemical solutions or flushings of the peritoneum are super-

fuous—often harmful—and drainage is compulsory only when the intestine is ulcerated.—*Prague Medical*.

A form of Neuralgia occurring in Cyclists.

W. H. BROWN, F.R.C.S.I., says:—Cyclists cannot be too particular as to the kind of saddle, as he had several cases where an ill-fitting saddle exerted an injurious pressure upon the nerves of the perineum. The lady patients complained of excruciating pain at the anus and the skin round about, so much so that in one case in particular defecation caused great distress, though there were neither piles nor fissures to account for such suffering. Among the male patients he noted scrotal and testicular pain with hyperæsthesia of the skin or the scrotum and of the inner sides of both thighs; retention of urine; extravasation of blood beneath the skin of the perineum, and one case complained that after two hours ordinary riding his penis became so insensitive that he could pinch the skin hard and feel no pain while the glands had lost its normal sensations. This anaesthesia, which passed off in three or four hours after his ride, returned as soon as he mounted his bike. The treatment under which all of them recovered consisted in rest for rider and bike and local sedative to the affected area.—*Brit. Med. Jour.*

Minute Anatomy of Intussusception.

POWER contributes a most interesting report upon the minute anatomy of intussusception based upon an examination of thirty-one specimens. Some of these were very old, but were so well preserved as to be excellently suited for microscopic examination. One of these, taken from the cecum of a child, is of especial interest, as it was shown by JOHN HUNTER to a medical society in the year 1789.

From the examination of these specimens it is clear that any part of the intestinal wall may be affected though the stress of the infection falls most often upon the submucous tissue and upon the circular layer of muscle. The mucous membrane may also be seriously injured. The amount of extravasated blood as well as its seat varies greatly. The extravasation is followed by inflammatory changes, in which the submucous tissue and the circular layer of muscle are chiefly involved. These changes terminate in hyperplasia of the connective tissue, leading to sclerosis; in a tryptic digestion, leading to the disappearance of every element in the wall of the bowel, and the conversion of its connective tissue into reticulum, or in diffuse suppuration and sloughing of the inflamed bowel, which is then separated and cast off by the ordinary process of ulceration.—*Med. & Surg. Rep.*

Sterilisation of the Skin in the Area of Operation.

LANDREER and KRAMER of Stuttgart record their experience of the capacities of formalin as a germicide to be applied to the skin of the patient. After the usual cleansing with soap and water, and shaving with the razor, a compress soaked in 1 per cent. solution of formalin is applied, and covered with a sheet of mackintosh. Immediately before the operation, the washing and shaving are repeated; the skin is then rubbed with ether, and finally with corrosive sublimate. Careful bacteriological examination showed the skin to be sterile in 80-90 per cent. of the cases. The wounds in sixty cases healed by first intention, except in three cases of large hernia, in which portions of the thick and were thrown off without any rise of temperature. The special merit of formalin as a disinfectant for the skin, lies in its capacity for acting in the form of vapour as well as of solution; it is thus able to penetrate the deeper layers of the skin, and to act upon the organisms therein embedded. The usual antiseptic, when applied to the skin, are only able to account for the bacteria on the free surface.—*Med. Mod. Jour.*

OBSTETRICS AND GYNECOLOGY.

Crossbirths and Caesarean Section.

THE CAT-HOEDENAKER read notes before a Dutch medical society in June, 1897 on seven successful Caesarean sections. Two were performed for neglected crossbirth cases. MENDES DE LEON objected to abdominal operations for such cases. THE CAT-HOEDENAKER and other experienced surgeons could doubtless save a majority of their patients, but the obstetrician and practitioner would be unfavorably influenced by his advice, as they might probably save just as many neglected crossbirths by purely obstetrical manoeuvres. THE CAT-HOEDENAKER alleged that there was great danger of rupture of the uterus in these cases, and the risk was actually increased if the obstetrician or practitioner attempted embryotomy. On the other hand, STRATZ and KOUWER had performed these obstetric operations without ever causing rupture of the uterus. Professor TREUB, the President, said that he agreed with the opposition, and considered that the meeting should express condemnation of Caesarean section in neglected crossbirths.—*Brit. Med. Jour.*

The Hand in Obstetrics.

THE hand as a dilating agent is the best obstetrical instrument at our disposal—better than BARNES' bags and the instruments which have come to us from the French school. As a result of extended experience, I am still able to say that in ninety-eight per cent. of all cases, the woman being within six weeks of full term and under surgical anaesthesia, any man can dilate the cervix with his hand sufficiently to enter the uterus and extract the child.

The use of the hand in obstetrics is of the utmost importance. For purposes of dilatation, examination and manipulation, the hand is the obstetrician's instrument.—*Canadian Prac.*

Length of Time a Lying-in Patient should Remain in Bed.

AN extensive series of tests at the Breslau Clinic is reported by BUTZER which establishes the fact that in certain cases discriminated by the physician, the patient can leave her bed on the second or third day, and that it is injurious rather than beneficial for normal women to stay in bed more than five days at most. Danger of lacerations is much more imminent from defecation or urination than simple moving around. Embolisms do not occur after the second day in normal women if we accept the published statistics. The patients who had quitted their bed early were much stronger when finally dismissed at the tenth day, than who had kept the reclining position longer.—*D. M. Week.*

Tympanites Uteri.

LINDENTHAL discussed, before the Vienna Royal Society of Physicians, the origin of tympanites uteri, as derived from a series of four cases he had investigated. From these he demonstrated the condition to be due to the influence of organisms. Though a variety of germs were found in the different cases, in all he found an anaerobic bacillus, which was capable of producing gas in large quantities in a short time. The bacillus seemed to correspond closely with the bacillus of malignant oedema. He also stated that, from the fact of the tympanites being present, although the fetus survived, the former supposition of its origin from foetal decomposition was untenable.—*Edis. Med. Jour.*

Phenomena attributed to Menstruation.

LAURENT does not entirely disbelieve in certain ideas, popular amongst women in different countries, relating to menstruation. In the sugar refineries in the North of

France the female hands are kept out of the premises when the sugar is being boiled, and also when it is undergoing the process of cooling. The objection to women is that if one or more were menstruating the sugar would be blackened. A similar notion prevails in Coshia (China) in respect to the preparation of opium. Another doctrine, also common to Europe and Asia, is that the hands of a menstruating woman break objects of strength and toughness. Especially is this notion entertained in relation to stringed instruments. A performer on the double bass at a theatre in Paris declared that if his wife touched one cord of the instrument during her "period" it snapped at once. Two young women, excellent violinists, informed LAURENT that they never played when menstruating, as the snapping of cords interfered greatly with the performance. One of these ladies admitted that she was extremely nervous and irritable at the period. Several much more credible phenomena have been reported, and clearly come under the head of neuroses. Young girls sometimes acquire an idea that their clothes stick to them at the period. Such a person gets nervous during the catamenia, and trying to pull off a tight glove falls, and then believes that it sticks to her. Since she thinks that the same must be the case with her clothes, she loses the power as well as the will to pull them off. LAURENT observed this in two sisters. Their body linen did not stick to the skin through perspiration or any visible cause, but it could not be taken off during a "period" till a servant pushed her hand between it and the skin.—*Brit. Med. Jour.*

Indications of Ourettage.

DR. LANCASTER in the *Victorian Medical Semi-monthly* sums up the indications for curetting the uterus as follows:

1. All those cases of persistent leucorrhoea, with tender and subinvolved uterus.
2. For dysmenorrhoea in young girls and maiden ladies who, in spite of internal remedies, must spend two or three days out of each month in bed, and in whom an undeveloped and oftentimes flexed uterus is found.
3. For barrenness, when the fault is plainly with the women, and no tangible cause other than poorly developed uterus exists for failure to conceive.
4. In all cases of menorrhagia, whether from fibroids, polypi, or other neoplasms, especially in the menorrhagia occurring at "the change of life," and which is not amenable to other treatment.
5. In all septic diseases of the uterus or its appendages, whether following accouchement, abortion, operations, or gonorrhoea, whether the inflammation be acute or chronic, curettage is indicated, and the earlier the better.—*Med. Times & Hosp. Gaz.*

Hæmorrhage at commencement of Pregnancy.

SEVERE flooding occurring 15 days after suppression of menses of a multipara in her fourth conception MIGNIERS stopped the flow by tampon; but as hæmorrhages recurred causing severe anemia, he advised the induction of abortion which she refused to submit to. So gestation was allowed to proceed, and later on when the foetal heart sounds were audible, a sero-sanguinolent discharge persisted. The woman had not reached full term when this paper was read. In another case, where there was twin pregnancy, the delivery of the second fetus was followed by the extraction of a great red mass (a very large thrombus) with much liquor amnii. The patient said she had been struck on the abdomen. Anæmia compelled TREUB (Lancet) to induce abortion in a patient who had uterus hepatized from one corner of which he removed a living fifth-month fetus and from the other an atreted ovum.—*New Arch. & Obstet. et de Gynec.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Contribution to our Knowledge of the Thyroid Gland.

THE hitherto views of (a) the thyroid being an organ so necessary to normal life that the products of metabolism occasioned by its loss poison the central nervous system, including metabolic disturbances (cachexia and tetany) that cause serious illness and death, and (b) the administration of thyroid extract (secretion) acts as an antitoxin to such products and prevents these symptoms by the iodothyron which is formed and stored in the gland are flatly contradicted by HERMANN MUNK whose experiments show—

(1). That while the thyroid gland is not absolutely necessary to life or health, its removal is seldom or never followed by ill effects, and those animals that survive the operation grow healthy and fat. Thyroidectomized cats conceived and bore healthy kittens.

(2). If kept in captivity after any serious operation, most animals refuse to eat, and this accounts for the cachexia. Some animals never show any symptoms at all, in others spasms and tetany arise at very varying periods after operation, and these attacks may never recur or may recur many weeks after, and may result in death, but there are no myxedematous symptoms and everything goes to prove that after thyroidectomy metabolic products do not poison the central nervous system so as to produce tetany and a special (myxedematous) cachexia.

(3). The giving or withholding of thyroid gland preparations makes no difference to the animals on whom thyroidectomy has been performed.

MUNK admits the removal of the thyroid endangers life, but contending that few of the experimenters, whose views he opposes, knew the clinical features of tetany in animals, he argues that if an animal remains in good health for weeks and months after the removal of the thyroid, that gland is certainly not an organ necessary for life, and one cannot therefore maintain that all animals necessarily die of tetany or cachexia after removal of the thyroid, if they fail to die of some intercurrent disorder, while there is no kind of evidence to show that thyroid substance has any antitoxic influence on the metabolisms supposed to be evoked by excision of the thyroid gland.—*Edin. Med Jour.*

Role of the Blood-Vessels and of the Parenchyma in Inflammation.

R. VIRCHOW claims that inflammation shows itself as an irritation, both of the blood-vessels and of the nerves, of the specific as well as of the non-specific parenchyma. He differentiates four kinds of inflammation, exudative, infiltrating, parenchymatous, and proliferating. The irritation is generally of a chemical, occasionally of a mechanical nature. Proliferation is only a peculiar form of cellular power, it always implies the formation of new material. The "new material" need not be taken directly from the vessels, since this form of inflammation (the proliferating) likewise occurs where there are no blood-vessels, in the latter case the cells take their material from their surroundings through their power of attraction. Nourishment consists in the assimilation of the taken-up material, the cells having the peculiar innate elective power of absorbing from the neighbouring tissues what is best suited to them at that time. Heat and redness do not occur in inflammation of non-vascular parts. Inflammatory redness is due to irritation of the nerves. The result of parenchymatous inflammation is fatty metamorphosis. This inflammatory fatty metamorphosis is to be distinguished from the non-inflam-

matory; the latter is due to a metabolic disturbance. The former always implies, as a condition preceding the fatty change, either cloudy swelling or cellular proliferation, both caused by the attractive power of the cells. In conclusion, VIRCHOW remarks that the fibrin in inflammation can very often be regarded as the product of parenchymatous metabolism.—*N. Y. Med Rec.*

Pathological Physiology of Thrombosis or Blood Coagulations.

COEVEL gives the results of a study of the changes he has observed in the process of clotting of the blood within the vessels during life. Organisation of the intravascular blood clot is made at the expense of the endothelial cells lining the lumen, both in veins and arteries, the fibrous network of the clot serving only as a scaffolding or support for their development. The phenomena of organisation are very rapid. On the first day there is a modification of the endothelial cells. Capillaries appear about the third or fourth day, and connective tissue about the ninth or tenth. Infection of the blood clot delays both the extent and rapidity of the process of organisation, though a certain degree of traumatism may favor them. The phenomena of organisation are everywhere the same, e.g. vessels, heart, lung, and ordinary connective tissue. It is always the living endothelium which starts the process, and it is most perfectly seen in the connective tissues.—*Edin. Med Jour.*

Microbes in Acute Rheumatism.

DR SINGER of Vienna has explained 92 cases of acute rheumatism, and in a great number of patients has ascertained the presence of staphylococci and streptococci. He has examined the blood, urine, synovial effusion, and various complications during life. In three necropsies he was twice able to find the same microbes that he found during life, in one of them the synovial effusion was sterile, though the walls of the synovial cavity contained bacteria, in the third case there were hemorrhages in the periarticular tissue, and in these hemorrhages he found groups of streptococci. SINGER considers that the necropsies explain why arthritic effusions in cases of acute rheumatism are found often to be free from microbes, in such cases the bacteria probably have their seat in the periarticular tissues only. SINGER believed that these microbes are the actual cause of acute rheumatism, which shows its pyæmic nature by its relations to erythema multiforme, sorethroat, etc. He therefore does not accept the view that the action of salicylates is actually specific.—*Brit. Klin. Week.*

The Gonococcus.

DR HENRY HEIMAN, of New York, who has been conducting an extended series of experiments with the bacilli of gonorrhæa, has summarized his work as follows—

1. The gonococcus can be kept alive in certain liquid culture media as long as eighty-two days.

2. The gonococcus can be transplanted probably indefinitely from one culture medium to another. I succeeded in transplanting it twenty-five times.

3. Fifteen cases of chronic urethritis, pronounced on clinical evidence cured, were found to be entirely free from gonococci when judged by cover-glass preparations and cultures.

4. The statements of STRAUSS, PASCHOWS and BRAUD that the gonococcus occurs in the normal urethra is not satisfactorily proven in their published experiment.

5. Rectal gonorrhæa can often be detected by suitable examination. In two out of four cases of my own, bacteriological diagnosis was possible.

6. Gonorrhæal arthritis may be a sequela of ophthalmia neonatorum.

7. My experiments on the inoculation of the eyes of newborn rabbits and kittens with gonococci gave negative results.—*Med. Age.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Bacteriology of Milk.

A YEAR or two ago, the public were startled by the report of myriads of bacteria in every drop of ice-cream, and were very near inaugurating a raid of extermination on the poor Italian itinerant vendors, when it was announced that the ice in the best West End and City cafes were even more prolific in bacteria than ice-cream. On the other hand, Sir W. ROBERTS showed long since that milk (as well as blood and urine) drawn direct from the body through sterilised tubes into sterilised flasks stopped with sterilised cotton-wool would, without boiling, remain unchanged for months or years. The fact is that all so-called "spontaneous" changes—curdling, souring, etc.—are the work of agents introduced from without, though, under the ordinary surroundings of industrial and social life, practically unavoidable. The actions of *B. coli*, *B. typhosus*, and other pathogenic or excremental organisms, have been carefully studied, to the neglect to some extent of those which are ubiquitous and non-pathogenic—a grave omission, since these may prove directly or indirectly no less dangerous to life. O. GUENTHER and H. THOMPSON show that the ordinary coagulation of milk is due to one species of bacillus absent from fresh drawn milk, but always present in large numbers a few hours later. It is $1 \times 4 \cdot 0 \cdot 5 \mu$, stationary, not sporiferous, colored by GRAM'S method, gives rise to lactic acid, grows best in saccharine solutions at 25°C , with or without access of air; it does not liquefy gelatine, gives off no gas, forms a dew-like film on the surface of agar, grows badly on potato, and not at all on wholly non-nitrogenous media.

A. LEUBERT describes a bacillus (*B. l. of FLUGGE*) which peptonises milk. It is short and thick, very mobile, and, in strong contrast to that above described, has no action on sugar or fat, but liquefies blood-serum and reduces albumin in twenty-four hours to about one-thirtieth by peptonisation. Such milk may be drunk by adults with impunity, but is dangerous to children. The poison does not seem to be in the casein and peptones formed but in the bodies of the bacilli themselves.

Streptococci and staphylococci may be found along with pus cells in the milk of cows suffering from "garget," mastitis, or mastitis, and abscesses in or near the gland. They are best detected by centrifugating the milk, drying some of the thickest deposit on a glass slide, washing out the supernatant fat with ether and staining. Much infantile diarrhoea is doubtless caused by such milk, and outbreaks of gastro-enteritis among adolescents or adults have been traced there-to.—*Prac.*

How to Prevent Typhoid Fever in Rural Districts.

BARNES says that the introduction of cisterns in rural districts will almost entirely eradicate typhoid fever. As an example he cites the experience in a town in Pennsylvania in which cistern water is used almost exclusively for drinking purposes because the limestone underlying the soil makes it impossible to obtain good well water. In this town, within the last five years, there have been only three cases of fever which were plainly typhoid, but even calling them so and reckoning one death for every twenty-six cases, would make the death-rate in this community from typhoid fever something like one per ten thousand. The unpleasant taste of cistern water is due to decomposing vegetable matter. This can be in a great measure avoided by having a "cut-off" by which the first water of the rainfall is turned into the street, and not into the cistern. Further improvement in the water can be readily obtained by dividing the cistern by a brick partition, filling one-half of this to a depth of three feet with a filter of coarse sand and broken stone. The water is allowed to run into the side which contains the filter. It then passes through the filter and through holes at the bottom of the partition into the other side of the cistern from which it is pumped out for use. In this manner pure water may be obtained at small expense, and the family using it will absolutely avoid the possibility of having typhoid fever.

Diet and Health.

For breakfast I have a large cup of tea, with milk or cream; brown bread from two to three ounces; and usually one and a half ounce of fish, or half that quantity, and that very rarely, of bacon. Sometimes for a few days I take a cup of coffee with half milk, but no fish or bacon. Lunch is a cup of cocoa or chocolate, if the weather be cold; if it is warm, a small tumbler of milk, about six ounces, with the same quantity of bread as at breakfast. At both meals I use butter, not a quarter of an ounce, and quite as much jelly or marmalade. This is my usual lunch, but occasionally instead of cocoa I have a baked apple, or some prunes with milk, or strawberries and cream so long as I can get them, or, very rarely, vegetable soup. When I have no milk I take usually a morsel (not half an ounce) of cheese. At 4 p.m., a small cup of tea, and sometimes biscuit or cake. For dinner, as seven, which is my chief meal, I have soup, from peas, lentils, potatoes, celery, carrots, etc., the first two made with no meat stock, and the others with a little from lamb or a bone; or fish soup, the only animal soup I indulge in. Fish, mostly white deep-sea fish, direct from Montrose. Of this I take no more than three ounces with a potato and always another vegetable fresh from the garden. If there is no fish, I may take once or twice a week an ounce or two, certainly not more, of lamb, game, rabbit, or tripe; but often I have neither fish nor flesh. The dinner ends with stewed fruit with cream, or pudding, or fruit tart; of these I take a fair helping. During the winter season instead of fruit or pudding, I often have celery, with cheese, oatmeal, and butter. On this diet I enjoy the best of health, and for my age (seventy-eight) am up to a fair amount of exercise, walking three to six miles daily in good and sometimes in bad weather, and usually part of this is up a steep road with a rise of 250 feet. The only confession I have to make is, that when at home, I do not rise till I have had breakfast and read the newspaper. This is a habit I have recommended to many approaching my own age, and those who have tried it admit that they are stronger for the rest of the day. I enjoy breakfast just as much as my other meals, though I never feel what can be called hunger, and have not done so for many years. I could omit a meal at any time without discomfort. This I have long looked upon as the best proof of perfect digestion. During very warm months I take rather less bread and butter, and I do not try to make this up by taking anything else.—GEO. KERR, in the *Practitioner*.

Medico-Legal Question of the Infection with Syphilis of the Nurse by the Nursing.

As either may have contracted the disease from the other or the attacks may be independent, and as in the event of an action being brought the question of priority of syphilis in nurse or child must be determined to enable a true verdict, Professor FOURNIER points out that in examining the child the first point to be proved is "whether the syphilis is acquired or congenital" and the absence or presence of chancre must be first ascertained and every case in which secondary symptoms occur within the first eight weeks of life is congenital not acquired because the secondary symptoms of aquired syphilis can not appear before 60 days since the incubation period of chancre is 30 days, to which add the second incubation period of an average 40 to 45 days. Again, the presence of lesions such as nasal and cranial deformities, coryza, pemphigus, maceramus, epiphyseal dislocations, &c., peculiar to congenital syphilis will decide the question.

In examining the nurse the genital organs must be carefully inspected and mucous patches and erosion distinguished from chancres and especial notice paid to the presence or not of babies. If a chancre be found in a position likely to convey contagion to the nursing, and its incubation and the existence of an indurated axillary tube noted, there is no need for further evidence, but should there be no sore, other relics of syphilis must be looked for and the previous condition of the nurse, her husband and her own child must be closely investigated. The condition of her own child is of the highest importance, as its immunity is almost absolute proof of the immunity of the mother. Syphilis may very rarely bear apparently healthy children, but this is scarcely probable when the mother has recent secondary syphilis present.—*Lancet*.

THERAPEUTICS AND PHARMACOLOGY.**Hyoscin and Hyoscyamin as Mydriatics.**

EMMERT is surprised at LANDOLT and GYGAX saying in their recent *Pocket-book of Therapeutics for Ophthalmic Surgeons*, that "hyoscin and hyoscyamin have been abandoned owing to their uncertain action." For the last sixteen years EMMERT has found hyoscin to be the most constant and reliable mydriatic we have, and this has been the experience of many others. As to the hydriobromate it is a very stable salt, and has been introduced into both the Swiss and German (under the name scopolamin, which is identical with hyoscin) pharmacopœias. Its advantages over atropine are: (1) It dilates the pupils more quickly; (2) the mydriasis does not last so long, and the paralysis of accommodation lasts about the same time, and this is an advantage for healthy eyes; (3) it cures inflammatory affections of the eye quite as quickly as atropine; (4) even if used for a long time it has no local irritant action (as "atropine conjunctivitis"); (5) it is five times more powerful; (6) used in solutions as strong as 1 in 500 or even 250, any general intoxication is very rare, and even if present, quickly passes off and is not dangerous; a solution of 1 in 1,000 is usually sufficient, and never causes poisoning; (7) intraocular tension is not influenced in chronic, though hyoscin is contra-indicated in acute, glaucoma; (8) instead of stimulating the cerebral cortex and quickening the pulse like atropine, it has a paralyzing action on the former and slows the pulse, and hence is much safer in heart disease. Considering the weaker solutions required, it is practically as cheap to use as atropine. As regards hyoscyamin, its little use as a mydriatic is not due to an uncertain action, but because it has no advantages over atropine.—*Brit. Med. Jour.*

Internal administration of Salol in Scleroderma.

THIS being a disease sometimes tending to spontaneous recovery, some reserve is necessary when speaking of the curative action of remedies in scleroderma of which rheumatism has also been regarded as an ætiological factor; but A. PHILIPPOEN claims to have obtained good results in scleroderma by the internal exhibition three to four times daily of 7 to 15 grain doses of salol. Massage and gymnastics are also indicated where muscular atrophy or contraction has set in.—*Treatment.*

Serum Treatment of Leprosy by the Carrasquilla Method.

BLOOD to the extent of 250 cc. (about 3vi) being drawn from a leper is allowed to stand for 12–25 hours, when the blood serum, drawn off under antiseptic precaution, is slowly filtered through two layers of wadding (between which is interposed a layer of camphor) into flasks and sterilised, 15 to 80 cc. of this serum are injected beneath the skin of a horse. The injection is twice repeated with 10 days' interval and 10 days after the last injection 1 to 3 litres (from 36 to 106 ounces) of blood are drawn from the horse, and its serum, separated as was the leper's blood. The leper to be operated on is first injected with 0.5 cc. of this horse serum the quantity of which is every third day raised by 1 cc. at a time till 20 cc. have been attained unless the reaction is too lively. CARRASQUILLA and MEDINA, who thus treated 100 lepers, claim amelioration in all and cure in some; but HALDREW was not so successful with his 9 cases and JEANSENHUT declares the serum is not pure enough to yield the results claimed for it, since leprosy also tends spontaneously.—*Treatment.*

Thymol in the treatment of the Fever of Tuberculous.

E. DE BENE finds that thymol is a valuable remedy in the treatment of this often obstinate and troublesome symptom. He finds it to be of distinctly greater value than quinine, antipyrin, acetanilid, and sodium salicylate, as unlike these the thymol has no depressing effect. It is administered in four-grain doses in the form of a powder enveloped in a wafer. These may be given three or four times a day, and gradually increased in frequency until sixty or seventy grains are given each day. He finds that tuberculous patients are very tolerant of large doses of thymol, and that it is well borne by the stomach, it seeming to favor digestion.—*Medicine.*

Atropin in Delirium Tremens.

THE remedies employed in delirium tremens are only relatively effective, but cold baths affect the syndrome favorably. Reasoning from the assumption that they stimulate the inhibited cerebral centers, TUWIK, of St. Petersburg, has been trying atropin, which also stimulates the centers, and announces that it is extremely successful. In ten out of eleven cases a single injection of one milligram of atropin threw the patient into a calm and deep sleep in fifteen to twenty minutes. In the one case in which delirium persisted it was complicated with erysipelas, and yielded finally to a cold bath. He recommends, therefore, subcutaneous injections of atropin, supplemented, if necessary, by cold baths in the treatment of delirium tremens.—*Semaine Med.*

Unna's Ichthyol Ointment for Profuse Sweating of the Feet.

Ichthyol	25 parts.
Water	15 "
Lanolin	25 "

M. Oint.—*Prac.*

Acne with Constipation.

"KASAGRA" (Stearns' Cascara Aromatic) in laxative doses preceded by a saline laxative. After the proper dose of the kasagra has been ascertained in each case, combine with it 1 to 3 drops of Fowler's solution three times a day. If the anemia is marked use hæmoferrum (Stearns') in conjunction with the above. If a scrofulous condition exists, employ Stearns' wine of cod liver oil. The usual topical applications of sulphur, hot water, green soap, etc., should not be neglected.

Take of kasagra (Stearns' cascara aromatic)	...	1 fl. oz.
Fluid Extract of Berberis Aquifolium	...	1 fl. oz.
Simple Elixir	...	2 fl. oz.

Mix. Sig.: Dose, teaspoonful after meals

Hepatic Stimulant.

"Kasagra"	1 fl. oz.
Fluid Extract Wahoo	4 fl. oz.
Fluid Extract Senna	4 fl. oz.
Fluid Extract Wild Cherry (soluble)	4 fl. oz.
Simple Syrup, q. s.	4 fl. oz.

Mix. Sig.: Dose, 1 to 2 teaspoonfuls.

A combination acting especially on the liver and of unusually pleasant and effective action. The wild cherry may often be well replaced by hydrocyanic acid in proper doses, thus giving the combination especial value in dyspepsia as manifested in vomiting and gastric distension with constipation.

Neurasthenia.

THE following formula is said to be useful in neurasthenia:—

Iron Lactate	3 drachms.
Iron Arsenate	8 grains.
Extract of Nux Vomica	7 "
Extract of Gentian	45 "

M. Divide into a hundred pills. Two to be taken with each meal.

Correspondence.

PLAGUE INOCULATION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In the 'Plague Notification,' there is one item—*inoculation*,—which is, in the opinion of the authorities and the Health Officer, a prophylactic of plague. Where are the statistics to prove that it is so? Like the anti-cholera inoculation of M. HAFKINE, which was proved by Dr SANDERSON to be a failure in the majority of cases, and which, we know, signally failed where it was tried, plague inoculation would share the same fate. None will like to introduce a poison into his system, unless he is fully assured, that it is a prophylactic and not attended with any immediate danger. Inoculation, it is evident, did not succeed in Bombay. Did it succeed anywhere? The test of the *vaccine virus* can alone be had in a place, where an epidemic is raging. Has M. HAFKINE tried his so-called specific in such a place, and with what result? Our Health Officer, who seems to have a well-balanced mind, ought only to give his verdict in favor of inoculation after extensive trials. Mere assertions of HAFKINE will not carry conviction to the minds of the people, unless they are corroborated by statistical facts. Educated people cannot encourage fads and faddists, but practical measures and practical men. Mr RISLEY is an advocate of inoculation, but has he made the experiment upon his own person, or on the person of any of the members of his family? If not, who is to show the way? Unless some Europeans and Indians of high position show the way, the people will not take to it. Preaching is one thing, practice is another. The unrest that was subsiding will only increase in its dimensions, if the source of inoculation be not thoroughly removed from the minds of the people, and there will be a general stampede of the citizens, both high and low. Why are the authorities over solicitous with regard to a so-called antidote which is even now a puzzle to the scientists? Government, we find, is going to import twenty-five medical officers from Bombay, but why we don't know. Would it not be more advisable to bring out from any part of Europe a sound bacteriologist? There is a cry in the town that the plague has come. We have some knowledge of this subject, and our opinion is that those cases, which have occurred are not real plague cases, but cases of remittent fever with glandular swelling, and they break out at certain season of the year. Plague breaks out generally in provinces and countries situated on the sea-coast and places which are adjacent to hills and mountains. In a disputable question, the opinion of other experts must be taken and full reliance should never be placed upon one expert, however high his scientific attainments and bacteriological knowledge be.

Yours &c., A. MEDICO.

3rd May 1898.

II.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With reference to a statement by H. H. the Lieutenant-Governor of Bengal, it seems to have been forgotten by His Honor, that since last year, the utmost endeavour has been made by the Municipality and a num-

ber of the people at Bombay. Not only were all inoculation stations kept open, but round from house to house and street to street, with regard to the cases of plague seen by Dr. SANDERSON in Calcutta in 1896, I have already expressed an opinion in my report on plague that Dr. SANDERSON was absolutely right, and justice was not done to him.

I have not the least doubt that plague has been occurring sporadically in Calcutta since 1896, or possibly even previous to that, and that possibly it is endemic in Bengal. In regard to the measures that are to be taken against plague in Calcutta, I may say that they are practically the same as the measures that were carried out in Bombay in 1896, except that inoculation may be used, as let us hope, on a larger scale.

Rule 17 of the instructions issued by me in September 1896 for the treatment of cases of plague was as follows:—

"Whenever the Medical Officer of a ward is satisfied that the isolation or proper treatment of a patient suffering from bubonic fever is not practicable in the house where the patient is, the Medical Officer is forthwith to call on the Ward Inspector to make arrangements for the removal of the patient to the hospital appointed for that purpose at Arthur Road."

The methods about to be used in Calcutta are practically the same as those that were used in Bombay by the Health Department in 1896. The idea that cases of plague will at once be followed by an epidemic, is a delusion, which may cause a confidence in measures that will not be fulfilled, and a loss of all faith in the right measures when the epidemic comes. The fall in the mortality, previous to the recognition of cases of plague, is an ominous sign often observed. In Karachi, the phenomenon may be studied. In the calamity gathering over Calcutta, let not the people think that there is any new method, except inoculation, about to be used, that will save them; for, if they do, they will be disappointed; and great as the hopes excited, deeper will be the despair afterwards. If in the warfare against this disease the pest was easily to have been destroyed, it would not have borne in all ages the terrible designation given to it.

Yours &c. T. S. WEIR,

Brigade-Surgeon Lieutenant-Colonel.
BOMBAY, 2nd May 1898.

THE ADVANTAGES OF HOME SEGREGATION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—At the present moment it might be of public service to enumerate the following advantages which are claimed for home segregation in a case of suspected plague:—

1. The infection remains confined to the locality where it has originated.
2. Quarantine of the infected house can be resorted to if necessary.
3. Voluntary isolation of the sick becomes the rule when there is no forcible removal.
4. Notification of the disease will come voluntarily from the people.

particular attention to the following points:

8. Prompt removal of contamination of infection by the people from houses as indicated hereby.

9. No secretion of any suspected plague cases.

10. Knowledge of plague hospitals and segregation camps are avoided, as they themselves become the foci of infection.

11. The infection cannot be transmitted to other healthy parts of the town by the ambulance service.

12. No falsification of the death reports.

13. No panic and therefore no chance of riot.

14. No abandonment or secretion of dead bodies of suspected plague cases.

15. Less strain upon the sanitary inspectors and medical staff.

16. Better chance of recovery of the sick when they have no dread of removal to hospitals.

17. Benefit to the patient when he can get his own medical man to attend him and his own relations to nurse him.

18. No inconvenience to the people for want of menial servants or bazaar supplies.

19. Trade is not paralysed.

20. A better chance of stamping out the disease when the co-operation and confidence of the people are secured.

Yours &c., RAKHAL DAS GHOSH, L.M.S.

CALCUTTA, 14th May 1898.

ANGLO-INDIANS IN THE I. M. S. OF MADRAS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—You ask for the names of Anglo-Indians who have risen in the service belonging to Madras, I give you a few names:—

Dr. Shortt, who had most of the letters of the alphabet behind his name and took so much interest in snake poison. He sucked a wound of a native who was snake bitten and suffered from symptoms of poisoning, and is supposed to be the first person to have done. He rose to be Surgeon-General and Inspector-General of Vaccination.

Dr. Keess, another Eurasian or Anglo-Indian, rose to be Surgeon-General. From being a student in the military branch of the Subordinate Service he became the Principal of the very College he was educated in. His son is an M.A., and Professor of the Agricultural College, Madras. Another is M.B.C.S., and L.R.C.P. Lond., and is a practitioner in Madras.

Dr. Wilkins, a retired Military Assistant Surgeon who went home and took his degrees and the much coveted F.R.C.S., Edin. He was for years Demonstrator of Anatomy in the Madras Medical College.

Surgeon-Lieutenant-Colonels O'Hara (two brothers I.M.S. Madras).

Dr. H. A. F. Noller. You will see by the Italic letters after his name in the Army List that he is a linguist having passed in Hindustani, Tamil, Persian, (high proficiency in all) and also in Russian. He is an excellent sample of a self-made man who worked his way

upward and passed from the ranks. He is without doubt a great credit to the Anglo-Indian community.

Surgeon Colonel T. H. Pope, another Anglo-Indian, partly educated in Madras and partly in Edinburgh, is the son of the Rev. Mr. Pope, the great Tamil Scholar, now Professor of one of the universities in England in Tamil. There are two other brothers of Dr. Pope, one in the Educational and the other in the Survey. All three are excellent men.

Surgeon-Majors BURTON, NEWLAND, and D'ACOSTA, Surgeon Captains PIRTO, STEWART, PEREIRA, VICKIN, and SUTHERLAND—are all Anglo-Indians. More names another time.

Yours &c., MADRAS,

(Bravo Madras! the Benighted Presidency has a noble record for the Anglo-Indian race. It only needs publication. Let's have the roll.—ED., I.M.R.)

—:O:—

PUBLIC ESTIMATE OF OUR EDITOR AND HIS PUBLIC WORK.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Though the annexed article taken from *The Critic* of the 18th April concerns yourself, I trust, for the benefit of your readers, you will not object to keep it out of the columns of the *Record*. An excellent portrait by Messrs. HARRINGTON and NORMAN of Calcutta was issued with this laudatory notice of our Editor:—

"DR. JAMES R. WALLACE, M.D., F.R.C.S."

"Only when genius is married to science" says HERBERT SPENCER, 'can the highest results be produced'—and when to these, allied in close communion, a will that triumphs over all obstacles, and an energy that never tires, such attributes must necessarily mean success to any undertaking with which the possessor is associated.

Dr. JAMES R. WALLACE, whose portrait the *Critic* presents to its readers to-day, is essentially a man of many parts and infinite capacity. As a medical man his name is a household word all over India, and in his recent visit to England he added fresh laurels to his fame by obtaining the much-coveted title of F.R.C.S. His contributions to the *Indian Medical Record*, of which he is Editor, mark him as a vigorous thinker abreast of all the medical questions of the day, while his pen is the pen of a ready writer, demonstrating the truth of VOLTAIRE's, BUTLER LYTTON's and W. KING's variously-translated axiom that "the pen is mightier than the sword." He has also been elected a Municipal Commissioner for the Town of Calcutta, a position which this paper feels confident he will adorn with ability and that enthusiastic energy which is one of his chiefest characteristics.

The recently-started Imperial Anglo-Indian Association which has risen like the phoenix out of the ashes of the Eurasian Association, and is already spreading its arms, octopus-like, all over the country, owes its inception principally to the energy and zeal with which Dr. WALLACE has advocated its interests, and so fanned the smouldering flame into a steady, vigorous blaze. In stating this, the *Critic* does not, even in the least degree, wish to detract from the earnest and able co-adjutors of the Doctor, but his recent visit to England, where he

needed a deputation to the Secretary of State to represent Anglo-Indian disabilities with a view to their removal, the time and attention he is giving to the Association, his contributions to various Indian subjects in its interests, all entitle him to special honorable mention, and this paper feels confident that his fellow-directors will join hands with the *Critic* in wishing Dr. WALLACE all the success his energy and ability so richly deserve.

Yours &c., J. M. PEREIRA, M.B., C.M. Edin.

—:0:—

HIGHLY PLACED ANGLO-INDIANS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—This my fourth list as follows, for which you will, I hope, gladly make room:—

1. F. E. Brewin, Examiner, Marine Accounts, Bombay.
2. J. A. Guider, Superintendent of Police, Poona.
3. J. H. Irvine, H. M. S. Miat, Bombay. (Died June 1897.)
4. J. S. Maidment, Assistant Superintendent of Stamps, Bombay
5. George Miles, Assistant Secretary to Government General Department, Bombay.
6. John Hampton, (Captain) Superintendent Punjab Government Flotilla, River Indus.
7. U B. Rix, Assistant Engineer, P. W. D Karachi Canals (Retired), now Managing Agent, Karachi Tramway Company.
8. William Swanseger, Assistant Auditor-General, Bombay. (Retired) Died at Pancharani, June 1897
9. William Turner, Assistant Secretary to Government, Railway Department Bombay (Retired)
10. J. D'Aroy (Captain), Conservator of Rivers. Punjab.
11. William Pearson, Assistant Secretary to Government, General Department, Bombay.
12. Samuel Abdiel White, Assistant (Uncovenanted) Commissioner in Sind
13. W. A. Blakeman, Chief Superintendent, Account-General's Office, Bombay.
14. W. Plankett, Deputy Collector, Poona
15. H. J. Miles, Deputy Sheriff, Bombay

Yours &c, W. H. T.

CHROMBIE TAMASHAS AND THE LIKE, PROHIBITED BY GOVERNMENT.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—As a proof that your views of things are generally very sound, I wish to refer to the fact that you referred in scathing terms to the demoralising effect of "sham shows" such as the recent CHROMBIE episode, and is it not remarkable that following close upon your condemnation there goes forth the following resolution calling attention to the ideas of the State as to unfitness and impropriety of the very "shams" you recently exposed. Here is an epitome from the *Gazette of India*:—

The Government of India in the Home Department draw attention to their Resolution of the 23rd July 1887, regarding the receipt of testimonials and addresses by Government servants:—By the rules attached to the resolution quoted, all servants of Government are prohibited, subject to the stated exceptions, from receiving complimentary or valetudinary addresses in any form or testimonial of any kind; and from attending public meeting or complimentary entertainments

of a formal public character held in their honor. Several instances have recently occurred in which arrangements for the presentation of testimonials have been made and subscriptions collected apparently in ignorance of the fact that the proceedings were irregular, and that the rules prohibit officials from receiving testimonials of any kind. It has also happened more than once lately that a formal character has been given to farewell entertainments, such as are permitted by Rule 8, by the publication in the newspapers of the speeches made at them. The Governor-General in these circumstances finds it necessary to call the attention of local Governments and Administrations to the rules, and to request that it may be again impressed on all officers that they must be strictly observed. With a view to bringing them to the notice of the public, the Governor-General directs that they be re-published in the *Gazette*. The rules do not apply to the receipt of addresses by the head of any Government or Administration.

Yours &c., MEDICUS.

—:0:—

OUR QUANDAM SUPERIORS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As I hear that the President of the Madras Municipality, to whom the services of a few Hospital Assistants have been lent by the Surgeon-General with the Government of Madras for Plague Duty, wishes that these medical officers should work under the orders of his Sanitary Inspectors, I request you and the numerous readers of your valuable journal to be good enough to inform me whether a Hospital Assistant, who gets a full training both practically and theoretically in almost all the branches of the Medical Science for about four years, can in any way be considered inferior or subordinate to a Sanitary Inspector who is instructed only in the elements of Hygiene for the short period of three months, just because the former draws a less pay?

I think that these Hospital Assistants ought to be under the immediate orders of Surgeon-Lieutenant J. W. CORNWALL, the Health Officer of the Municipality, (as per orders of the Surgeon-General to the Hospital Assistants, viz., "to report themselves to the Health Officer for orders") or at least under the supervision of his assistant, Mr M. K. MARREW, L.B.C.P. and S., who is entertained as a temporary measure on account of prevalence of plague in other presidencies, as these officers alone are capable of supervising their work and not the Sanitary Inspectors, the majority of whom are not even able to look after the conservancy staff of sweepers and toties, &c.

Yours &c., A. QUERIST.

MADRAS, 1st May 1898,

—:0:—

IS IT THE PLAGUE?

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following letter has appeared in the *Englishman*—"As a mofussil Civil Surgeon, I have read Mr. RISLEY's statement as to the plague in Calcutta with no little interest and anxiety and I think that more information should be given. The details of each case should be circulated that we may judge whether the clinical symptoms are those of plague. The mere finding of a bacillus is no proof of plague as we know from the 'plague scare' in October 1896. There is of course a 'plague' bacillus, but it is not so typical as we are led to believe.

The strongest proof is that of infection, and we may well refrain from hasty judgment when we learn that of those who were isolated with the supposed cases of plague none were attacked. How is it that with a Professor of Pathology at the Medical College and a Bacteriological Laboratory in the General Hospital compound, it becomes necessary to ask for M. HAPKINS's assistance? I do not wish to blow my own trumpet or that of my service, but if I could not find ten men in Bengal capable of doing such bacteriological work as is required in a properly furnished laboratory, I would resign the service.

Yours &c., CIVIL SURGEON."

THE SUN LIFE ASSURANCE COMPANY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you kindly let me know through your columns whether the "Sun Life Assurance Company of India, Limited" is a reliable one. In the policy, issued by it, the word *Limited* is omitted. They say as it is only a branch of the London Sun Life Assurance Company, Limited, and therefore the word limited is not used. It is under the management of GEORGE LUCAS KEMP, Esq., Calcutta. I don't see its advertisements in your esteemed journal.

Yours &c., A. OOMMAN, L.M.S.
Civil Apothecary.

PUNALUR, 28th April 1898

Book Reviews & Medical Trade Notices.

ESSENTIALS OF PHYSICAL DIAGNOSIS OF THE THORAX.

By ARTHUR M. CONWIN, A.M., M.D.

(Publishers: W. B. SAUNDERS, Philadelphia.)

THIS very handy synopsis is the Second Edition of a work published not long ago, under another title, and presents in systematic form the gist of the science of physical diagnosis as applied to the thorax. There is an additional section setting forth the signs found in each disease of the chest. The methods of physical diagnosis and the signs in the diseases of the several organs, as detailed in the book before us, should, and will, we feel sure, prove of great value and usefulness to practitioners and students.

MEDITERRANEAN, MALTA, OR UNDULANT FEVER.

By M. LOUIS HUGHES,

Surgeon-Captain, A. M. S.

(Publishers: Messrs. MACMILLAN & Co., Ltd., London.
Price 7s. 6d.)

THE subject treated in this work must necessarily be of great importance to Great Britain as well as to the French, Italian and other Mediterranean nations, being the result of the experience gained by the writer in the treatment of the fever mainly among the Military at Malta. He feels very strongly the need that exists for discovering and removing the cause of "this scourge of the Mediterranean." The work is illustrated with undulatory tables and a series of charts describing experiments on monkeys.

THE PATHOLOGY OF RELAPSING FEVER.

By L. J. PISANI, F.R.C.S., I. M. S.

(Publishers: Messrs. THACKER, SPINK & Co., Calcutta.)

THIS little book, dealing exclusively with the pathology and the methods which should be employed for the detection of the spirochæta of relapsing fever, should prove very useful to all medical men, for though the clinical

aspects of the disease are generally well described in ordinary text-books very little is mentioned of the pathological changes. It is a handy little volume which is very well got up and has three coloured illustrations.

EXERCISES IN PRACTICAL PHYSIOLOGY.

By AUGUSTUS D. WALLER, M.D., F.R.S.

(Publishers: Messrs. LONGMANS GREEN & Co.

Price 2s. 6d.)

THIS volume forms Part III of a series of exercises and demonstrations to accompany "An Introduction to Human Physiology," and deals with the Physiology of the Nervous System. It is intended to facilitate the class-work of the laboratory, and is meant for advanced students, by whom it cannot fail to be appreciated.

KOLAVIN; KOLA-STEARN'S KOLABON;

KOLAOLYL, KOLA CORDIAL

THESE compounds are prepared by Messrs. FREDERICK STEARN'S & Co. from fresh undried true African Kola, which, as is well known not only takes the place of food and drink, without impairing the digestive functions, but is also a powerful cerebro-spinal stimulant and therapeutic agent specially indicated in cardiac, pulmonary and renal affections and wherever a bracing tonic is required. It is also an antidote to the opium habit, and has the property of giving greater resistance to muscular fatigue, but does not make its patient its slave like Coca does.

CARBOLIC SMOKE BALL.

EVERYBODY knows the immense value of carbolic acid as a germicide and how difficult it is to handle this substance. Influenza is very troublesome also, but has been known to yield to carbolic smoke. With these facts in mind the British Druggists, Limited, of 86 Clerkenwell Road, London, have devised a handsome and handy inhaler (the carbolic smoke ball) which costs very little compared with the great good done in all catarrhal diseases. For further particulars apply to Messrs. BARKER BROTHERS, 150, Dharamtala Street, Calcutta.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Surgn.-Lieut.-Col. James Charles Harding Peacocke, I. M. S. (Bombay), Civil Surgn., Karwar, is permitted to retire from the service, from 14th May 1898.

The undermentioned senior Asst. Surgns., I. S. M. D., are permitted to retire from the service, from the dates specified:—

Hony. Surgn.-Capt. Joseph Holmes (Bengal), 17th Feb, 1898.

Hony. Surgn.-Capt. Francis Green (Madras), 9th Sept, 1897.

Surgn.-Lieut.-Col. Percy deHaga Haig is granted the temp. rank of Brig.-Surgn.-Lieut.-Col. from 9th Aug. 1897.

The services of Brig.-Surgn.-Lieut.-Col. A. M. Bramfoot, M.D., I. M. S. (Madras), are replaced at the disposal of the Mil. Dept., from 28th April 1898.

Mily. Asst. Surgn. Charles Reginald Washington Bancroft, having passed his dept. exam., is entitled to the enhanced rate of pay of his class, from 15th April 1897.

BENGAL GOVERNMENT.

Surgn.-Capt. C. R. M. Green to act as Supdt., Campbell's Med. School and Hosp., Sealdah.

Surgn.-Major A. H. Burlton, A. M. S., Stn. Hosp., Dum-Dum, to have charge civil med. duties at that station from 6th Jan.,

Surgn.-Capt. H. W. Pilgrim to act as Civil Surgn. of the 24-Parganas.

Surgn.-Capt. D. M. Moir, second Bandt. Surgn., Presy. Genl. Hosp., Calcutta, to act as First Bandt. Surgn.

The services of Miss M. M. Tyrell Christie, M.D., an Inspg. Med. Officer at Chacra Station, B. I. R., are placed at the disposal of the San'y. Commr., Beag.

Assam. Surg. Ananda Prasad Ghosh, Rangpoj sub-div. and Dipty, to have temp. med. charge Bardwan Dipty.
 Asst. Surg. Suresh Chandra Banerjee, Asst. Supdt. of Immigration at Rangpoj and Assamole, to have temp. med. charge Rangpoj sub-div. and Dipty.
 Asst. Surg. Chunder Coomar Gupta, Bardwan Dipty. leave for three months.
 Asst. Surg. Satia Chandra Basu, Puri Dipty., did supy. duty Med. College Hosp., from 15th to 30th April 1898.
 Asst. Surg. Jogendra Nath Ghosh, Teacher of Midwifery, Campbell Med. School, leave for two months.
 Asst. Surg. Devendra Nath Roy, Teacher of Medical Jurisprudence, Campbell Med. School, leave for two months.
 Asst. Surg. Bhola Nath Pal, a supy. Med. Coll. Hosp., leave for three months.
 Asst. Surg. Maseo Mohun Gupta to do supy. duty Med. Coll. Hosp., Calcutta, from 16th April 1898.
 Asst. Surg. Sarat Chunder Sur, a supy. Med. Coll. Hosp., to have temp. med. charge of Kishoreganj sub-div. and Hyabaturgar Dipty., Mymensingh dist.
 Asst. Surg. Surut Lal Basu, Kishoreganj sub-div. and Hyabaturgar Dipty., leave for three months.
 Asst. Surg. Kasi Nath Ghosh, Bismestipur sub-div. and Dipty., leave from 24th June to 2nd July 1897, in extension of that granted to him on 15th May 1897.

PUNJAB GOVERNMENT.

Asst. Surg. Inayatulla Nadek, Sader Dipty., Gurdaspur, is placed in med. charge Gurdaspur, from 16th April 1898.
 Asst. Surg. J. T. Weston resumed charge civil med. duties of Hissar, 15th April 1898.
 Asst. Surg. J. T. Weston, Civil Surg. of Hissar, is deputed on special duty in connection with the plague, Jullundur dist., from 19th April 1898.
 Asst. Surg. Hardial Singh, Gujrat Dipty., is placed in civil med. charge Gujrat dist. from 8th April 1898.
 Surg.-Major L. T. Young, Civil Surg. of Umballa, has obtained furlough to Europe for six months.
 Surg.-Major M. J. Sexton, A. M. S., is placed in civil med. charge of Dalhousie, from 17th April 1898.
 Surg.-Major L. T. Young, Civil Surg., to officiate as Civil Surg., 1st class.
 Surg.-Lieut.-Col. A. W. Mackenzie resumed charge civil med. duties of Abbottabad, 16th April 1898.
 The services of Surg.-Major J. A. Cunningham, M.D., M. Ch., L.M.S. (Bengal), are replaced at the disposal of the Govt. of the Punjab.

CENTRAL PROVINCES GOVERNMENT.

Hosp. Asst. Bankrishna Apaji, Murwara Branch Dipty., Jabulpore dist., held charge of the Murwara Poor-house from 2nd Nov. 1897 to 15th March 1898.
 Hosp. Asst. Bankrishna Apaji, Murwara Branch Dipty., Jabulpore dist., was deputed on plague duty, Katni Ry. Stn., from 1st Jan. to 30th March 1898.
 Hosp. Asst. G. Ramiah Naidu, doing plague duty under Insp. Med. Officer at Itarsi, to Venkatapur Dipty., Chanda dist.
 Hosp. Asst. Vithal Raghola Landay to Banda Poor-house, from 5th Sept. to 10th Dec. 1897.
 Hosp. Asst. Vithal Moreshwar to Rehi Poor-house, from 1st Dec. 1896 to 30th March 1897.
 Hosp. Asst. Behari Lal to Bardi Poor-house, Jabulpore dist., from 24th Aug. to 22nd Oct. 1897.

N. W. P. & OUDH GOVERNMENT.

Brig.-Surg.-Lieut.-Col. W. A. May, A. M. S., officiated as Civil Surg. Maini Tal. from 4th to 23rd April 1898.
 Surg.-Major E. Hudson, Supdt. Central Prison, Benares furlough out of India for one year from 25th April 1898.
 Surg.-Capt. H. B. Melville, Civil Surg., on return from milly. duty, to Etawah.
 Surg.-Capt. J. Morwood, Civil Surg., on return from milly. duty, to Haridol.
 Surg.-Capt. L. G. Fiesche, Civil Surg., on return from milly. duty, to Basti.
 Surg.-Capt. J. M. Crawford, Civil Surg., on return from milly. duty, to Muttra.
 Surg.-Major G. H. Baker, Civil Surg., on return from milly. duty, to Gorakhpur.
 Asst. Surg. Sri Ram, to Lalitpur Dipty., in Jhansi dist.

BURMAH GOVERNMENT.

Asst. Surg. Maung Chit Tun, assumed charge duties of Civil Surg., Thabon dist., 14th April 1898.

Step. Asst. Bam Lai Chit Tun, assumed charge duties of Civil Hosp., Bhamo.
 Hosp. Asst. S. Abdul Majid, assumed charge duties of Civil Hosp., Upper Chindwin dist., 22nd March 1898.
 Hosp. Asst. Mahomed Sherif, is granted an extension of three months and four days' leave from 16th June 1898.
 Hosp. Asst. Mahomed Sherif, assumed charge as a supy. at the Genl. Hosp., Rangoon, 22nd April 1898.
 Hosp. Asst. Lakhim Kanta Bose, assumed charge Police Hosp., Kamaing, Mogaung sub-div., 10th April 1898.
 Hosp. Asst. Lakhim Kanta Bose assumed charge Civil Hosp., Kamaing, Mogaung sub-div., 10th April 1898.
 Hosp. Asst. Maung Aung Pru assumed charge Police Hosp., Pakokku, 13th April 1898.
 Hosp. Asst. Maung Aung Pru assumed charge Jail Hosp., Pakokku, 13th April 1898.

G. O. O. C.

The undermentioned Hosp. Assts. qualified themselves for promotion to the next higher grade and are entitled to the pay of the same:—

Bishesar Nath Sukul, Pohlo Bam, Shaker Abdus Khan, Imdad Hussain Khan, Ali Naki, Saiyid Turab Ali, Inayat Khan, Nizam-ud-din, Dhondli Nagooji Vengay, Bakhtasna Khashinath, Gopal Narayan and Shaik Mohideen.

ASSAM GOVERNMENT.

Hosp. Asst. Rajani Kanta Karmakar, a supy. Goalpara dist., to Darrang dist., Sipajhar Dipty., from 5th April 1898.
 Sick leave for two months is granted to Hosp. Asst. Jamini Kumar Ghosal, Dipty. and Look-up Barpeta, from 18th April 1898.
 Hosp. Asst. Raj Mohan Ganguli, Sipajhar Dipty., Darrang dist., to Kamrup dist. Dipty. and Look-up at Barpeta, from 12th April 1898.

Sick leave for six months is granted to Hosp. Asst. Kailas Chandra Das, Jaluguti Dipty., Nowgong dist., from 1st Feb. 1898.

Babu Sarada Mohan Bhattacharyya is appointed for six months a Civil Hosp. Asst. in Assam and posted to Sibsagar for duty as supy. from the 29th April 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Re. 1 for subscribers and Re. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

MARRIAGES.

EVANS—HOWSE—On the 15th April, at the Church of All Hallows, Londondal, E. C., by the Rector, the Rev. E. J. Stone, cousin of the bridegroom, Harold Ward Evans, M.R.C.S., L.R.C.P., of Littleport, Camba, younger son of the late Francis Stone, Evans, Esq., M.A., late Principal of the Presidency College of Madras, to Hilda Mabel, fourth daughter of the late Alfred Howse, Esq., M.R.C.S.

BARNES—DISSENT—On the 23rd April, at the Free Church of Scotland, Calcutta, by the Rev. David Reid, James Fitz-Ernest Barnes, to Florence Hope Dissent, M.D.

WHITTENBURY—KNIGHT—On the 2nd May, at the Fort Chapel, Bombay, Miss Margaret Marie Knight, to Mr. Joseph Henry Whittenbury, Assistant Surgeon, Mhow. (No cards.) (English papers, please copy.)

NOTICES TO CORRESPONDENTS.

A. B. E.—Despatch a sample of the food to the Editor, *Indian Gardening*, Elliott Road, Calcutta, giving particulars for its preparation. Do the same to the Chemical Examiner to the Government of Bengal. Send another sample to the Director-General of Agriculture in India, Simla.

A. D. M.—Many thanks.

J. B.—The papers in connection with the Imperial Anglo-Indian Association will be published shortly and will be distributed broadcast over all India.

C. C. G.—Your case is a hard one. You ought to re-join college and put in your full course.

A. L. M.—Special plague allowances have already been granted. Look up your back numbers of the Record.

M. S.—The papers you have sent prove that Military Hospital Assistants undergo a very fair training in medicine.

ORIGINAL ARTICLES.

CLIMATE AND MALARIA.

III.

BY SURGEON-MAJOR R. R. H. MOORE, M.D., A.M.S.
Jalapaht, Darjeeling.

It is well known that forests have the power of conserving the moisture of a district, and that the soil under trees is always damper than the soil of open spaces.

This leads us to the consideration of another set of important phenomena.

When woods are cut down upon a large scale, the excess of moisture accumulated by their presence is released, the cause which preserved it in that particular spot is removed, what happens? What are the immediate and ultimate results?

The immediate result is that a large surface is suddenly laid bare, containing a larger amount of water than it can dispose of, and larger than a bare space of land under the same circumstances could contain: in other words, the deforested land is in the first instance a swamp.

In time of course this rights itself; the excess of moisture is removed, either by sub-soil drainage or evaporation, and the land gradually assumes the characters of neighbouring bare places, and becomes as dry as if it had never been covered by trees.

What more natural than that an outbreak of malaria should mark the period of deforesting, and that this should gradually subside and a healthy condition be restored?

This is the natural sequence of events, and this is the simple explanation of those numerous and extensive epidemics of malaria which have so often been reported in the United States, when trees were removed from the whole face of the country.

This however is a matter which has never received the attention it deserved, and which has never been carefully or scientifically investigated; so much so indeed that, as far as I am aware, this explanation, simple and obvious as it appears to be, has never previously been even suggested.

The idea is undoubtedly held by many that in malarious countries, woods are unhealthy. I believe this idea has entirely arisen from the fact of the general dampness of the soil, and of the general association of dampness with malaria.

TOMMARI-CRUDELI in this connection says:—"Woods covering malarious ground may favor the production of malaria by preventing evaporation and preserving moisture in the surface soil." He also says:—"If the layer of soil is thin the removal of the wood will help the sun to dry it."

This is of course all theory; for not a single instance is brought forward in support of the notion that when malaria prevails in a forest, the clearing of the trees will remove it.

It is a subject for regret that there is such a scarcity of reliable observations on this point from which to draw deductions, but the reader will have far to

search before he finds a well-authenticated case of a malarious and thickly wooded district being rendered healthy by the complete clearance of the trees.

All woods are damp, but all woods are not malarious, therefore something else must be looked for beyond the mere dampness to account for the malaria when it is present; again afforesting must induce dampness of soil, yet we have seen that in Italy it is highly lauded as a prophylactic against malaria.

There is, I think, sufficient evidence of the benedict action of trees in malarious places, in sub-tropical and temperate climates to warrant my putting it forward as a general rule that in such climates trees always antagonise malaria, while their removal has the contrary effect. To assume that such a rule should be without exceptions, would be to assume that this rule must be an exception to all other rules.

Regarding exceptions. I may say that I think all cases of malarious woods should be carefully investigated; it by no means follows because a forest is malarious that the removal of the trees in toto will affect a cure. Many other things may have to be considered, and in the absence of exact data the subject is not an easy one to discuss.

Probably the most notorious of malarious forests is the Terai, but there is reason to believe that this region is not nearly so deadly as it is often made out to be.

I have it on the authority of two Darjeeling Civil Surgeons that in the cleared portions of the Darjeeling Terai, Europeans can live without contracting fever.

One of them, Dr. T. DUKE, writes:—"Those planters who have well built houses to live in, affording due protection particularly at night during sleep against these sudden changes of temperature, are known to keep their health in the Terai, even as well, as almost in any part of the plains of India."

This is another example of what I have several times drawn attention to, namely, the marked way in which malaria avoids a well built house. Dr. DUKE continues:—

"The shanties above mentioned are not only inadequate as domiciles, but they are positively dangerous to live in, considering the climate. The nights in the Terai are, as a rule, very draughty, and there is a great difference at some seasons between the temperature of the day and at night, which in the latter case is still further lowered by the sharp breezes which often sweep through the 'shanties' in every direction from the sides and from the top, as well as from below."

To travellers camping there at night without sufficient protection the Terai is very deadly.

Another curious point about this district is mentioned also by Dr. DUKE. He says:—"In the sanitary report furnished by my predecessor for 1868, it is stated that Europeans living in malarious places (tea plantations at a low elevation are meant) never get fever except when visiting Darjeeling."

Dr. SEALE of Darjeeling, who has had an extensive personal experience, both of the Terai and of Darjeeling, bears witness to the truth of this statement, though not inclined to put it quite so strongly.

Cases like this are frequently put forward as proof of

an incubation stage, that they prove nothing of the kind appears to me too obvious to admit of discussion.

They only prove the paradox that people can contract malarial fever where it is generally admitted that there is no malaria.

Given the fact that Europeans can live with impunity in the cleared portions of the Terai when well housed, would we be justified in advocating the clearing of the whole of the district?

By no means, for the fact that people can live in health under such circumstances is no proof that the malaria has been banished, on the contrary we have unmistakable evidence that it is not banished, for those living in "Shanties" suffer in an extensive degree. What is the explanation of this apparent contradiction? It is only the question of exposure, which I have already dealt with in this journal for 16th March 1896.

It is difficult, if not impossible, to believe that a poison diffused in the atmosphere, and capable of being carried from place to place by the wind, or by any other agency, could make such distinctions.

It is evident that malaria is not exterminated by these clearings, therefore there is no reason to believe that clearing the whole Terai would drive it away. In my opinion it would, on the other hand, make matters much worse.

The climate of the Terai presents important peculiarities whose full value must be carefully weighed. They are due to its situation, to the towering range of the Himalayas which springs from its northern boundary.

We read that "the nights in the Terai are very draughty," and subject to "sharp breezes," the cause of these cold currents of air is to be found in the situation, and they depend upon certain physical laws which have a large bearing on climate.

I have mentioned that the effect of nocturnal radiation is to cool and raise the specific gravity of the air in contact with the earth. What is the result?

To quote from the *Encyclopædia Britannica*—"Valleys surrounded by hills and high grounds not only retain their own cold of radiation, but also serve as reservoirs for the cold, heavy air which passes down upon them from the neighbouring heights; along low-lying situations, in the valleys of the Tweed and other great rivers of Great Britain. Laurels, Araucarias and other trees and shrubs were destroyed during the great frost of Christmas 1860, when the same species growing on relatively higher ground escaped."

"Hence mist is often formed in low land, while slight eminences are clear."

Respecting a mountainous country, the experiments made in Switzerland are of special value. "In Switzerland it is observed in calm weather in winter, when the ground becomes colder than the air above it, that systems of descending currents of air set in over the whole face of the country. The direction and force of these descending currents follow the irregularities of the surface, and like currents of water they tend to converge and unite in the valleys and gorges, down which they flow like rivers in their beds; on such occasions the temperature of the tops of mountains and high ground is relatively high. In ris-

ing above the current of cold air is a falling the temperature of temperature is readily felt."

In the Terai these conditions must, as a rule, be much accentuated; the great difference between the temperature of the Terai and of the lofty mountains increasing the force with which the cold air from the latter rushes down the ravines at night, "causing the icy blasts so often experienced at the mouths of ravines and gorges."

Trees break up, and shelter from these cold currents, to remove them under such circumstances would be to alter the climate in such a way that it would be much worse than before.

There appears to be absolutely no evidence to convict trees of playing any part in the dissemination of malaria.

Some people are greatly prejudiced against the presence of trees or shrubs in close proximity to dwellings. Dr. MEREDITH, who interested himself particularly in this subject, and who had extensive experience in British Guiana and in Assam, says as follows:—"I consider shrubberies, bushes, plants with the character of trees, but growing only from 2 or 3 feet to 10 or 12 feet in height, healthy, and in moderation desirable about dwellings." "One noteworthy instance of the advantage of a well-kept garden, I may" he says "mention, that of a merchant in George Town, (British Guiana). He had taken great pains to drain what in India could be called his compound, and having drained it, he laid the ground out with a profusion of shrubs and bushes of various sizes and descriptions, it was attended with marked improvement in the healthiness of the place." "Instead therefore," he concludes, "of taking it as an axiom that brushwood is almost always bad, I am decidedly of opinion, all other matters being regular, that the reverse is the case."

Significant as these remarks are, they conceal a fallacy due to the general looseness of language in which many writers on malaria rejoice. "Brushwood" has been condemned as malarious time out of mind by an uninterrupted chorus of authors, but none of them have paused to tell us exactly what they meant by "brushwood"; the word, as it stands, has no definite meaning at all; in fact may mean a bundle of branches cut off from a tree. Why then has it been passed on and re-echoed from one to another, unless we are to conclude that the vagueness of language is the result of vagueness of ideas?

That Dr. MEREDITH should suppose the term is applicable to well-kept shrubs in a carefully laid out garden shows that some definition is necessary.

How then is the distinction to be drawn, to show that all observers may be in the right, and not contradicting one another.

We frequently hear of healthy and unhealthy vegetation, but what meanings do the terms imply?

The nature of the vegetation depends on the most part (leaving climate considerations aside) on the nature of the soil, healthy vegetation will spring from a healthy soil and unhealthy from an unhealthy soil. A healthy soil is a well drained soil, and vice versa.

The vegetation of a swamp is unhealthy; the rank undergrowth of many forests is unhealthy; rank undergrowth, well marked in the Terai, is associated with

moisture of the soil; this is the extreme degree of moisture which is the cause of the malarialism and the undergrowth, probably tends to check it more than anything else.

Whether in sub-tropical climates there is a large amount of moisture there is certainly to be a luxuriant vegetation. Luxuriant vegetation is an index to damp soil, and a damp soil is unhealthy.

The removal of "brushwood" has frequently, and especially in connection with the laying out of camps, been accused of producing malaria. Well it is hardly fair, when one gets malarial fever from lying on a damp soil, to put it down to the credit of the vegetation that was removed to make a space to lie down in; for in these cases two things are fairly evident, first that the ground occupied by such growth was damp, second that no one would have taken the trouble to remove it, had the ground not been wanted for the men to camp on.

RAVINES.

In malarious countries ravines and punch-bowl valleys have long enjoyed an unenviable notoriety for being extremely malarious; in these places the air movements are identical with the movements already described as taking place in Switzerland and in the Terai. At the bottom of such valleys there is a broiling sun all day, succeeded at night fall by a downpour of cold air from above, and cold gusts of wind in the ravines.

I allude to this matter here in connection with the enormous extent to which our troops suffer from malarial fever when engaged in active service in the hills on our Indian frontier.

In the recent Tochi Expedition, I have it on the best authority that malarial fevers accounted for almost the whole of the enormous sickness, and actually disabled a whole regiment.

In the Chitral Relief Force in 1895, the admission rate for intermittent fever amongst European troops was 513.4, though this figure falls much below the average of several Indian stations, especially those in the Punjab, it has still to be taken into consideration that the troops in active service are all picked men.

An admission rate of 513.4 is very high for such a body of men from which all those debilitated or sickly have been removed.

It is not known that the natives of these hills, suffer extensively from malarial fevers, nor can it be maintained that the conditions usually associated with malaria prevail more in these hills than in the Presidencies of Madras and Bombay.

On the supposition then of a specific poison the explanation of this great amount of malarial fever amongst our troops is still wanting.

On the other hand, it is easily seen that the men must be greatly exposed to extreme vicissitudes of temperature from the causes above stated.

In these campaigns, our troops are of necessity almost invariably obliged to camp in the bottoms of ravines, in which the cold at night as well as the heat during the day are in excess of what they can at higher elevations, to tolerate. In such situations are liable to be much

damp than higher ground. As slightly confirmatory of the phenomenon of cold air flowing down from higher levels and settling in the beds of ravines, I may refer to the third of the series of thermometric observations I made at Darjeeling (see last number of this journal.)

The figures are as follows in twenty-seven observations, the mean minimum temperature at night was 51.1°F, at the bottom of a small ravine 500 feet below the summit of the hill. On an open place on the summit the mean minimum was 50.1°F, while in a small grove of trees it was as high as 54.5°F.

This shows that it was much colder at night in this ravine than it was in the trees on the summit, though the elevation was 500 feet less, while the open space on the summit was only 1°F colder on the average.

As the ravine ran east and west and was in shade most of the day, the maximum temperatures are of no value. The rule, however, is that places on the side of a hill below the summit have a greater diurnal range of temperature than the summit. BLANDFORD says:—Even at one and the same station, houses on the crest of a ridge have a smaller diurnal range of temperature than those on the lateral slopes. Thus at Darjeeling the present observatory, which is on the crest of the ridge, shows a difference of night and day temperatures about 2°F less than the old observatory, which for many years existed lower down (500 feet), on the side of the same hill, and this notwithstanding that the new observatory is more exposed than the abandoned site."

That these cold currents flowing down from higher to lower elevations and collecting in valleys, low lying grounds and ravines have an injurious effect upon health, especially on the health of soldiers exhausted and over heated after a long day's march under a hot sun, cannot be doubted, and from the view of the sanitarian, they deserve much more attention than has ever yet been paid to them.

It requires no great strain on our reasoning faculties to conclude that some connection exists between the phenomena I have just been discussing and the undisputed fact that the malarial poison reigns chiefly at night, and we may turn aside for a minute to consider the explanations that have been given to account for this peculiarity.

One set of authors maintained that the malarial poison was drawn up by the heat of the sun; that during the day it hovered about at some unknown elevation, and when night came it swooped down, as ARMAND humourously says, like a flock of wild fowl to seek the marsh.

The difficulties in the way of accepting this idea were no great—and I will not now waste time in discussing them—that it had to be given up.

There is, however, one point in it which is deserving of attention, the evaporating power of a tropical or sub-tropical sun is enormous, and under its influence a considerable weight of water is drawn up from the soil into the atmosphere; if the germ or poison is in the soil, how is it that it has the power to resist this immense force? On the other hand, if the poison were the result of putrefactive changes, is it not during the day, under the

sation of a powerful sun, that it should be most in evidence?

Undoubtedly it would have been more convenient for these theorists if malaria had been most redoubtable while the sun was up, but this was too obviously not the case, so some other theory had to be found.

It was the custom in the Roman Campagna for farmsteads to be built in the form of a court yard, with all the doors and windows opening inwards, and with the exception of one door for entrance and exit, nothing but a bare wall on the outer face; now the man who let his imagination so outrun itself as to declare to the world that this form of construction was undertaken to keep out malaria, which of course could not get over the wall, rather than as a means of security to the inhabitants and their flocks was evidently predestined for this desperate attempt.

TOMMASI-CRUDELI accordingly not to belie his character, advanced the astounding doctrine that owing to the variations in temperature which occur at sunset, ascending currents are formed which carry the malarial germ out of the soil and disperse it in the lower strata of the atmosphere. Such was his theory, and this theory strange as it may seem, instead of being scouted, buffeted and kicked out of existence as it should have been almost before it had time to breathe, was listened to with respect in the civilised capitals of the world, and reproduced as a solution of the whole matter by one author after another.

But what these wonderful ascending currents of CRUDELI were no man has ever been able to discover.

The fact is in this idea of CRUDELI's the simplest physical laws are ignored or denied.

At sunset the earth cools quicker than the surrounding air; therefore the air in the interstices of the earth cools and contracts, and far from rising has a tendency to sink, while other air from the outside comes in to replace the loss by shrinkage. Further from the surface of the earth upwards, every succeeding strata is warmer and lighter than the one below it, and all are tending to grow cooler and therefore heavier, yet in spite of all these adverse circumstances, like love that laughs at the locksmith's art, CRUDELI's germs that all day long were unmoved by the burning glances of APOLLO, start forth at nightfall on the airy wings of imagination, and dance like fairies on the sward.

Such are the theories that have been propounded to account for the nocturnal habits of malaria.

CULTIVATION.

There is one other point to be considered here; a great deal of emphasis is laid at the present time on the necessity for cultivation before land can be freed from malaria. I cannot however discover the exact idea that lurks in the brains of those who lay so much stress on this point.

The word cultivation is usually paired off with drainage—"drainage cultivation, etc." we read, have made lands healthy. There is some tallman in the word cultivation; it seems to be possessed of some occult powers, but what the powers attributed to it by the writers are I know not. KILSON and KEMNER say:—"Marshes that have been

dried or filled up, and lands that have been drained only, become really healthy when the soil is subsequently exhausted by continuous cultivation. So essential is this, that it ought to be as much enforced by law upon owners of land, as the proper maintenance and care of salt marshes are upon the companies who work them."

According to this the proprietor of land is to be forced to exhaust it, a pleasant prospect truly, and one to which we can easily imagine he would not readily submit; but we are given to understand that if he does not exhaust it, it cannot be healthy, truly a pretty dilemma for the landed proprietor.

Further we are given no clue to the kind of cultivation, and it is somewhat of an embracing term; for instance, would rice cultivation be likely to be beneficial, or irrigated meadows? The state of the cultivation, in my opinion, may be simply taken as an index of the state of the soil, crops as a rule do not thrive in a marsh, and when we see a good crop of wheat or potatoes, we are justified in the conclusion that the soil is a dry one. Furthermore, good grass land is generally healthy, yet it cannot properly be called cultivated land.

Beyond this I cannot imagine what else authors, who held such general views as KILSON and KEMNER, can see in cultivation, marshy land is drained, by this process it is made available for cultivation, and is cultivated accordingly, and becomes healthy, but it is the drainage which rendered the land fit for cultivation which also made it healthy. Are there any instances of land well drained being left uncultivated with the result that they still continued malarious? On the other hand, however, land covered by vegetation does influence the local climate. The influence being of the same kind that is exercised by forests but less in degree according to the nature of the vegetation.

"The essential difference between the climates of two countries, the one covered with vegetation and the other not, lies in this: that the heat of the day is more equally distributed over the twenty four hours in the former case and therefore less intense during the warmest part of the day." Such is the climatic difference to which, of course, these authors would not attach the least importance, and it is brought about in this way: the vegetation forms a screen as it were between the earth and the sun, reducing the amount of heat the earth takes up by radiation on the one hand during the day, and gives off during the night, the cooling process during the day is further aided by evaporation of a certain amount of moisture from the leaves of plants.

—:O:—

HOW DIABETIC PATIENTS DIE, AND HOW THEY OUGHT TO LIVE.*

BY P. LE GENDRE, M.D.

Professor Agrégé at the Medical Faculty of Paris, Physician to the Paris Hospital.

DANGERS unnumbered beset the path of the diabetic person, though death is rarely the direct result of diabetes. In so-called pancreatic diabetes the patient sinks and dies in consequence of increasing marasmus and demutrition; but the glycosuria of patients with pancreatic

* Being a clinical lecture delivered at the Tumor Hospital, Paris, France, and specially reported for the *Indian Medical Record*.

known (diabetic neuropathy or amyotrophy) can hardly be viewed as diabetes, since patients affected with degeneration of the pancreas are hopelessly doomed to helpless decay within the space of a few months, and they are not included when insisting on precautions to be taken by diabetic persons to escape the dangerous complications that portend the lives of most of them.

The disease of persons affected with general disorder of nutrition, becoming incapable of burning up the sugar produced by the glycogenic function, inhibits the normal function of the nervous system regulating nutritive metabolism, and this may be the consequence either of a hereditary arthritic diathesis or of some primary lesion in the nervous centres themselves.

This arthritic diabetes polymorphic in its manifestations, is so insidious in its origin and variable in degree, that it escapes suspicion by practitioners who do not systematically analyze the urine of all their patients; yet it frequently permits its victims to live for a long time if they only follow medical advice and regulate their life habits: still it is our solemn and bounden duty to warn such patients that they are always on the verge of an abyss into whose depths they may be precipitated at any moment.

Dangerous nervous complications frequently environ diabetic patients and carry them off in coma or collapse, the starting point of which may be professional or cerebral strain, or some operative or traumatic shock.

One of my masters, a specialist in mental diseases, a prolific writer and a popular lecturer, like many other medical men, took absolutely no care of his own health and refused to have his urine analyzed for sugar, though he presented all the outer aspects of the diabetic taint, and he latterly complained of an unusual sense of fatigue. One evening he went to bed earlier than usual, but being unable to rise next morning, he sent for me. I found him expressionless and drowsy with marked paresis in all four limbs and a good deal of dyspnoea, without, however, any stethoscopic sounds, but the coma progressed continuously and he died peacefully some 24 hours later. The urine passed during the night preceding the morning he sent for me, contained 400 grammes (i.e., 14 ounces) of sugar.

Shock may hasten the end. A patient I had had under observation for several years first came to me for advice about a fall he had had in the streets. I tested his urine and found glycosuria; but he professed most absolute unconcern for my warnings. He several times fell in the streets and getting off with a few insignificant scratches was able to walk home, resignedly; but one day he was picked up helpless, and taken first to the hospital and then to his own house, where my colleague, Dr. QUENU, saw him. There was neither fracture nor dislocation, and nothing beyond a few trifling scratches and contusions. Nor were there abdominal symptoms beyond one involuntary defecation; but there was auria with a low temperature (35.5° C.) and the patient seemed utterly indifferent and unconcerned as to possible consequences of his fall. Injections of artificial serum failed to restore consciousness, and 46 hours after the fall the patient died quietly. This was really a case not of diabetic coma, but of shock or of collapse.

In another case of collapse of a diabetic patient who had been hurt, the existence of glycosuria was ascertained a few days before the accident; but, from that time to the time of his death no trace of sugar could be detected in his urine. The urine was not suppressed, the patient fell into a dying condition accompanied by complete muscular resolution.

That proper hygienic precautions can secure fairly long life to the diabetic was verified by an intelligent chemist of very high professional rank, who was 50 years old when he accidentally discovered he was diabetic. He studied the disease closely, and shunning all nervous excitement so carefully regulated his emotions and his pleasures that, though he was still glycosuric, he enjoyed excellent health up to the age of 60, when grief tipped the beam of the balance and the arterio-sclerosis, hitherto quiescent, began to reveal itself in (1) dyspnoea, (2) albuminuria which slowly became serious, (3) oedema about the malleoli, and (4) then infarctus. The sugar and albumen resisted all curative attempts, but he might have dragged on for a while longer only for a trifling surgical interference with an otitis which developed as a complication of his influenzal attack and refused to yield to medicines. Within a few hours after the operation by one of the most qualified specialists the patient fell into a comatose state from which it was impossible to rouse him and he died. I do not wish to infer that no surgical operation should be performed on a diabetic, as cataracts have been successfully removed, gangrened limbs amputated, furuncles and abscesses incised, &c. in such cases, but I do maintain that indispensable operations alone are to be risked as the issue is always uncertain.

The *weak points* in diabetic individuals are the liver, kidneys and blood vessels.

Some pathologists consider the liver as the pivot of the morbid process, and in the majority of diabetics it is enlarged from nervous hyperæmia or hypertrophy from increased cellular activity, more especially in polyphagic persons, and particularly so if alcohol is largely indulged in: cirrhosis of the liver is one of the epiphenomena of diabetes.

Overworked by incessant elimination of sugar and of the toxins produced by imperfect nitrogenous destruction the epithelial cells become the seat of hyaline degeneration, glycogenic infiltration, and necrotic lesions frequently leading to albuminuria in diabetes and ending in uræmia.

The various changes in the circulatory apparatus for the most part take place around the arteritis putting the tissues in a state of hypo-nutrition and rendering them favorable culture media for every variety of micro-organism, which easily set up grave complications. Gangrene from ischæmia is always one of the most serious complications threatening diabetes. Angina pectoris occasionally occurs and endo- and peri-carditis sometimes cause death.

Danger of tuberculous infection in densely populated areas particularly threatens the diabetic whom it invades insiduously, and then in the majority of cases breaks out and evolves with great rapidity. When the tuberculosis fully develops, the sugar often disappears from the urine by the pyrexia activating the various oxida-

tions. Thus last year I had to deal with a polydipsic, polyphagic and polyuric commercial traveller who weighed 106 kilogrammes (233·89 lbs.) though he had distinct arthritic heredity, and for the past 15 years passed 40 grammes of sugar per litre of urine (i. e., nearly 18 grains to the ounce) while he was in the habit of taking 20 glasses of alcohol daily. Suddenly his appetite vanished, he lost vitality, his vision became blurred, and his legs weak, while his obesity decreased by 40 kilos (i. e., 88·16 lbs.), in one month. Then the signs of consumption positively showed themselves, the polyuria and glycosuria vanished, and in less than five months he was dead.

Rapid evolution is the rule, still a tuberculous diabetic may live for many years. I knew a general officer who died at a comparatively advanced age, though his tuberculosis and diabetes began when he was a sub-lieutenant and in the last months of his life traces only of sugar were found in his urine.

The pneumococcus is a source of danger, and the pneumonia may evolve in a remarkably insidious way and run through its deadly course at most without fever. One of my patients, who was slightly diabetic, was very rapidly carried off by pneumonia, though he hardly coughed at all, and seemed unconscious of excessive dyspnoea.

The streptococcus and staphylococcus carry off many diabetics by inducing suppuration in regions favorable to furuncles and abscesses. One of my lady patients, who had an extremely mild attack of facial erysipelas which led to suppuration of the parotid gland, died of profound asthenia after the abscess was drained; but in another woman, who was passing 185 grammes (nearly 6·6 ounces) of sugar every 24 hours and had suffered from furuncles in various parts of her body, the suppuration was less unfavorably located in her lumbar region. After keeping her on anti-diabetic treatment for a few days, the anthracoid mass and its numerous diverticula were freely laid open and emptied and moist antiseptic dressings applied. She mended rapidly and 42 days after the operation the wound was completely healed and the sugar went down to 20 grammes (30·9 grains) a day.

Excess in drugs and alcoholic drinks are two common iniquities that ought to be carefully guarded against. Most patients get frightened as soon as their diabetes is revealed to them and eagerly enquire right and left as to the best remedies. They exhaust the list of specialities recommended by their friends or advertised in their daily or other 'papers' to despairingly find their improvement, if any, is only temporary and gradually growing tired of everything finally refuse even to observe diet which is their sheet anchor. Then under the mistaken idea that they require general 'tonics,' too many diabetic patients drink wine, ale and alcohol freely, or they go in largely for 'medicated wines' which are carelessly advertised as being able (??) to arrest wasting or to increase strength; but which do more harm than good even though their formulae are legion and some of them actually bear the signature of professional men or are 'backed' by some of the medical journals.

Individual study of each case is requisite as the result of treatment depends upon a goodly number of influences

quite distinct from the nature of the diabetes itself, and his employment and habits and the way of thinking of those habitually in contact with him very often are so many obstacles to the success of the rules of living, that he must observe closely if he wishes to get well, or at least to live along with his diabetes without losing ground.

The best regimen for the diabetic is:—(1) Early to bed and early to rise at a regular hour. (2) Friction all over with a horse-hair glove every morning before dressing. (3) Before going to bed rub himself with a woolen glove impregnated with some aromatic tincture. (4) According to the season of the year practice hydrotherapy, as keeping the skin clean not only prevents skin affections and microbial invasions, but also insures the proper working of the glands and the activity of the circulation, as well as exerts a favorable influence on nutritive changes through the influence of peripheral expansion of the nervous system. (5) Physical exercise, which must be so regulated that it just suffices to activate the respiratory movements and increase oxidation and no more, as when it passes into fatigue exercise becomes injurious in a variety of ways. It is most convenient to advise 'merely walking,' but the exercise may take the form of riding, shooting, cycling, housework, gardening and a variety of open air games, according to the age and condition of the patient and his apparent power of resistance, but the patient must beware of the temptation to overdo it and of consequent cold. (6) After each meal the mouth and teeth must be cleaned with antiseptic gargles and tooth powders. (7) Carefully regulated diet. (8) Minute toilet care of the genitals. (9) No wound, be it even a tiny scratch, ought ever to be treated lightly. And (10) all accidental catarrhs of the respiratory passages must be got rid of as speedily as possible.

The question of diet has always been a vexed question, the answers to which are multiple and often apparently contradictory; but if the patient has not reached the stage of consumption and there is nothing in his urine to justify any fear of auto-intoxication or of coma, put him for ten days on CANTANI's sarco-adipose test-diet, which exclusively consists of meat, fish, eggs and fat, with only water to drink and sometimes a little wine or coffee, minus sugar. If this severe diet does away with the glycosuria, the progress of the diabetes may be checked without the medicinal intervention that is necessary in more severe cases; but as it leads to satiety and disgust from too much uniformity or to dyspepsia from exclusive ingestion of quaternary food stuffs, the CANTANI diet must not be continued too long and must give way to a more varied diet with the smallest possible quantity of sugar-producing substances. Therefore allow:—

Soups made from meat-broth, yolk of eggs and vegetables.

Meat, the quantity of which should range from 400 to 500 grammes (i. e., 14 to 17 oz.) daily, may consist of beef, veal, mutton, poultry, game, sweet-bread, grubs, smoked meat, ham, pork (not often), and should include from 100 to 300 grammes (3·5 to 7·02) of fat daily.

Fish of every description, whether fresh, salt-water or shell-fish and mollusks (but not oysters) and whether fresh or preserved in oils may be recommended.

Vegetables.—Asparagus is looked upon with suspicion and sweet potatoes especially, interdicted, while cabbage may sometimes be indulged in, but artichokes, Brussels sprouts, cauliflower, French beans, salinity, sorrel, sourknot, and spinach may be freely eaten, provided they have been well boiled in water and properly drained before use or being made up with cream, meat juice or yolk of egg. All the herbaceous greens, such as corn-salad, dandelion, endive, lettuce, &c., are allowable and may be eaten cooked or raw.

Dessert may include almonds, filberts, olives, pistachio nuts, walnuts and every variety of cheese.

Opinions are divided as to the use of fruit, the less saccharine varieties of which may be tolerated in the slighter cases of diabetes; but cherries, dates, figs, grapes and melons must be forbidden.

The matter of bread has been a theme for considerable discussion, but most modern authors agree that ordinary baker's bread is harmful as it usually contains 60 per cent. of sugar, while gluten bread with its 20 per cent starch and from 27 to 31 per cent. sugar is unpleasant to taste and hard to chew, insalivate and digest. PAVY and SEBEN's almond bread is expensive and, like PROUT's bean bread, heavy to digest, while Echaude and soja hispida bread contain 40 to 50 per cent. of carbo-hydrates. ENSTEIN's aleuronat, which contains 50 to 60 per cent of albuminoid substances and a little starch, is pretty extensively used in Germany but hardly as yet in France, where we allow 100 to 150 grms. (3.5 to 5.2 oz.) of boiled potatoes, or 150 grammes (5.2 oz.) of boiled potatoes and 25 grammes (0.88 oz.) of bread-crumbs as prescribed by ROBIN; but DREYFUS-BRISAL, DUJARDIN-BEAUMETZ and LECORCHE advise 40 to 80 grammes (1.4 to 2.8 oz.) of the crust only.

"Drink to your thirst" is rightly advised to the diabetic patient, who must ingest a certain amount of liquid to drain out the excess of sugar contained in his blood, but that liquid should be water or unsweetened aqueous infusions of quassia bark, chiretta, or small centaury. Alcohol, ales, beers, cider and sweet wines should be especially forbidden. If he will insist on taking wine, let him use the drier and unsweetened varieties, and even this with extreme caution and moderation, because of the propensity of the liver to cirrhosis.

Milk, when it does not increase the glycosuria (check maintained by regular analysis of the urine) proves of great service to the diabetic patient suffering from cirrhosis, renal lesions, or cardiac complications with disturbed compensation. Besides which milk is an article of food that often renders the "special diet" more readily borne.

I believe the medicinal treatment of diabetes to be of secondary importance only, and I agree with TROUSSEAU that with sound hygienic and diabetic measures, aided by a few drugs discreetly and prudently handled, we may hope to cure a few and relieve a great many diabetic patients.

WHAT OPERATION CAN DO FOR CANCER OF THE TONGUE.*

By HENRY T. BUTLIN, F.R.C.S., D.C.L.

Surgeon to St. Bartholomew's Hospital, London.

With the object of ascertaining (1) the necessity or not of removal of the entire tongue in every case of cancer, and (2) what proportion of the patients die from affection of the neck without recurrence in the mouth, I began last October (1897) to put together all my cases and to search out the further history of the 102 patients I had operated on until 1896. Of these 53 were hospital and 49 private patients.

I have had the good fortune to trace all but 7 of these patients, and knowing that the mortality due to the operation itself was singularly small among my private patients, I thought there would be some difference in the results of the operations in the two groups; but I was quite unprepared for the much more satisfactory results, so far as the cure of the disease is concerned, in the private patients. Thus:—

			Hospital cases.	Private cases.
Died of Operation	9	1
Recurrence in situ	8	10
Affection of glands without recurrence	16	12
Died later of other cause than cancer	4	4
Well within 3 years after operation	2	9
Well more than 3 years after operation	7	13
Lost sight of	7	...
		Total	53	49
		Grand total of cases	...	120

Why are the results of private practice so much better than those of hospital practice? Because the cases are earlier operated on. People in good or moderate circumstances being better educated in the possibility of cancer of the tongue and being more apprehensive of danger, will not put up with the fungating offensive masses of cancer so frequently seen in the mouths of hospital patients, and many of which render large operations necessary, while the straitened circumstances of the victim make it impossible for him to be properly nourished before the operation: so that the chance of recovery from a severe operation is much smaller for the hospital than for the private patient, who also has the additional advantages of special individual attention, good nursing and plenty of nourishment and medical comforts, all of which cannot conveniently be obtained in the open wards of an hospital.

In the majority of the cases that were cured, the cancer was in the anterior two-thirds of the tongue; while, as was expected, those were particularly fatal where the disease was far back in the dorsum or along the border in the neighbourhood of the anterior half arches of the fauces, but there is evidence to show that even some of these cases may be treated with success provided the cancer has not invaded the tonsillar and neighbouring regions.

Had the private patients who were cured without the glands being removed from any one of them at the time

*Being a lecture delivered before the Edinburgh Society on 3rd February 1906, and specially reported for the Indian Medical Record.

of or after the operation of the tongue, formed the sole material for study, it might be concluded that affection of the lymphatic glands renders the prospects of a cure hopeless; but the 7 hospital cases that were cured tell a different tale as in 4 out of 5 of these, who had their glands removed at or after the operation on the tongue, the glands were not only enlarged, but also decidedly cancerous.

II.—The question of the necessity for the removal of the entire tongue is one of considerable importance, and though some surgeons decline to operate for the removal of half or a portion only of the tongue, I am not in the habit of removing the entire tongue as a routine operation in every case of cancer, as it is not only a serious mutilation which creates a difficulty in taking solid food, lets mucous and saliva collect in his oral cavity and, if his occupation depends on speech, deprives the victim of his livelihood, but the operation also, is much more dangerous than the removal of the fore part or one-half of the tongue, and the plea that "a very considerable proportion of the persons who suffer from recurrence in the month would have been preserved from that recurrence had the entire tongue been removed as a routine operation" is scarcely justified by the results obtained. In the foregoing groups of 102 cases, the entire tongue was removed in 16 persons, of whom 4 died of the operation, very shortly after which 2 more died, 5 suffered from recurrence *in situ*, 1 had his glands affected without recurrence, 3 were lost sight of, and one only was really cured. Then local recurrence was observed in 18 only out of 66* of my patients in whom it might have taken place. In 5 of these 18 cases the entire tongue had been removed, while in 7 other cases the recurrence took place in the anterior half-arch of the palate or in the floor of the mouth or in some part which would not have been more freely dealt with even had the entire tongue been removed. In 1 patient too small a portion of the tongue was, inadvertently, removed, and while I might have done wisely in removing the entire tongue in 2 patients, I think a little more than was done would certainly have sufficed for the remaining 3 cases.

Of course when there is no help for it, I do sometimes excise the entire tongue, but as there is ample proof that removal of a portion of the tongue suffices to cure a considerable percentage of patients and to save a much larger percentage from recurrence of the disease in the month, I always aim at removing the cancer with three-fourths of an inch of apparently healthy tissues around it in every direction. When the disease is on the border of the tongue I remove half the tongue to an inch behind the margin of the cancer; but when it is near the tip or forepart of the dorsum, the forepart of the tongue is removed and the results obtained lead me to take so much more hopeful a view of the operative treatment of the disease than I did 10 or 11 years ago, that it seems fair to say that the prognosis of cancer of the tongue, whether it is situated in the substance or in the border of the anterior two-thirds of the tongue, is not by

* Made up thus—13 patients who actually suffered from recurrence *in situ*, 30 who died of infection of the glands without recurrence in the month and 20 who remained well more than three years after the operation.

any means bad, when the glands are removed.

III. What can be done to protect against the lymphatic glands? Every surgeon who deals with Carcinoma linguae knows that the glands are particularly liable to become cancerous even in a very early stage of the disease and my tables show how frequently, successful treatment of cancer of the tongue has been followed by secondary affection of the glands, which had appeared normal at the time of the operation.

Unhappily we cannot forget how soon the removal of the cancer of the tongue will be followed by secondary affection of the glands of the neck, and we have yet no means of discovering which cases of cancer of the tongue are likely to be associated with secondary cancer of the glands, unless there is enlargement of the glands at the time of operation on the tongue.

Looked at in its proper light, cancer of the tongue (Aqueous-celled carcinoma) is a malignant local disease so limited to the tongue and the neighbouring lymphatic glands of the neck that the prospect of dissemination of the disease may be diminished, since operation can deal so successfully with 70 per cent. of these cases that there is little fear of recurrence *in situ*, but of these 70 from 30 to 40 will probably die of affection of the glands of the neck against which there seems to be no 'rule of thumb' means of protection; because every case of cancer of the tongue has the glands of the neck already inoculated with cancer, and if the inoculation is successful, glandular disease will, as a rule, show itself within 8 months of the operation on the tongue.

Two alternatives suggest themselves. (1) the immediate and (2) the expectant; but both are fraught with singular difficulty and danger and considerable doubts. We might adopt (1) the first alternative by removing the lymphatic glands (whether obviously diseased or not) at the time of the operation on the tongue, but for the uncertainty on the all-important point of the group of glands which is likely to be affected in any individual case of cancer of the tongue. Sometimes the affected glands are half way down the neck, on a level with the thyroid cartilage, at other times behind the angle or the symphysis of the lower jaw, while at others again they may be in the floor of the mouth. so that no sufficiently regular rule seems to be observed to justify the extirpation of a particular group of glands in each case of cancer of the tongue, and the knowledge of these facts has deterred other surgeons, besides myself, from a routine removal of the glands in cases of carcinoma linguae.

The expectant method (2) is to remove the glands as soon as the slightest enlargement of them is apparent; but here we often meet with grave disappointment; as by the time the glandular enlargement becomes apparent to the patient or his medical attendant the affected glands are usually so fixed or so numerous, or both, that it is useless, and often dangerous, to attempt to remove them. The difficulty also of discovering the glands, through the structures that cover them, sufficiently early to

the patient was under the influence of the anæsthetic, and the operation was performed without any pain being felt, although they had been closely watched for when the patient was under the anæsthetic.

IV. In spite of this necessity I have become so convinced of the necessity of a radical operation for removal of the glands, if operative treatment of cancer of the tongue is to be more successful that I have carefully studied the subject during the last two years. The lymphatics of the tongue are so disposed that they may pass through one or more of four groups of glands: (1) the sub-mental group lying under the floor of the mouth behind the lower jaw; (2) the submaxillary, some of which actually lie in the substance of the salivary gland; (3) the parotid and (4) the carotid which lie over the course of the carotid and particularly over the bifurcation of the common carotid.

So far as the majority of cancers of the tongue are concerned—especially those that can be removed and are unlikely to recur in the mouth—it may be foretold that they will inoculate one or more of the three anterior groups of glands—the submaxillary and carotid groups particularly—and their removal ought to preserve the patient from glandular affection. With this in mind I have, during the last 18 or 24 months, removed all the contents of the great anterior triangle of the neck, including the submaxillary salivary gland. To do this, I make one seven-inch incision on the anterior border of the sternomastoid muscle from the mastoid process to below the thyroid cartilage and a second incision from the symphysis of the lower jaw to meet the first incision at about the upper level of the thyroid cartilage. Raising the two triangular flaps thus mapped out, I carry the dissection from the apex of the triangle below, upwards to expose a considerable portion of the large vessels which I clamp and then cut through, and the submaxillary salivary gland is removed. The connective tissue and glands are all carefully dissected out from the triangle and taken out in one continuous mass. The muscles in front are searched for one or two desperated lymphatic glands, which are removed with the glands in front of the parotid gland, those about the angle of the jaw, and the other contents of the triangle. The submental and parotid glands are not so easily and certainly removed *en masse* in this operation as are the submaxillary and carotid groups, which are readily removable. This dissection occupies from 60 to 75 minutes, but the wound heals so rapidly that the patient can go out of doors eight or ten days after the operation. The disease of the tongue should be first removed, and when the patient has had five or four weeks to recover from that operation and can take food well, the removal of the contents of the anterior triangle may be undertaken without fear.

The time has not yet arrived to speak definitely, but in the course of the next two or three years I hope to be able to judge of the results of this preventive method which I shall then publish. A more detailed account of the modes of performance of together with a note of the patients on whom it has been performed and of the fortune, good or

bad, of the operation, will be given in the next issue of the *British Medical Journal*. I have not space to say more of the operative treatment of cancer of the tongue, particularly when the disease is situated in the anterior two-thirds of the tongue, and above all when the operation is performed at an early period of the disease.

WHO ARE FRAUDS?

A FEW NOTES ON THE C. D. REGULATIONS.

By WM. HUNTLY, M.A., B.Sc., M.D.

Nottingham.

As another man styling himself "A Medical Man" joins in with a "Hater of Frauds," it may be well to set before your readers a few fresh notes on this subject.

"A Medical Man" begins badly. He says 79 medical ladies; the number noted in the *British Medical Journal* for 26th February 1896 is 73. It would hardly be worth while noting this, only that loose manipulation of figures is and has been characteristic of his party.

Then he writes, "some 8,000 cases of venereal disease are imported from India to England every year, and later on adds in opposition to the contention of the medical women that "soldiers" "are treated far more carefully than the same class in civil life; they spend long periods in hospital at the expense and to the loss of the State."

The natural inference from the above two statements is that in spite of professed long and careful treatment, 8,000 soldiers go home yearly, taking with them uncured venereal disease. I place no faith on the figures 8,000, but our medical friend will see that he is adding a fresh proof of the contention of these same medical women that it is nigh impossible to say when one is quite free from venereal, and, moreover, it has been shown over and over again by independent medical men and was demonstrated by myself some years ago in a paper in the *Record* written in opposition to the late Sir WILLIAM MOORE, that it is fatally true concerning venereal in women. If venereal can be thoroughly well treated in military hospitals, then it is a lasting stigma on army medical men that 8,000 are sent thus home. What more evidence does "Medical Man" want? Whoever said that we should not try to check venereal disease? What the opponents of the C. D. Acts ever is this, that we should no longer go on perpetrating a fraud, and a failure, and a thorough-going immoral practice.

"Medical Man" finds himself sadly put to it when he tries to criticise the statement that "it lies to a large extent within the power of the individual to avoid infection. With other contagious diseases there is not the same power of voluntary escape." The individual here alluded to is the "soldier," and the statement for him is absolutely true. "Medical Man" tries to throw dust in people's eyes, by alluding to women contracting it in the marriage relationship.

The man who stands up expecting to receive a pure woman and one free from venereal and who himself consciously conceals the fact that he has the disease is committing a big crime—and he knows it in his conscience. He expects cleanness while he knows he has only unclean-

ness to give in return. The party who consistently insisting this disease enters into the marriage relationship with one who has it, not and who knows not that the man is diseased, is a criminal in God's sight. The means of preventing this can never come from C. D. Acts, and that our "Medical Man" knowing, yet throws it before our readers as if C. D. Regulations would do away with this. It can only come by infusion of more honor and moral stamina in men, and for imparting that, I don't think even "Medical Man" would advise a course of the C. D. Acts.

Can venereal diseases be treated in the same way as other infectious diseases and treated successfully? Are the present Cantonment Rules framed to do so? Is it not true that when the authorities in India had far more power than they have now in this matter, or will have again in the future, *pleases God*, the Acts as confessed by themselves were a failure—a big medical failure, in spite of the quotation of two feeble French sentences by "Medical Man." "Medical Man" should study the yearly rise in venereal as shown by army figures, submitted by army men when regulations were in vogue.

Concerning venereal and other infectious diseases the following paragraphs may help "Medical Man" to see things in their right relations:—

"We quote the weighty words of Lord LISTER, who, speaking in the House of Lords, on 17th, May 1897, said: 'Such a disease [small-pox] and others enumerated carry upon their face the evidence of their existence by symptoms that any medical man can at once discern. But with venereal disease the case is totally different. In the early stages of the complaint, in which it is of the most essential consequence that it should be recognised—for efficient treatment depends upon early recognition—there is no general effect produced upon the system whatsoever. The person appears to all ordinary examination perfectly healthy, and it is only by special examination, which it is enacted shall not be compulsory, that evidence of the disease shall be obtained. How can any notice be given to the medical man that a person has such a disease? Who is to give the notice? I do not understand it. In truth it is the fact of prostitution, not evidence of the presence of venereal disease, on which the authorities must proceed.'—*Times*, 18th, May 1897.

"We should also refer to the memorial addressed to Lord GEORGE HAMILTON by the British Committee on 15th, April 1897, in relation to his despatch to the Indian Government.

"With regard to the placing of venereal diseases on the same footing as other contagious disorders in the manner proposed in your despatch, we respectfully submit that this is, in the nature of the case, impossible. In this relation we would direct your attention to the following considerations:—(1.) It casts no stigma on the name or character of a person to assert that he, or she, is affected with 'cholera, small-pox, diphtheria or typhoid fever,' and it can be ascertained whether such statement is true without shock to the feelings of the most refined. The opposite is the case with venereal disease, in regard to which a mis-statement is a virtual libel, and a compulsory examination is an adjacent outrage. (2.) As regards the former classes of disease, no conceivable measures can

have any moral bearing; whereas in the latter class compulsory (and in some of its relations, even voluntary) submission to examination or treatment has the gravest moral consequences, both to the individual and the community. (3.) The procedure under the Rules you propose is as follows:—The Medical Officer is informed by a soldier that a certain woman is diseased. Believing that, he orders her for examination at the hospital. She may be perfectly honorable or perfectly healthy. In either case, if she refuses to attend, she is held to be diseased and is expelled from the cantonment. We submit that the whole of this procedure, though it may be in words the same as in a case of cholera, is in fact utterly different in the means by which information is secured, in the nature of the evidence as to fact, and in the consequences to the woman who disputes the fact. The operation of the Rules, so far as venereal disease is concerned, is not general. In the Report of the Special Indian Commission, appointed in 1893 by the Government of India to enquire into the working of the regulations, it is stated that, so far as venereal disease is concerned, the operation of the Rules is 'practically confined by sheer force of circumstances to women who are frequented by British soldiers. Even with regard to them information is difficult to obtain, for a man often does not know, and still oftener will not tell, which woman has diseased him.' And the same Report further says: 'Except in the not infrequent cases where a woman herself applies for medical aid, this (i.e., information necessary to proceed upon) can only be obtained from men who have been diseased by them.' It is clear then that a man, as the result of an admittedly immoral act, becomes an informer, and in many cases a false informer, upon whose testimony the State has to rely for submitting the woman to the most degrading process. We submit that there is no parallel between venereal disease and cholera, either in the procedure here indicated, or in the effect of that procedure on moral conduct, or in the position in which it places the State."

"It will be seen that the above quotation refers to the procedure under the Cantonments Act in India. But it will be observed that the same sort of difficulty must arise under the proposed scheme. For instance, take the clause in that scheme, 'Health authority to have the power to communicate with the patient. . . . We ask who is the patient? It is clearly here a person suffering from venereal disease who refuses to report the fact. How is the fact of his or her suffering from it to be ascertained? It can only be by the information supplied by the person who has been infected, or by the assumption that prostitution is itself an adequate evidence of disease. In the former case we have the evils described in the above quotation, in the latter case we have practically the re-establishment of the Contagious Diseases Acts in the periodical examination of prostitutes, whether diseased or not, in the determination of whether a woman is a prostitute or not, and in the segregation of a class of women subject to compulsory examination.

"The inclusion of men in such a scheme does not get rid of or in any way mitigate any of the above objections.

"Nor, indeed, is the inclusion of men practically possible. Lord LISTER, in his speech in the House of Lords above

quoted, said: "Beside with the men in the civil population the same there is an absolute impossibility."

It is with little hope however of convincing "Medical Man" and a "Hater of Frauds" that these notes are penned.

It is true that with a free hand for many years Regulation failed to stem disease and on the contrary promoted vice.

It is true that army medical men in India concealed the fact that from '89 to '92 in spite of a Resolution against these Regulations, they were carried out.

It is true that on the increase during these years when the rules were in force they tried to bring in a case against those who were opposed to Regulations.

It is true that they climbed down, beginning with Lord ROBERTS,—only when exposure of their ways compelled them to. What fine courage the A. M. S. has shown all along? It is true that the examination of women at the examination of only one of the units necessary to acquiring this disease is a fraud.

It is true that the examination of both parties sanitarily is a thing impossible to be carried out, and that any such attempt would defeat its own end.

It is true that in those countries such as Russia, where Regulation has been even more thoroughly carried out than by England, venereal literally floods the country. Do not medical men go to Regulation countries to study venereal diseases? It will be seen to be true that only moral means aiming to bringing men out of this filth will ever help to stop venereal.

It is true that Regulations encourage immoral tendencies and lead young soldiers into sin by fraudulent misrepresentation.

It is true that those who have from time to time framed these regulations have done practically nothing to raise the moral tone of the army.

But why go on. "Medical Man" says it is an unwelcome sign of the times that these women should have thus come forward. He again here utters truth. It must be an unwelcome sight to those who making a pretence of adopting moral measures and professing themselves zealous to raise the moral tone of the army are steering straight for the introduction of immoral regulations, a cowardly and immoral course. The devil airing his theories as righteous and good. The rake holding his head up and saying, "I am the man whom the Government delights to honor." Small wonder that in answering one of the questions submitted to soldiers for answer in the *Indian Medical Record* of 1st February, a soldier wrote.—"The libertine is preferred." Was KIRLING thinking of an A. M. S. man, when he draws "TOMLINSON"? "Medical Man" also writes of the "unscrupulous manner" in which light on the subject of prostitution is disseminated "amongst women of all classes and even amongst unmarried girls." One wonders what type of a man "Medical Man" is, who thinks it bad for the women of England to know what is going on in India and to know of the results of immoral intercourse. Has he any daughters himself? Because women and girls and Doctors have their eyes opened to the unscrupulous conduct of unscrupulous men,

this modest essay shows that it is indeed an evil day for men with such ideas as to decency, and the more evil such men think it, the greater will be our cause of rejoicing.

No sir, the importance of the memorial does not arise from the fact that behind it is arrayed what Mr. RHODES would call the unctuous self-righteousness of England, but because behind it is the great God himself. We think the unctuous righteousness is on the other side, or shall we call their plans, unctuous immorality? Pray who are those that "could gauge this memorial at its proper value."—not Parliament or the Secretary of State? I suppose "Medical Man" and "Hater of Frauds" and the Indian authorities who have as concerning the Regulations been acting a dishonest and fraudulent part all along, would be the right party. We should like these men to have shown a cleaner and honest record in the past. We don't need a French phrase to settle the question. The question has been settled long ago by the very figures and the Commission appointed to examine those figures. Failure and deceit are writ large in this matter. Or are we to send memorials to such as are represented by Colonel WYNNE who acts as spokesman for all scoundrels and rakes when he says, "sexual vice never has and never will be considered disgraceful in men—at least, by the great majority of men, and I may add of women also." It says very little indeed for the type of women in Colonel WYNNE's social circle, if this be his experience. The sex question is a root one. And if such a statement be at the root of the boasted civilization we are supposed to be giving to other races, it is a pitiable, immoral, fraudulent thing, filled with rottenness.

It is not venereal disease which will ruin our nation, but the vice which is propagated and the sea of impurity which is set free by the vicious and immoral tenets of such as "Medical Men," WYNNE, DASHWOOD, and others of the impurity party. A vicious nation can never be a strong one, for God must ever be opposed to vice.

COLD IN THE ETIOLOGY OF DISEASES.

CHELMONSKI, in the *Deutsches Archiv, für klinische Medicine*, 1897, p. 140, reaches the following conclusions:—

1. Taking cold, in the ordinary acceptation of the term, does not exist.
2. The etiological role of cold is very subordinate; in inflammatory affections it does not figure, except as a predisposing cause.
3. Chilling is dependent upon the action of thermic agents that are ordinarily difficult to avoid.
4. The mode of reaction of the skin against the thermic excitation produced indicates whether the individual may, in certain conditions, contract a cold.
5. The degree of tendency to colds is not a constant property of the individual.
6. Old persons, those attacked with intermittent fever, and individuals suffering from renal affections seem to be more subject to taking cold.
7. There does not exist any relation between the tendency to colds on the one hand, and the condition of nutrition and the thermic sensibility on the other.
8. Individuals may be protected from diseases caused by cold by developing, with appropriate means, the power of reaction against the thermic influences.—*Clin. Jour.*

A MINOR OF PRACTICE

UNINTELLIGENT VERSUS INTELLIGENT MID- WIFERY NOTES OF A CASE.

By ERIC A. HOWAR, M.D.

Sind.

NATIVE DEANS have obtained for themselves such a bad name for prejudice against enlightened obstetrical surgery, at least until too late for it to have a chance of success, that it gives me real pleasure to be able to tell a different tale.

On a recent Sunday morning, I was requested by a native servant to come and see a woman of his family who had been two days in labor. She led me to a very neat and clean little servant's godown in a sahib's compound—highly decorated, indeed, "I may say—where the patient was lying on a dement bed, with two women in attendance, viz., her sister and an intelligent little *dhai* from whom I learnt that the patient had had pains for eight days, and for two days severe with no rest at night, and that sometimes a hand, sometimes a hand and foot, sometimes two feet, were presenting. The pains were irregular, and by no means strong; and examination showed me the membranes intact, the os soft and distensible but not fully dilated, and both feet presenting, the head being plainly to be felt in the right flank, and the heart sounds faintly audible in the immediate neighbourhood of the umbilicus and the fetus evidently a very small one. It transpired that a family council had been held over the protracted labor, at which the calling in of another *dhai* and the removal of the patient to hospital had been discussed, but the *dhai* had objected to "any more black *dhais*," and the husband had negatived the hospital alternative, and so they had decided to ask whether I would come and see the case.

The choice of treatment plainly lay between seizing the feet and so easily securing a longitudinal presentation by the breech; and an attempt at external cephalic version, with risk of accidental rupture of the membranes during the process and so of losing the good chance of the feet without gaining the head. The membranes, however, seemed so strong and the pains so mild and infrequent, that the latter plan appeared to me justifiable. After working away for some time at external manipulation, the *dhai* evidently entering into the spirit of the enterprise and giving me intelligent assistance, and when to external appearance some ground had been gained, I again examined internally and found the feet still there (though a little more to the left), and no sign of the head. It was clearly a dorso-posterior position with a very small and flexible child, offering therefore comparatively slight purchase on the large parts of the fetus; so I then determined to change tactics and resort to podalic version as more simple under the circumstances. Without administering chloroform, I introduced my hand to secure the feet, and in so doing encountered the head, above the sacral promontory to the back of the uterus, and succeeded in bringing it to the brim of the pelvis. In endeavoring to rupture the membranes in order to ensure the engagement of the head, I found them so tough that it was impossible to rupture them with the finger, and it was necessary to

pinch them with the wire snuffers of my obstetrical set. (For *dhais*' sake I am omitting all description of the obstetric precautions offered; but they are to be understood.) The pains now became irregular and frequent; and the os being distensible and the fetus small, I handed the case back to the *dhai*, anticipating an early spontaneous termination.

But progress was very slow, and I soon had to resume the conduct of the case. The artificial rupture of the membranes having converted the labor into a "dry" one, the remaining dilatation of the os proceeded very slowly and a swollen anterior lip soon developed, forming an obstacle which the pains were not forcible enough to overcome, even when aided by gentle digital pressure from below. There was at no time any indication for instrumental interference, nor the remotest prospect of any such arising; but the patient was greatly fatigued, and both she and her friends were evidently disappointed at the delay after the error of presentation had been corrected. So, after a couple of hours had passed with little or no advance of the head and but slight change in the condition of the os, I resolved to re-inforce the pains with a dose of liquid extract of ergot *Mvii*, repeated after half an hour, when the result proved insufficient; and in due time a couple of strong pains expelled the child (which was living and cried promptly) and immediately afterwards the placenta. The uterus retracted firmly at once, there was no hemorrhage, and the patient made a good recovery.

NOTES ON AN INTERESTING CASE OF NASO- PHARYNGEAL POLYPUS, SUCCESSFULLY REMOVED.

By SURGEON-LIEUT.-COL. W. H. HENDERSON F.R.C.S.I.

Civil Surgeon, Hyderabad, Sind.

PATIENT named SIDIK, aged 19 years, was admitted into the hospital on 10th February 1898, for a large growth in the right nostril extending to the mouth.

Condition.—Patient very anæmic. Pulse weak and intermittent. Breathing very labored; the right half of the nose completely blocked by the growth, which was about the size of an orange. On examination, the growth was found to be protruding through the right nostril and backwards through the right posterior nares occluding both the nares to such an extent as to be seriously interfering with the respiration, occupying the superior aspect of the pharynx and pushing the soft palate downwards and forwards. On digital examination, the tumour was found to be soft to the feel in front, but hard and ulcerated posteriorly.

11th February 1898—The operation.—It was resolved to remove as much of the growth as was possible. The patient having been brought under the influence of chloroform an incision was made in the right side of the nose commencing a little below and outside the inner canthus, and terminating in the median line of the upper lip. The detached portion, being reflected to the other side, the nasal portion of the tumour was fully exposed, but as there was not sufficient room for the removal of the whole, as much of it as was possible was snipped off. The pharyngeal portion was then

laid open by incising the soft palate in the median line. It was then drawn forward by passing a silk ligature through it, and as much of it also as was possible was removed by scissors. The remaining portion of the tumour (i.e., the central) which could not be reached, either through the nostril or mouth, had to be left untouched, as further operative interference was deemed unsafe, as the patient had already been long enough under the influence of chloroform.

3rd May 1898.—As the patient had evidently lost a considerable quantity of blood during the last operation, he was put on a course of iron treatment, and the character of the pulse was carefully watched, and though he seemed greatly improved, the intermittency of the pulse remained unaffected. During the interval, however, the tumour grew rapidly, showing itself through the nostril and mouth. Further operative interference was therefore deemed necessary, and it was this time resolved (i) either to expose and remove the growth by performing an osteoplastic section of the superior maxilla, after preliminary tracheotomy (ii) or to lay open the anterior nares, by incising the upper lip in the median line, carrying it from the ala of the nose upwards, a little away from the median line, with an osteoplastic section of the nasal bone, if necessary.

Having regard to the intermittency of the pulse and general delicate state of the patient, it was decided to attack the tumour by the latter and less extensive operation. The amount of space obtained by incising the parts up to the nasal bone having proved to be quite sufficient for handling the tumour on all sides, feeling its attachments and snipping it off with scissors, further extension of the incision involving the osteoplastic section of the nasal bone was dispensed with.

Remarks.—It was during the course of this operation that the tumour was found to be firmly attached to all the osseous surfaces, surrounding the posterior nares, viz., the basilar process of the occipital bone and inferior surface of the sphenoid bone, posterior part of the hard palate, below the pterygoid process on the outer side of the vomer on the inner side. Extensive as the attachments were, they could be reached and dealt with all round with ease. The results were so satisfactory, and the space obtained so considerable owing to the pliancy and dilatibility of the soft parts, that it is surprising how so little mention of it is made in the standard works on the subject. The operation is altogether so devoid of danger that, it is hoped, an extensive trial will be given to it.

AN INTERESTING CASE OF PULMONARY ABSCESS, TREATED AS LIVER ABSCESS BURSTING INTO THE LUNG.

By R. G. KAR, L.B.C.P. & S. Edin.

Physician to the Calcutta Medical School Hospital.

Reported by BENI MADHAV BASU, C.M.S.C.

House Surgeon to the Hospital.

KESHIBOR COOMER NATH, of Bhowanipur, aged 40 years, was admitted to the hospital on the 11th November last, suffering from hepatic disturbance. Stated that this was his third attack, the first having occurred a year previously had lasted two months, the second attack lasted a shorter

period, whilst the third and present one had started five months ago.

Symptoms.—Pain over the shoulder and liver, tenderness over the hepatic region, jaundice and constipation. He had been to the Medical College Hospital, where he had been treated for liver abscess, after which he was admitted into the South Suburban Hospital, Bhowanipur, where he had been treated for two months on the same line. General appearance slightly anæmic, skin rough and dry, fever every evening preceded by a feeling of chilliness.

Cough very troublesome, sputum rusty colored. Respiratory murmur a little louder on the right side, also vocal resonance slightly increased, percussion sound slightly dull on the same side. Heart sounds normal. Liver increased upwards to the nipple in front and angle of the scapula behind. A spot about $\frac{1}{2}$ inch below the nipple and $\frac{1}{4}$ inch externally was very tender to the touch. Spleen normal.

Dr. R. G. KAR prescribed the following on the 11th November 1897:—

R. Ol. Eucalyptus	3ii.
Ol. Turpentine	3i
Acid Carbolic	3ss.

For inhalation on cotton wool.

R. Lint. Iodin.	3ii.
Lint. Belladonnae	3v.

To paint over the painful hepatic region.

R. Tinct. Camphor Co.	℞. x
Ammon Chlorid	gr. x
Tinct. Cinchona Co.	3ss.
Pot. Bicarb	gr. x
Ol. Copaiba	℞j.
Mucilag. Acacia	gr.
Aqua	ad 3i

Four times a day.

The range of temperature from 11th to 17th November was 101°2F. in the morning to 102°6F. in the evening.

From the 17th to the 29th November patient improved. No rise of temperature, but the cough was very troublesome; for this he was given

R. Liq. Morphine Hyd.	℞. list.
Pulv. Acacia	q. s.
Mel	3ss.

To be given as linctus every three hours.

The fever rose up to 102°F. from the middle of December. On the 21st it was 105°6F. Pain over the chest and hepatic region increased.

The temperature now kept normal and the pain over the chest and hepatic region subsided. The temperature again rose to 102° in the beginning of February, cough very troublesome, brought up bloody pus in great quantities with the sputum, could not digest anything.

R. Tinct. Hamamelis	℞. vi.
Ext. Ergot Liq	℞. x.
Sodi Sulph.	gr. vi.
Liq. Morphini	℞. x.
Tinct. Eucalypti	℞. viii.
Aqua Chloroform	...	ad...	3i.

Four times a day.

Sodi Benzoat	grs. vi.
Salol	grs. v.
Quinin Sulph.	grs. iv.
Ethonymin	grs. i.

Three times a day. To aid digestion and subdue fever.

In the beginning of March 1898, the condition of the patient continued the same but the spitting of blood had diminished. The cough was very troublesome. Temperature rose up to 102°F. and 103°F. All medicines were changed to the following:—

R Guaiacol Carb	grs. v.
Twice a day.			
R Sodi Benzoat	grs. v.
Salol	grs. v.
Quinin Sulph.	grs. iv.

Twice a day.

R Liq. Arsenicalis	m.iii.
Via. Ferri	℥.xx.
Tinct. Gentianæ	3ss.
Aqua	...	ad...	3i.

Twice a day after food.

3rd April 1898.—Fever rose up to 103°F. and 104°F. Dyspnea was more marked. Could not lie in recumbent position.

On inspection, it was found that the right side was slightly bulged. On percussion, the right side of the chest was of wooden-dullness, but slight resistance was felt at the time of percussion. On auscultation not the slightest breath sound was heard on the right side, but the heart sound was conducted on that side. At that time Dr. KAR suspected empyema. He then introduced a hypodermic needle within the pleural cavity when pus came out. He then aspirated in the 5th intercostal space and a quantity of pus escaped. A rubber drainage tube was put through the cannula and the other end of the tube in a corked bottle, but the pus was too thick to come out.

6th April.—Parietothoracotomy was performed. and a large quantity of pus came out. Dressing was changed every two hours.

Large quantities of pus escaped daily. The patient's vitality was fearfully lowered, and he succumbed on the 14th April.

Post-mortem.—It was found that the pleura covering the right lung was thickened about $\frac{1}{2}$ of an inch and adherent to the chest wall. The whole of the right lung was a big cavity, except at the apex. The cavity was simply covered by a thin layer of lung tissue and was full of thick pus.

Pleura was not adherent to the diaphragm

Liver was enlarged, specially the left lobe.

Left part of great omentum was adherent to the abdominal wall.

No fluid in the peritoneal cavity but fluid was found within the subcutaneous tissue.

Mitral valves were slightly thickened.

Remarks.—This case had been diagnosed in the Medical College Hospital and South Suburban Hospital and Calcutta Medical School Hospital as liver abscess bursting into the lung, all the symptoms were in favor of that disease, but at the post-mortem it was found to be a big abscess of the lung.

Indian Medical Record.

1st June 1898.

THE CALCUTTA CORPORATION AND ITS CROMWELL.

WHEN a representative body, whose main province is to act, becomes transformed into a mere talking machine, when important and urgent measures are merely looked upon as opportunities for chopping logic, when useless discussions follow on each other's heels without producing any result, when in fact the time of the representatives is wasted and the interests of those they represent neglected, and when all this waste and neglect means loss of money, loss of health and loss of life, it is quite time that a CROMWELL should appear and in solemn tones warn such a body to amend its ways.

Sir A. MACKENZIE has played the part of CROMWELL to the Calcutta Corporation; in our last number we discussed some of the clauses of the new Act which is to come into force on the 1st of April 1899. We will now turn our attention to the reasons which have been put forward to justify its introduction, and we will briefly consider the present constitution of the Municipality, its methods of procedure, and the sanitary condition of Calcutta under its auspices.

AN UNWORKABLE CONSTITUTION.

We learn from the letter addressed by the Bengal Government to the Government of India, dated 7th March 1898, that under the present law there is no Municipal constitution at all in the proper sense of the word. The Act vests in the Commissioners all powers, but it allows the Chairman to exercise all the powers vested in the Commissioners (with a few exceptions). But the Commissioners have the power to limit or alter any action the Chairman may take, or even has taken under this power. It further confers an unlimited power of controlling the Chairman by the action of Committees. By thus failing clearly to define the powers of the executive, the Act renders it impossible to say as regards any given matter in what part of the Corporation the executive resides, or indeed whether there is any executive at all, and the Chairman appears to be reduced to a cypher.

Sir HENRY HARRISON remarked in the Bengal Council on 4th February 1888:—

"The rôle which the elective Commissioners for the native wards have at once assumed is precisely that of checking, watching and controlling in every way, in seeing either that no expenditure is incurred without sufficient reason, or that projects of improvement are not undertaken which cannot be fully justified. They have in fact been the brake power in the municipal train. But a train cannot progress by brake-power alone, nor can a city thrive by opposition alone.

UNWORKABLE COMMITTEES.

Since Sir HENRY HARRISON's time the power of the Chairman has, it appears to the Lieutenant-Governor, been gradually dwindling and the interference of the "Committees" has been rapidly growing. The "brake-power" has been increasing, and the "brake-power"

becoming a standing order. Under section 55 of the Act, the General Committee, which deals with Budget and Finance and other business as may be referred to it by the Commission or does not fall within the sphere of any other Committee. When the Chairman and the majority of the General Committee dissent, and inconvenience is likely to arise from delay, action can be taken in anticipation of the confirmation of a General Meeting, but not otherwise. Under section 55 the Commissioners may appoint any other Committees either standing or special, and consisting of so many members as they may think fit for the purpose of enquiring into and reporting upon any matter connected with the conservancy or improvement of Calcutta, etc. Besides two special Committees, one of 14 members, to deal with the question of the amalgamation of the Roads and Conservancy Departments, and a Boundary Committee of 17 members, there were in 1895-96—

- (1) the Bye-laws Committee with 9 members ;
 - (2) the Loans Committee with 9 members ;
 - (3) the Hackney Carriage Committee with 6 members.
- These subjects do not apparently interest the Commissioners greatly, and the Committees were comparatively small ; but as we go on we find—
- (4) the Water-supply Extension Committee with 31 members ;
 - (5) the Busti and Town Improvement Committee with 38 members ;
 - (6) the Suburban Improvement Committee with 21 members ;
 - (7) the Roads, Buildings, Conservancy and Tramways Committee with 48 members ;
 - (8) the Complaints Committee with 33 members.

The Chairman and the majority of a Committee, if in accord, have the same power as the General Committee of anticipating the action of a general meeting.

Exception is taken to the number of Committees, especially to the Complaints Committee, which was held to have been a mistake from the beginning and which is said to take two months to dispose of a single complaint, though complaints come in at the rate of twenty a day.

Many of the Committees are obviously too large for effective work, but in 1896 a change was made in the wrong direction by allowing any number who liked to serve in any Committee, so that they swelled and became dropical beyond the power of action.

AN INEFFECTIVE EXECUTIVE.

The Chairman and Executive, it is stated, have far less power than they ought to have, and it may almost be said that there are as many Chairmen as there are members of Committee. Thus questions that under any reasonable system would be settled by the Executive, are submitted to the Committees, for consideration and orders, the Executive evidently finding it useless to move without previous sanction. Even if orders are issued by the Executive under the Act, they are not infrequently brought before one or other of the Committees for revision. A common procedure is that a Sub-Committee is appointed to enquire and report (i.e., to do over again the work of the Executive, whose reports apparently command com-

parative little respect). Work is perpetually suspended. The Sub-Committee may report in course of time, or it may "lose the paper." Sometimes it keeps the matter pending for months or even years. A more effective device for hampering promptness of executive action could not be invented.

Again, it frequently happens that when the Executive, i.e., the Engineering Department, refused sanction to construction as opposed to the Building Regulations, the aggrieved parties got the matter put before the Building Committee and the Executive reversed.

BUILDING REGULATIONS.

Discussing these Regulations in 1895, Mr. M. N. Ghose said :—"From a common-sense view the law and the bye-laws seemed good enough ; but sometimes the ingenuity of lawyers and sometimes the Commissioners themselves who had cases to support had made the rules unworkable. In many cases when they were absolutely plain and unambiguous, they had been twisted so as to make them inoperative and futile."

Babu KALLYNATH MITTER "maintained that the bye-laws had been violated on the most flagrant manner possible."

Within the Corporation itself they were many who were quite alive to all these shortcomings ; regarding Busti improvements, Babu R. C. PAUL, said :—"Busti improvement was one of the greatest necessities of the town ; but it was now practically at a standstill. There were many bustis in the Northern Division of the town which were in the same state now as they were ten years ago." "It was a long-standing complaint that the working of the Conservancy Department was going from bad to worse."

And Babu N. N. SEN expressed the same opinion. But there is no use multiplying instances of the most wanton dilatoriness and delay ; there is no denying that all this is a strong indictment of the way in which the Municipal affairs of Calcutta have been managed, and proof that the time had come for some improvement in the system of Municipal government.

REPRESENTATION OF THE CORPORATION.

We read that the Hindus alone outnumber all other nationalities in the Corporation. In 1876 a Select Committee was formed to consider the proportional representation of the city, its proposals were, however, not well received, and were rejected in deference to the views of Babu KRISHN DAS PAUL, who urged that the system of proportional representation would be isolatic and would prevent Hindus from electing Europeans as their representatives. "It might be said that the larger number of rate-payers being Hindus, they would flood or swamp the Corporation ; that was to say, the majority of persons elected would probably be Hindus, and that other sections of the community would be over-riden. He did not think that that would be the case. For his own part he thought that the Hindus were well aware that they had to learn a good deal from Europeans, and that in the matter of Municipal management they by themselves could not do much. United with Europeans, they could do a great deal, but single-headed the Hindus were too weak. So he did not believe that the result would be in the direction apprehended."

Whether Babu KRISTO DAS PAUL made this suggestion in good faith and sober earnest we know not, but there is something in it so delightfully ingenuous, so strongly reminiscent of the simplicity of the "Heathen Chinee," that we are almost inclined to think that the learned gentleman must have "winked the other eye!"

At any rate his prognostication was not realised, and the "Mild Hindu" continued his preference for his compatriots.

The results of the working of the present Municipal law in Calcutta may, we read, be summed up as follows :—

(1) The conserrancy of the town has been shown to have broken down in material points ;

(2) the collection of the rates has for a long time been defective, and about two lakhs of revenue have yearly been written off as irrecoverable ;

(3) important branches of the accounts have fallen into confusion ;

(4) the uncertainty as to the respective functions of the Chairman and the Corporation has paralysed the action of the executive ;

(5) the European commercial community is inadequately represented and does not exercise the influence to which it is entitled.

Certainly a grave and disgraceful state of affairs for the leading city in India.

INSANITARY STATE OF CALCUTTA.

We will turn to the Health Officer's Report for 1896 for a few side views on this subject. From what follows it will be seen that he had some reason for thinking that the appointment of the Building Commission would be the announcement of a new era in the sanitation of Calcutta, that some of the Commissioners did not agree with him we can readily attribute to their knowledge, guilty or otherwise, of the means by which the best rules and regulations can be misused and rendered null and void.

Talking of over-crowded areas he says :—"The condition of the worst of these areas is indescribable. Ocular demonstration alone conveys to the mind a state of affairs that words fail to depict. Every one, I have taken over the area bounded by Rutton Sircar's Garden Street on the north, Canning Street on the south, Chitpur Road on the east and Olive Street and Durmahatta Street on the west, is unanimous in condemning it as unfit for human habitation and a source of danger to the town. The whole area is intersected by narrow lanes and passages ranging from 6 to 20 feet in width. Only one broad road, the Harrison Road, and that recently constructed, passes through it from east to west. The houses facing these narrow streets are two, three and four stories high, and are often separated from one another by passages two and three feet wide. In these narrow passages, in such situations, as often to be almost inaccessible, are the latrines of the houses which in many cases are merely compartments with openings in the floor communicating with a long shaft leading to a dark and ill-ventilated privy-vault where the secrets have, in consequence of their long descent, splashed in every direction, and formed a cess-pool which it is impossible to clean properly. To connect some of the latrines with the

sewerage system only gives rise to conditions equally as bad, because they are used and badly used by a large number of the people, most taking the place of soap for ablutatory purposes. Under these circumstances, unless there is an unlimited supply of water, and in fact even then, the pipes and taps become choked and overflow. The houses are chiefly occupied by Marwaries whose habits are such that all refuse is thrown, from whatever part of the house they occupy, into the court-yard in the centre of the house or into the passages between the houses, some of which are so narrow as to suspend in mid-air kerosene tins or similar articles which may be thrown from the upper stories. The narrow ill-ventilated streets, the passages to which neither light nor fresh air have access, the filthy condition of both, the close proximity of the houses to one another and their over-crowded state combine to form conditions which render proper sanitation impossible."

A MODEL NATIVE HOUSE.

The following is an example of what a builder will construct if uncontrolled :—

77, Cross Street.—A four-storied *pucca* house approached by a narrow passage and divided into two parts and so surrounded by houses that it has no through ventilation whatever. The court-yard of the inner building measures 66 feet long and is 5 feet broad ; over it is a bridge 7 feet wide connecting the two ranges of stories separated by the 5 feet wide court-yard. Viewed from above the court-yard is a long narrow well and at the bottom which corresponds to the ground-floor are 19 apartments each measuring about 12 feet x 6 feet x 10 feet, and occupied on an average by 4 persons, being less than 200 cubic feet per person. The rooms are pitch-dark, and until the eye becomes accustomed to the want of light, it is impossible to see the occupants of the rooms without artificial light. There is no ventilation except by the door opening into the court-yard. Latrines are dark, unventilated and without flushing arrangements. The rooms facing the court-yard on the higher stories become lighter as the top is approached, but none have any through ventilation. The other court-yard measures 21 feet by 7 feet, and the rooms are in somewhat similar condition to those described above. An application has been made to have this house closed as uninhabitable.

For further details of this unsavoury description we turn to Dr. BANK'S Reports from October 1896 to March 1897, and his evidence before the Medical Board, and the following are some of the facts which come to notice :—

OVERCROWDING.

Overcrowding.—There was great overcrowding in Wards 2, 5, 6, 7 and 8, where houses of two, three and four stories were inhabited by monthly tenants who are shop keepers, hawkers, brokers and occasionally pilgrims. The houses were separated by narrow lanes or passages into which all refuse was thrown, and drop privies discharged their contents. One such lane separating two-storied houses in Ward No. 5, 60 feet long by 1½ feet wide, was found closed at both ends and containing a mass of refuse 9 feet high. In another case, a similar lane between three-storied houses, measuring 100 feet by

1 foot 4 inches, was closed at one end by a privy and at the other by a pukka wall, and was filled with house-refuse, night-soil and other filth. In a third the passage was only nine inches wide, and no mehter could get access to the privy.

FILTH IN EXCHLUSE.

Private privies.—The ordinary private privy consists, according to Dr. BANKS, of a hole in the floor, about 9 inches in diameter, with a seat about the height of a brick. In the case of ground-floor rooms the night-soil drops usually about three or four feet without any conducting pipe into a vault below, where it is received either in a porous earthenware *gumla* or in a hole in the floor of the vault, from which it is baled out by the mehter. In the case of privies on upper floors there is sometimes a conducting pipe of masonry or Baniganj pottery into the vault, but as often as not there is no pipe. In order to clean these privies the mehters have to crawl on their hands and knees, or even to lie down, in order to get at the *gumlas*, some of which are so large that they cannot be moved, and are never properly cleaned. The vaults are usually quite dark. Ninety per cent. of the urine soaks into the floor or gets into surface-drains. The number of private privies was stated to be 60,970, of which 22,830 are *pucra* of the type described above, and 32,990 *kutcha* with seats and vaults of masonry, walls of bamboos or mats, and roofs of tiles or corrugated iron. Only 5,142 are connected with the sewers and have flushing arrangements. Connected privies were never cleaned except when the connection was reported to be choked. From one such privy in Harrison Road, serving a house occupied by 90 persons, 14 tons of night-soil were removed by the extra staff. Another in Burtola Street was full of night-soil and choked by 50 old shoes. Many similar instances were found. There were 1,996 mehters for unconnected privies, each of whom had on an average to look after 232 privies.

Such conditions as those would be a disgrace to any city in the world, how much more so then to one which adopts to itself the grand title of City of Palaces; it is to be hoped that the light which recent events have served to throw upon these matters may lead to steps being taken by those immediately responsible to prevent a recurrence of such scandals, and we sincerely hope that CROMWELL's second visit, the result of which we need not recall to our readers, may never be needed.

SUNSTROKE AN INFECTIOUS DISEASE.

WHEN a writer introduces an idea not only novel and startling but also subversive of what has been universally taught and accepted for ages, the least that we have a right to expect of him is that he should give us sufficient and reasonable grounds for the attitude he takes up.

We cannot find that this condition has been carried out by Dr. L. WESTERNDA SAMBON, in a paper contributed by him to the *British Medical Journal*, 19th March 1898, under the following title: "Remarks on the Etiology of Sunstroke (*Siriasis*). Not Heat Fever but an infectious disease."

He introduces the subject by setting forth that syncope and sunstroke are not the same disease. He says it is surprising that syncope should have been confounded with sunstroke, and we think so too, but we were under the impression that Indian writers had sufficiently differentiated between them.

Sunstroke or "*Siriasis*," as he prefers to call it, he defines thus, "an acute disease characterized by hyperpyrexia, profound coma and intense pulmonary congestion. Its mortality is exceedingly high. It has a peculiar geographical distribution; it prevails in the hot season, and occasionally in an epidemic form."

He proceeds to show that the authors who support the generally accepted theory are not agreed as to the exact manner in which the symptoms are brought about, and that there is much difference of opinion as to the true pathology.

True, but it is a well-known fact that we are very ignorant of the effects on the body of long continued exposure to heat. This ignorance is freely admitted in most works upon physiology and hygiene, but while it is to be deplored, it surely cannot be accepted as any proof of the correctness of Dr. SAMBON's hypothesis.

The fact that we are ignorant of the exact effects of prolonged exposure to heat on the organism, is no proof that heat has no effect at all.

When he says that the explanations offered, "are all based on the preconceived idea that heat is the sole efficient cause of the disease," he is not only wrong but he contradicts himself, for in another place he says: "The belief that heat alone could not account for *Siriasis* has often been expressed," and he admits that the oldest Anglo-Indian surgeons mention as causes of *Siriasis* "sun or heat and something more."

This being so, the examples he brings forward to show that the body can sustain great heat in ovens, in mines and bakeries without *siriasis* ensuing is totally irrelevant.

He mentions that CHABERT, the "Fire King," was in the habit of entering an oven the temperature of which was from 400° to 600°F; this has a coincidental interest for us, for in the portion of this number dealing with the "Life and Times of THOMAS WAKLEY" we show how WAKLEY exposed this very CHABERT who was nothing more than a clever impostor.

He mentions also that Chinese, Andamanese, and Negroes expose themselves with bare and even shaven heads to the sun with impunity, but to argue from this that the sun cannot produce the disease called sunstroke in a European, is about as convincing as to argue that because the heat of the plains of India does not disagree with a Bengal Tiger it would therefore have no effect upon a Polar Bear.

He also tries to make out that Europeans expose themselves to the greatest heat of the sun without suffering ill effects, and cites the Assam tea planters and Europeans in Arizona and South Colorado. This is no argument at all; for Europeans in India, at least, never expose themselves to the sun; on the contrary, they protect themselves from it by every means in their power. The fact of being able to go out in the sun is no proof of exposure to it. What are solar topsies and umbrellas for?

Again we are told that in many fevers the body temperature is very high, and yet *sirosis* does not supervene, but what this has to do with sunstroke we do not know.

Dr. SAMMON says "that the high temperature of *sirosis* and other fevers is not due to retention of heat is proved by the fact that under no condition is the mechanism of heat dissipation so wonderfully active as in "fever." Even supposing this to be so, the amount of heat dissipated must depend in a very large measure on the condition of heat and moisture of the surrounding atmosphere.

"Fever, he says, is the symptom common to all infections," and he suggests that it is a means of defence against micro-parasitic assailants.

To push what is here vaguely outlined to its logical conclusion would simplify pathology and etiology very much: thus the thermometer would tell us there was fever, fever is the symptom common to all infections, "we know that such symptoms are due to the toxins produced by micro-organisms," therefore there must be a micro-organism.

If all this were generally admitted, the author need not have written a line of his paper, for the fact of there being fever would alone be sufficient proof of the existence of a micro-organism and the existence of an infectious disease.

But if it is not universally admitted, in fact if it on the contrary be very much doubted, what value can possibly be assigned to it in the case of sunstroke?

"The symptoms of the disease," we read, "its relapses, its morbid anatomy, its peculiar geographical distribution, its epidemic outbursts, the conditions of climate and soil under which it prevails, the relative immunity to its attacks afforded by acclimatization, all clearly point to the specific infectious nature of the disease."

We are much disappointed with the meagreness and unconvincing nature of the remarks our author has to make under each of these headings.

Regarding the symptoms of which he gives an excellent account, we note that he says "the onset happens mostly at night," this is certainly not our experience, and in the cases which we have met where the onset was nocturnal, alcoholism played an important part.

Under morbid anatomy, he draws an argument from the characters of the blood. "The blood," he says, "as in all cases of septic disease, is invariably fluid, extremely dark in color, and decidedly acid," but what of that, considering we do not know the exact causes which bring about this condition in "septic disease."

We can find nothing worthy of the adjective "peculiar" in the very slender and incomplete details given of the geographical distribution. Dr. SAMMON says that sunstroke is unknown in Europe, yet we find three undoubted cases in Hilton Fagge which occurred in Bristol.

"*Sirosis* is characteristically a land affection," but we read it is common on board ships in the Red Sea, and not unknown in the Persian Gulf; this is only what we would expect, for sailors know no hotter quarters.

As for epidemics, as the term merely means that numbers of people are affected at the same time, there is nothing peculiar in the fact that this should be so, as the conditions sufficient to produce sunstroke in one are very likely to produce it in a number.

Physiological conditions, which no doubt play a most important part, are dismissed in a very light and airy way, altogether out of proportion to the influence usually assigned to them.

Dr. SAMMON tells us that "the specific organism of *sirosis* is probably spread in the superficial layers of the soil, like other pathogenic micro-organisms, and may be conveyed to man with dust blown by the wind, or thrown up under the tread of marching columns."

It is a matter for regret that he did not find this micro-organism before predicting its existence in such an unconvincing manner.

We do not know if Dr. SAMMON holds that *sirosis* spreads from man to man, at any rate he gives us no instance of this mode of infection.

Taking his paper as a whole, we consider that he has not advanced a particle of reliable evidence in support of the extraordinary hypothesis he has taken up. He has however conferred a great benefit upon us by opening our eyes to the fact that on the subject of sunstroke there is still much to be done by accurate observation and details of cases. Sunstroke has been too much looked upon as *une chose jugée*, this can no longer be the case.

We are aware that a very large number of cases occurred amongst the troops engaged in the recent Frontier Campaign. Many of our readers must be well acquainted with many of them, and we will gladly welcome to our columns any communications or observations under this head, embodying the date, place and general circumstances under which the attack took place, the time of seizure, and the conditions of the atmosphere as to heat and moisture as far as possible.

—:o.—

THE LIFE AND TIMES OF THOMAS WAKLEY, FOUNDER OF THE LANCET.

THE pages of the *Lancet* offer numberless examples of WAKLEY's "shortest way with dissenters" from orthodox medical faith. He had a genuine horror of quacks, and was keenly alive to the wrongs which the medical profession suffered then, as it suffers now, from the lying statements and impudent pretensions of charlatans.

As good examples of his methods, the exposures of CHABERT, the "Fire King," the O'KEYS, and Dr. ELLIOTSON's mesmeric mediums may be mentioned.

CHABERT was a blatant quack, a fire-eater, a prussic acid swallower, and an obviously vulgar impostor. Dr. ELLIOTSON was one of the most distinguished physicians of his time.

CHABERT flourished in London at the end of 1829. He claimed to be able to drink boiling water. Oil at a temperature of 350°F and molten lead and various poisons including prussic acid, arsenic and phosphorus. WAKLEY designated him the "Fudge King" and announced his intention of exposing him.

Accordingly, on the 4th February 1830, the Argyl Rooms, where CHABERT was accustomed to perform these feats, was crowded by a large number of scientific men. CHABERT opened the ceremony by denying that he had ever made the above statements, but was granted by shouts of ridicule in the midst of which WAKLEY advanced to the stage, he produced a small vial of prussic acid

from his guests, when he presented to them the "Pain King," warning them at the same time that he would be dead in an hour if he drank it. The poor Christian tried in vain to break WAKLEY'S invitation and to get a hearing. It was useless, and he fled from the stage amidst the wildest excitement, and was obliged to take refuge in a side office to avoid the fury of the audience.

Dr. ELLIOTSON was a very different person. He was the senior physician on the staff of University College Hospital and a man who held a deservedly high position in the profession; such being the case, the story of his connection with animal magnetism, and of his experiments in a kind of black art, conducted at University College Hospital, forms one of the most extraordinary pages in the medical history of the century.

ELLIOTSON was a man of a very original turn of mind and a great experimenter, and in all that follows, he was held by those who knew him to have been more of a dupe than a ruse. First he took up a certain Baron DUPREY, who claimed to cure epilepsy by a mesmeric sleep; then he took to employing mediums in the persons of ELIZABETH and JANE O'KEY.

These two hysterical girls being thrown into slumber were invited to tell the time by watches applied to their elbows or navels; were asked questions as to the proper medical treatment of themselves and other patients, etc.

These proceedings led to considerable uneasiness and discussion amongst the Governors and staff of the hospital to which WAKLEY'S attention was attracted, and in the *Lancet* he pointed out with his unerring, cool common sense that the whole solution of the question lay in the question whether the O'KEYS were honest and trustworthy or not.

To test this point an exhibition was held in WAKLEY'S house in Bedford Square, when the girls totally failed to act up to their assumed character, and were completely exposed as imposters.

The result was that ELLIOTSON was pronounced to be unfitted for the responsible post of senior physician to University College Hospital, and was forced to resign.

The refusal of insurance companies to fee the profession for the medical examination of their clients was another grievance which WAKLEY successfully combated. In 1840 he took up this subject in the *Lancet*; he held that the policy of the companies in withholding from medical men the remuneration to which their services clearly entitled them was suicidal and also mean. Why, he said, should such advice be rendered gratuitously? Let the medical man make it clear that he would not answer the questions of a life insurance office unless he was properly paid for his trouble, and the companies would sooner or later make advances towards them.

In competition with the older companies a new one was started called the New Equitable, of which WAKLEY was a director; the first prospectus stated that "all medical questions shall emanate from and the answers be directed to their own medical examiners;" also a payment of two guineas was to be made to every legally qualified medical practitioner for every official report rendered by him to the medical examinee of the company.

This company met with great success and speedily outdistanced many of its rivals and brought about the change in their attitude to the medical adviser, which to the benefit of the profession exists at the present day.

In 1851 WAKLEY began in the columns of the *Lancet* the most useful agitation in favor of legislative reform that ever engaged his attention. It was in this year that he decided to issue the results of microscopical and chemical analysis of the food-stuffs, solid and fluid, in general consumption by the nation.

The scope of the inquiry was to form an attack upon prevalent methods of adulteration and sophistication of food, so thorough and uncompromising that it would on the one hand frighten individual evil-doers into better behavior and on the other open the eyes of Parliament to the absolute necessity for State interference.

A number of articles, including coffee, sugar, arrowroot, oil, mustard and bread were submitted to the most exhaustive analysis and the results published; these were startling and showed that the most gross and extensive frauds were being perpetrated. A very large amount of interest was at once aroused; the popular excitement created by these revelations transcended even WAKLEY'S enthusiastic expectations and made legislation against such abuses a matter of immediate importance. A select Parliamentary Committee was appointed in 1856, and the result was the first General Adulteration Act, which became law in 1860.

To any one who has read this brief account of WAKLEY'S life, it must be evident that the amount of work he got through day by day must have been enormous. The following is a programme of his regular day's work for twelve years. At eight in the morning WAKLEY would arrive at the *Lancet* office, breakfast and go through his letters. Soon after the parish clerks and coroners' officers would arrive and the list of inquests for the day would be made out. Then the editorial work for the day would be arranged, concerning which WAKLEY was most precise in his directions, allotting it with every precaution to secure the most useful information and the most trustworthy results for his readers. By nine his carriage with fast trotters would come to the door and he would start on his round of inquests. He rarely returned before six, and usually took his luncheon in his carriage, where he had elaborate arrangements both for feeding and writing. On completing his round, if necessary, he would attend any committee of the House to which he belonged, arriving back at the office by six o'clock. He would then sleep for an hour or so. On waking he would put in order what he had written while driving from one court to another, would look through the "copy" which had been sent in by the staff during the day and finally interview the printer. Then he would go to the Reform Club or to Bedford Square for dinner, thence to the House of Commons. On returning from the house possibly at a late hour he would finish dealing with the voluminous correspondence of the day, answering such communications as must necessarily be replied to under his own hand, regardless of the flight of time, and making notes in other matters to be dictated in the morning.

All this work was done with an enthusiasm which reduplicated the wear and tear as though he were determined to exhaust his heart and nerves as much as his muscles.

In 1850 he felt the first warnings that he was overtaxing his strength, and he made a few attempts at

relaxation, one was outlined in a memorable letter to his friend, DOUGLAS JERROLD.

WAKLEY's idea of a holiday, however, was simply to change the sphere and scene of his labors, not to abate them. In 1851 came the serious breakdown. One night he was found by a policeman unconscious outside the door of the *Lancet* office. He had that day started at sunrise from Harefield, had held seven inquests in different parts of his great district, and had been unable to snatch more than a hurried mouthful of food; he then had to go to the House on important business, and it was midnight before he left Westminster. He then started for the *Lancet* office to attend to his correspondence. The test was too much even for him, and he fainted at the door.

This occurrence put him seriously on his guard, and in 1852 he resigned his Parliamentary duties.

In 1857 Mrs. WAKLEY died, and he then handed over a share in the management of the *Lancet* to his sons.

In the winter of 1860, he began to be troubled with a persistent and severe cough, attended by occasional attacks of hæmoptysis, and it was soon seen that he was seriously ill and losing flesh steadily though slowly. Still he kept working on with the same enthusiasm as of old, until in January 1861 marked debility awoke him too late to a sense of the urgency of his symptoms; he accordingly placed himself under medical treatment at Brighton and for a time made steady progress towards recovery.

It was not to be however: constant attacks of hæmoptysis wore him out, and in October 1861 he sailed for Madeira. He here hired a small house with large balconies, standing in a grove of trees, and settled down for the winter to live a life as far as possible out of doors in the balmy atmosphere.

He made many friends, and the English colony were surprised to find one with so redoubtable a reputation, simple, unostentatious, a pleasant companion, full of reminiscences but not in the least egotistical, an expert chess and whist player, and one in particular whose interest in life had not decreased with his frailer hold upon it.

His appetite returned, his weight increased, and in a letter dated 19th April 1862 he said that his restoration to health was sufficient to warrant him in hoping that he would be able in a very few weeks to return home and resume his official duties as coroner. But it was not to be! The end was not far off. On 11th May when landing from a small boat, he slipped and fell on the beach and the fall brought on severe hæmorrhage from the lungs, from which he never rallied.

He died peacefully and painlessly five days later. His body was embalmed in accordance with his expressed wishes, brought to England, and buried in Kensal Green Cemetery, where his wife and daughter already lay.

The following words of the late Sir JOHN ERIC SMITHSON will be found in a letter addressed by him to the Editors of the *Lancet* and published in that Journal, 26th December 1895:—

"The present generation of medical men know little of him (WAKLEY) and are for the most part ignorant how much they owe to him for exposing and fearlessly attacking the manifold abuses that existed in every department of the

profession, in the colleges, hospitals and medical schools in the first third of this century. Corruption, jobbery, nepotism, promotion by purchase, were rife in the colleges and hospitals, and medical education was at a low ebb when WAKLEY entered upon his career as a journalist. By his outspoken and fearless denunciations of these abuses he brought about their reform and so cleared the road to fame and fortune for those members of the profession who had to rely solely on their own ability and power of work. It was in fact Mr. WAKLEY who made a WILLIAM JENNER or an ANDREW CLARKE possible."

Surely this high estimate of the value of WAKLEY's work was just.

—10:—

THE FIFTEENTH MEETING OF THE COUNCIL OF THE INDIAN MEDICAL ASSOCIATION.

IN accordance with Notices issued by command of the President, the Fifteenth Meeting of the Council of the Indian Medical Association was held at its Office, 50 Park Street, Calcutta, on Friday, the 13th May 1898, at 6 P.M.

Present.—Dr. LAL MADHAB MUKERJI, Rai Bahadur (President, in the Chair), Dr. E. W. CHAMBERS (Vice President), Drs. J. G. ANDERSON, K. G. SIKKAR, R. D. GHOSH and J. R. WALLACE.

Business.—(1). The Notice calling the meeting having been read, the Minutes of the last regular meeting of the Council was read and confirmed.

2. The Secretary represented that in obedience to the resolution of the Council passed at its last meeting, regarding the memorial of the Independent Medical Practitioners of Mussoorie, the following letter had been addressed to the Government of India:—

TO THE SECRETARY TO THE GOVERNMENT OF INDIA,
HOME DEPARTMENT, SIMLA.

Calcutta, 21st May 1898.

SIR,—I have the honor, at the direction of the Council of the Indian Medical Association, to forward the annexed correspondence, consisting of (1) A Memorial from the British Medical Practitioners of Mussoorie to the N.-W. P. and Oudh Government, seeking redress of their grievance on the ground of the Civil Surgeon competing with them in private practice, such competition, owing to the Civil Surgeon's official position, seriously handicapping the memorialists in their legitimate sphere of work. (2) The reply of the N.-W. P. and Oudh Government to the said Memorial, and (3) The representation of the Council of the Indian Medical Association to the N.-W. P. and Oudh Government in connection with the above.

The Council feel that the Memorial of the British Practitioners of Mussoorie, points to a very distinct hardship and grievance, as well as to a violation of the avowed policy of Government which prohibits officials from engaging in private remunerative work. The Council further desire to emphasize the fact that the reply given by the N.-W. P. and Oudh Government to the Memorialists accentuates the need and the justice of the prohibition of private practice to a hard-worked and over-burdened medical officer, if not in the interests of the Memorialists, certainly in the interests of the public. It is the bounden duty of the Council to respectfully claim the best atten-

tion of the Government of India to the important principle that underlies the question of prohibiting highly-paid State Medical Officers responsible for important duties, from infringing a definite ruling of Government which is stringently applied to all officers of the State Service, but which rule hitherto has not been made applicable to officers of the Indian Medical Service. It is important and necessary in this connection, to urge that the conditions of supplying the public needs of the inhabitants of large Indian cities, more especially provincial capitals and hill stations, have materially altered during the past ten years, and that in all these centres there is a sufficiency of British Medical Practitioners, as well as highly trained and fully qualified Indian Graduates of Medicine, to supply the needs of the public, both European and Indian, and that therefore the time for withdrawing the privilege of private practice to State-paid doctors has unquestionably arrived.

The Council, having regard to the argument or reason for the continuance of the privilege of private practice to State-paid Surgeons, viz., that by such monetary inducements the best class of medical men are attracted to the Service, while neither admitting the justice nor the need for any such inducement to candidates to enter the Service, desire to suggest, that while prohibition of general and family practice should be maintained against State-paid doctors in large cities and hill stations, the Council do not at present urge the withdrawal of the privilege of purely consultative practice to State-paid doctors, i.e., their consultation with family physicians and general practitioners.

In conclusion, the Council entertain the earnest hope that the continuance of the present unsatisfactory conditions of medical practice in the large cities and hill stations of India, which entail so much hardship on the independent medical profession of the country, both British and Indian, will be recognised by the Government of India as necessitating the prompt and effective interference of the Government, especially as on the grounds of established principle and acknowledged State policy, the Council of the Indian Medical Association cannot refrain from protesting against this anomaly, nor can they remain satisfied till the Government of India has given effect to their claims and appeals for State protection of the rights and privileges of the local medical profession, both European and Indian.

I have the honor to be,
Sir,

Your Most Obedient Servant,
JAMES R. WALLACE, M.D., F.R.C.S.,
Secretary, Indian Medical Association.

3. The Secretary represented that in obedience to a resolution passed at the last meeting of the Council regarding the complaint received from the Civil Assistant Surgeons of the N.-W. P. and Oudh, to the effect that they were by certain recent orders of their Government, being deprived of their position as *Gazetted Officers*, he had written to the Government on the subject and had received a reply stating in effect that the complaint was not correct. The following is the Secretary's letter and the reply of the N.-W. P. and Oudh Government:—

OFFICE OF THE INDIAN MEDICAL ASSOCIATION,
150, Dharamtala Street, Calcutta, 24th April 1898.
TO THE SECRETARY TO THE GOVERNMENT,
North-West Provinces and Oudh.
SIR,—Would you be so good as to allow me to have a copy of the recent orders of your Government in regard to the Civil Assistant Surgeons of your Provinces which deprive them of the position of gazetted officers.
I have &c.,
(Sd.) JAMES R. WALLACE, M.D., F.R.C.S.,
Secretary, Indian Medical Association.
1480
No. 11—of 1898
11-490 A.

FROM THE UNDER-SECRETARY TO GOVERNMENT,
N.-W. Provinces and Oudh.
TO THE SECRETARY, INDIAN MEDICAL ASSOCIATION.
Dated *Meerut*, 24th May 1898.

SIR,—In reply to your letter dated 24th April 1898, I am directed to say that no such order as referred to by you in regard to Civil Assistant Surgeons of these Provinces has been issued by this Government.

I have the honor to be,
Sir,
Your Most Obedient Servant.
(Sd.) H. W. WRIGHT,

Under-Secretary to Government, N.-W. P. and Oudh.

4. The Secretary represented that he had received the following letter from the Military Department of the Government of India, in reply to the letter of the Council in regard to the grievances of Military Assistant Surgeons and Military Hospital Assistants:—

NO. 2061 D.
MED. DEPT. GOVERNMENT OF INDIA,
Subordinate. Military Department.

Simla, the 5th May 1898.

TO THE SECRETARY, INDIAN MEDICAL ASSOCIATION,
150, Dharamtala Street, Calcutta.

SIR,—I am directed to acknowledge the receipt of your letter dated the 23rd March 1898, making certain suggestions for the amelioration of the grievances of Military Assistant Surgeons and Military Hospital Assistants in regard to status, pay and allowances.

2. In reply I am to say that the question of improving the prospects of the Military Medical Subordinates in question is now engaging the attention of the Government of India.

I am, Sir,
Your Most Obedient Servant,
(Sd.) J. PHILLIPS,
Offg. Asst. Secy. to the Govt. of India.

5. The Secretary represented that in view of the frequent discussions by the Council on the subject of medical education, medical examinations and medical diplomas in India, and in view of the hardship that ensued both to the general public and to the various grades of medical practitioners in this country owing to the unsatisfactory and irregular condition of these matters, the time had arrived when definite action should be taken by the Council, and he proposed that the following letter be approved of by the Council and forwarded without delay to the Supreme and Provincial Governments and to the various administrative medical and educational authorities concerned. The Council unanimously approved

of the letter and it has been despatched to the Government. It is as follows:—

TO THE CHIEF SECRETARY TO THE GOVERNMENT OF INDIA,
Calcutta, 20th May 1898.

SIR,—The subject of reform in medical education and examinations has come prominently to the front in India recently. The *Indian Medical Record*, the organ of the local profession and of this Association, has voiced the public sentiments and views on this subject for the past ten years, and the Council realised most keenly that the time has come when action should be taken to place the question of reform in medical education and medical examinations before the Government, in view to a definite and equalised standard being adopted for the Colleges and Schools of the country.

The Council feel that were they to outline the direction in which reforms should be made, they would indicate them as follows: (1) a uniform standard of preliminary examination; (2) a uniform standard of education and professional examination; (3) the formation of a Council to exercise disciplinary powers similar to those of the General Medical Council of Great Britain.

It may be interesting, while placing the subject of these necessary reforms before the Government, to take a glance at the condition of medical education and examinations in the Indian Empire.

In the first place we have no body comparable to the General Medical Council to supervise education and protect the public from the dealings of unqualified persons. In India everything is in the hands of the Government of the country, and it may be well in this connection to ask—How does the Government look after the interests of the public by upholding the standard of medical education?

As a question of practical importance, it seems to have been altogether lost sight of, so varied and widely divergent are the standards with which we are surrounded, while the number of new schools constantly arising and granting their own diplomas, must strike dismay into the minds of those who are interested in the future welfare of the medical profession in India.

The uniform standard of professional examination, the one portal system for each class, so ardently hoped for by many Indian reformers, is considered as entirely within the bounds of possibility in a country like India, where the State is all powerful and the vested interests are few, so that the question presents no obstacles that cannot be easily overcome.

At the present day, competition with Government schools by private institutions hardly exists in India, but that it will arise in the future, if not prevented, no one can doubt. The existence of two such diploma granting schools in Calcutta is proof of this assertion.

Unfortunately in this country, at the present day, the tendency is to lower and not to elevate the standard of medical education; for we find the Government willing to accept anything in the shape of a "diploma" as good enough for its own local services and for the medical requirements of the public.

This is a question which demands the earnest attention not only of the Government but of the universities. It is obviously one of the chief functions of a university to uphold and elevate the standard of education, and if it

fails to do this, its influence and importance must become depreciated.

Now what is to be said of a university that, without protesting, permits private bodies to grant counterfeits of its degrees? What can we say, except that it has become a nonentity as far as its influence over education and even over its own rights is concerned.

Yet we have several bodies granting hybrid diplomas. There is the V. L. M. S., which stands for Vernacular Licentiate of Medicine and Surgery, L. T. M. S., Licentiate of the Temple Medical School. What are these but imitations of the L. M. S. degree of the universities?

These titles are astonishing enough, but what strikes us with utter amazement, is to find the exact counterpart of the university degree granted under the auspices of the Dufferin Fund. How has it come to pass that this Fund grants a License in Medicine and Surgery?

The whole question must be raised as to the legality of these licenses. Under what authority are they given and what benefits do they confer? Are the holders of them held to be qualified practitioners in the eyes of the law?

The criterion of qualification in Great Britain is Registration under the Medical Acts of the United Kingdom. The degree or diploma in itself is not sufficient to constitute a qualified practitioner, it only enables the holder to be registered. It is registration which confers the benefits according to qualification.

A person who is unregistered is unqualified before the law.

What is the criterion of qualification in India? Under what authority do these different schools, and even private bodies, grant licenses to practise Medicine and Surgery, and who is responsible that the education given by all these bodies is up to the necessary standard? All these are matters which require elucidation, and it is to the interest of all concerned that they should be put on a proper footing by the Government of the country.

When we turn to the universities themselves, we find some anomalies for which we can discover no reason. It is a curious thing that the standard of preliminary education demanded by all is not the same.

In Bombay and Madras the Matriculation opens the way for the L. M. and S. In Calcutta it is necessary, in addition to the Matriculation, to pass the First Arts, and in the Punjab University the Intermediate is required. From this we conclude that the standard of preliminary education is lower in Madras and Bombay than it is in Calcutta and Lahore, and it is obvious that if it were not for the greatness of the distances in this country, most of the students requiring medical qualifications would flock to the two former universities.

Again, there is no uniformity in the degrees that Indian Universities grant. Surely in these minor matters much might be gained by adopting the same nomenclature. At present the Calcutta University grants a License in Medicine and Surgery. Bachelor in Medicine and Doctor in Medicine. Madras University grants a License in Medicine and Surgery. Bachelor of Medicine and Master in Surgery, and Doctor of Medicine.

Bombay University grants the degree of Licentiate of Medicine and Surgery, and Doctor of Medicine, but no Bachelor's degree.

To what extent are all these differences and minute distinctions?

Uniformity of examination and qualification is required also in the Military Assistant Surgeon class. At present these colleges grant diplomas to these men, and the diploma is different in each case. The Calcutta Medical College grants the D. M. C. C. Diplomas Medical College, Calcutta. The Grant Medical College, Bombay, grants B. G. M. C., and the Madras Medical College D. M. M. C. All these colleges might easily give the same title, say Diplomas in Medicine, Surgery and Midwifery. (D. M. S. M.) The educational standard for Military Assistant Surgeons should be fixed at the University Entrance; the course of study should be extended to five years, and there should still be a preliminary competitive examination.

Much reform is required in the education of Hospital Assistants and the junior class of practitioners on a level with them, who are turned out of State and private medical schools. At present they are all educated in the vernacular. They should all be educated in English; in fact there should be an English test before they enter upon their medical studies. Finally, there should be one standard examination for all the Government schools that turn out this class of men, their course of study should be four years, and they should receive a definite qualification, say a Certificate in Medicine, Surgery and Midwifery (C. M. S. M.) Private medical schools, which train this particular class, should be placed under State inspection as regards their standard of education and examination and their alumni should be compelled to pass the State examinations of their class. Certificates of qualification should be granted alone by the Government.

It is, however, when we come to consider the mode of appointing the various professors in the different universities that we hit upon the most curious anomalies of all. In making these appointments the Government apparently thinks that because a man holds a good "qualification" he is fit to "profess" in any subject. Doubtless many of those selected would, if given a fair chance; but few possess the necessary versatility to profess in Chemistry one month, in Pathology the next, and perhaps in Obstetrics the next. Yet the exigencies of the service are so great and the tenure of office so uncertain, that this is what is actually demanded. Far more attention should be given to the selection of men for these posts, and the period of office should be fixed, and the longer the period the better, provided the right man was secured for each chair.

In conclusion, the Council of the Indian Medical Association desire to urge the following points in connection with medical education and medical examination upon the serious and early consideration of the Government:—

(1). A unified standard of preliminary examination in general education for admission to medical study for all universities in India. As the F.A. of Calcutta and the Intermediate of Lahore are already accepted by two universities, the other academical bodies should be asked to raise their preliminary educational standard to this level.

(2). That the medical degrees granted by Indian Universities be of one standard, and one nomenclature namely:—

- (a) Licentiate of Medicine and Surgery or L.M.S.
- (b) Bachelor of Medicine or M.B.
- (c) Master of Surgery or C.M.
- (d) Doctor of Medicine or M.B.

No imitations of these degrees should be permitted.

(3). A unified standard of preliminary examination (the Entrance or Matriculation of Indian Universities or the High School Certificate) a full curriculum (5 years) and a unified diploma (Diplomate in Medicine, Surgery and Midwifery or D.M.S.M.) for all Military Assistant Surgeons.

(4). A unified standard of preliminary examination (the Middle School Examination of the Government European Code or its equivalent Entrance), a curriculum of four years' medical study, and a unified professional examination and certificate of qualification for all Hos-

pital Assistants, whether civil or military, and for all junior medical schools, whether State or private. Certificate in Medicine, Surgery and Midwifery (C.M.S.M.)

(5). The formation of a General Medical Council for India (with powers similar to the General Medical Council of Great Britain) composed of an equal proportion of Government officials and independent medical practitioners.

The Council desire to press for the urgent attention of these matters by the Government, as not only do they point to a most chaotic and unsatisfactory condition of affairs medical, but the continuance of their existence is calling into being, uncontrolled, private institutions, which are claiming not only to educate in Medicine, but are granting diplomas to practice the art of Medicine, Surgery and Midwifery. The Council claim that as the representative of the medical profession in India, it would be failing in its duty to the Government, the profession and the public if it did not strongly urge the importance and real necessity for State interference in the matters herein referred to.

I have the honor to be,

Sr,

Your Most Obedient Servant,

(Sd) JAMES R. WALLACE, M.D., F.R.C.S.,

Secretary, Indian Medical Association.

6. The Secretary represented that in view of the strong public feeling that was being evoked in Calcutta and elsewhere, concerning the recent Plague Regulations promulgated by the Bengal Government, and in view of the doubts expressed concerning the real existence of true plague in Calcutta, it seemed imperative that a society of medical men representing the entire local profession of India should utilise such an opportune occasion for the expression of its views on the subject for offering some suggestions calculated to assist the Government in directing its policy to the best public advantage. The Secretary placed a draft letter before the Council and the same was unanimously approved. It has been duly despatched to Government, and is as follows:—

TO THE CHIEF SECRETARY

TO THE GOVERNMENT OF BENGAL, Calcutta.

SIR,—I have the honor to request that you will kindly place the following Resolutions, passed at a meeting of the Council of the Indian Medical Association, held at its Office in Calcutta on the 18th May 1908, before H. H. the Lieutenant Governor of Bengal for his consideration:—

I. That the Council of the Indian Medical Association, fully appreciating the difficulties of the Bengal Government in dealing with the social and religious aspects of its plague regulations as they affect the Indian community, desires to express its earnest sympathy with Sir JOHN WOODBURN and his Government in the present circumstances. It further desires to express its grateful appreciation to Sir JOHN WOODBURN for the sympathetic and considerate attitude he has assumed in respect to the feelings and caste and religious usages of the native population while framing the regulations of the Government for the prevention of plague.

II. That in view of the present state of unrest and distress of the Native mind in Calcutta, and in view of the unfortunate consequences arising therefrom, and further having regard to the fact that there is considerable doubt among medical men as to the real existence of true plague in our city, the Council desires to urge the following suggestions for the early attention of the Bengal Government:—

(1.) That a definite declaration be made of the diagnosis of the case now being pronounced as plague, based upon the following conditions:—

(a.) The decision of a committee of qualified official and non-official physicians, given after consultation together

on any case or cases of suspected plague, after a careful examination of such case or cases and after due discussion among themselves of the recognised clinical signs and symptoms of the disease.

(b) The decision of two competent bacteriologists residing in Calcutta (we would suggest Surgeon-Colonel G. BOWRON, M.D., First Physician to the Medical College Hospital, and Surgeon-Major J. F. EVANS, M.D., Professor of Pathology of the Calcutta Medical College), who shall declare their opinions on the microscopic and bacteriological appearances of the blood of such patient or patients.

(c) To confirm the bacteriological opinions of these two reputable pathologists, by reproducing plague experimentally in dogs or rabbits inoculated with the blood of such patients.

(d) To depute MONSIEUR HAFKINE and one of the following officers (Surgeon-Colonel EDWARD LAWRIE, Surgeon-Major DONALD BORN, Surgeon-Major PATRICK HEBER, or some other official specialist in microscopy and bacteriology), to express an independent opinion on the same lines of research.

III. That in view of the probable presence of plague and the possibility of an epidemic extension of the disease in the city, the following measures be immediately adopted:—

(a.) A thorough cleaning up of the whole city.

(b.) The opening up of crowded areas, the remodelling or destruction of unhealthy houses, and the formation of a few large, straight, wide streets running from East to West, and from North to South of the town.

(c.) That the Health Officer be not permitted to employ his time in any other way except in fulfilling those duties which are strictly involved in the true sanitary interests of the town.

IV. That the Government will endeavour to restore confidence, peace and happiness to the inhabitants of the city, chiefly the native population, by adopting such measures for the prevention of disease which, while they ensure public safety, do not conflict with the social customs, caste prejudices and other religious feelings of the Hindu and Mahomedan communities.

V. In connection with the above Resolution, the Council desire to invite the attention of the Government of Bengal to the representation made by the Council to the Government on the 23rd March 1897 on the subjects of the Sanitation of Calcutta and Plague Regulations.

I have the honor to be,

Sir,

Your Most Obedient Servant,

(Sd.) JAMES R. WALLACE, M.D., F.R.C.S.,

Secretary, Indian Medical Association.

7. The Secretary placed before the Council a representation from Mr. DEO LAL, a Civil Hospital Assistant, of the Central Provinces, complaining of his wrongful dismissal. Mr. DEO LAL's case was duly considered together with the representation made by his solicitors, Messrs S. J. LESLIE and SONS of Calcutta, and the Council being satisfied that Mr. DEO LAL's case was deserving of its support, have forwarded the same to the Director-General, Indian Medical Service, for favorable consideration.

8. The Secretary reported that 12 new members had applied to be admitted to the Association since the last meeting of the Council. They were all duly elected. He further reported that 21 new members had joined the Indian Medical Association Provident Fund, thus bringing the total membership of the Fund up to 220. The Council again regretted the apathy of members of the Association in joining the Provident Fund, and once more appealed to all those concerned in its success to become members of the Fund without further delay.

8. With a vote of thanks to the chair, the meeting was closed.

COMMENTS AND NEWS.

PETTICOAT GOVERNMENT IN PLAGUE MATTERS.

It is a curious instance of the petticoat government which rules supreme in India that a great city like Calcutta cannot take the initiative in providing itself with a competent bacteriologist at the present crisis. Even the Bengal Government seems to be powerless in the matter, and the Government of India has to be besought to procure one. In this, as in all other questions relating to medicine, it has shown itself to be somewhat tardy.

The following letter in reply to the Secretary of the Bengal Chamber of Commerce, dated 16th May 1898, speaks for itself:—

"SIR,—I am directed to acknowledge the receipt of your letter No. 639, dated the 13th of May 1898, in which the Chamber suggest—

(a.) The advisability of engaging, as early as possible, the services of a bacteriologist of the highest attainments to investigate and report on the cases of plague which have recently occurred in Calcutta. The Chamber are of opinion that if such an officer can be obtained, the appointment should be made permanent, so that whenever outbreaks of epidemic disease take place they may be promptly and fully investigated.

(b.) That pending the appointment of an officer such as above described, the cases of plague already reported being few in number, a committee of medical experts, consisting both of official and non-official medical men, be appointed to determine whether the disease can now really be said to exist in the city.

(c.) That, in order to restore confidence in the minds of the people, an official declaration be made that plague does not exist in the city in an epidemic form.

2. I am directed to reply, as follows, to each of the suggestions made by the Chamber:—

(a.) A reference was made to the Government of India some time ago on the general question of making adequate provision for bacteriological research, and they will now be addressed again on the subject. The Chamber will understand that an incompetent bacteriologist would be worse than useless.

(b.) Under the Venice Convention the occurrence of even a single case of plague must be reported officially. A number of such cases have occurred which have been pronounced to be plague by the leading medical men, official and non-official, in Calcutta, and their unanimous opinion has been continued by the independent scientific testimony of Mr. HAFKINE. If the Chamber would like to depute any medical practitioner to see the cases in hospital every facility will be given by the Health Officer for his seeing them.

(c.) Plague does not at present exist in an epidemic form, but it will certainly assume that form if all suspicious cases are not promptly reported and dealt with under the rules.

I have the honour to be, Sir, your most obedient servant,—
H. H. RISLEY, Secretary to the Government of Bengal."

MEDICAL EXAMINATION FOR LIFE INSURANCE.

DR. CALWELL read a paper at the Ulster Medical Society upon Moot Points in the medical examination of life insurance cases. He advised a good general physical examination of applicants, but thought some of the schedules in use quite too minute. The use of the ophthalmoscope, laryngoscope, and clinical thermometer might be reserved for cases with special indications. In cases where cardiac mischief was

and the remaining conditions. As regards the insurance of joint disease—(a) syphilis—an applicant was insurable under the same circumstances as marriage, was permissible, that is, thirty years after the initial cure, with due care's freedom from symptoms. (b) Hemoptysis: Apertifluen obvious disease in other organs, nearly all these cases were tuberculous and the risk must be adjudged accordingly; (c) Alcoholism: Permanent reform was rare, and these cases were rarely insurable; the testical section in various companies showed a decidedly better expectation of longevity than the general section; (d) Pleurisy: It should be borne in mind that a certain considerable proportion of these cases ultimately became tuberculous. As regards heredity, a family history of longevity was very important, but no material help could be derived from such considerations as prepotency, different ages of parents, etc. Of the points arising in the physical examination of applicants the following was important: (a) Pulse, or the whole cases with low tension of pulse had less vital resistance than those with higher tension, but regard must be had to pathological increase of tension. Intermittency must be interpreted in the light of its cause. Epigastric pulsation was not of much significance. As regards valvular disease, cases with aortic reflux or mitral stenosis were not insurable, but mitral regurgitation was not a complete bar. In such cases, provided there were no cardiac symptoms, no evidence of changes in the myocardium or chambers, general nutrition and habits favorable, the risk might be taken with a heavy addition. The importance of hoarseness depended on the result of laryngoscopic examination. As regarded albuminuria, permanent albuminuria was a complete bar, but cases of the so-called "cyclic albuminuria" required much consideration and repeated examination. In the absence of a history of nephritis or evidence of renal change, the insurability of these cases might be entertained. As regarded glycosuria, if temporary, under control by dieting, and if the family history was good, it did not preclude insurance.

CURIOSITIES OF MEDICINE.

"ANOMALIES and Curiosities of Medicine" by Drs. GEORGE M. GOULD and WALTER L. FYLE is a book which must command the attention and interest of all medical readers. It is a complete epitome of nature's eccentricities collected from all the most reliable sources. It is more than a mere compilation; for the authors have not only ordered and arranged their facts in an admirable manner, but they have digested and set them forth in the form of a most readable book—a book which stands apart from all others, and makes an era for itself.

The attraction which the fabulous, the marvelous or the merely extraordinary possesses for minds of every description is well known, and the ever verdant interest of fairy tales bears out the fact, this work however, appeals to the higher understanding and even in the realms of the fabulous, touches and moves the scientific sense.

Imaginative medicine is well illustrated in the following extract:—

"L. G. CAPERS of Vicksburg, Miss., relates an incident, during the late Civil War, as follows: A matron and her two daughters, aged fifteen and seventeen years, filled with the enthusiasm of patriotism, stood ready to minister to the wounds of their countrymen in their fine residence near the apex of the battle of H—, May 13, 1863, between a portion of Grant's army and some Confederates. During the fray, a gallant and noble young friend of the narrator's stag-

gered and fell to the earth; at the same time a piercing cry was heard in the house near by. Examination of the wounded soldier showed that a bullet had passed through the scrotum and carried away the left testicle. The same bullet had apparently penetrated the left side of the abdomen of the elder young lady, midway between the umbilicus and the anterior superior spinous process of the ilium, and had become lost in the abdomen. This daughter suffered an attack of peritonitis, but recovered in two months under the treatment administered. Marvellous to relate, just two hundred and seventy-eight days after the reception of the mini-ball, she was delivered of a fine boy, weighing 8 pounds, to the surprise of herself and the mortification of her parents and friends. The husband was intact, and the young mother strenuously insisted on her virginity and innocence. About three weeks after this remarkable birth Dr. CAPERS was called to see the infant, and the grandmother persisted that there was something wrong with the child's genitals. Examination showed a rough, swollen, and sensitive scrotum, containing some hard substance. He operated, and extracted a smashed and battered mini-ball. The doctor, after some meditation, theorized in this manner: He concluded that this was the same ball that had carried away the testicle of his young friend, that had penetrated the ovary of the young lady, and, with some spermatozoa upon it, had impregnated her. With this conviction, he approached the young man and told him the circumstances; the soldier appeared skeptical at first, but consented to visit the young mother; a friendship ensued which soon ripened into a happy marriage, and the pair had three children, none resembling, in the same degree as the first, the heroic pater-familias."

And the following is a good example of rough surgery:—

"MARSH (in the *New York Medical Record*, 1867) cites the case of a woman of forty-two, the mother of eight children, who, when eight months pregnant, was horned by a cow. Her clothes were not torn, but she felt that the child had slipped out, and she caught it in her dress. She was seen by some neighbours twelve yards from the place of accident, and was assisted to her house. The bowels protruded, and the child was separated from the funis. A physician saw the woman three quarters of an hour afterwards, and found her pulseless and thoroughly exhausted. There was considerable, but not excessive, loss of blood, and several feet of intestines protruded through the wound. The womb was partially inverted through the wound, and the placenta was still attached to the inverted portion. The wound in the uterus was Y-shaped. The mother died in one and a half hours from the reception of her injuries, but the child was uninjured."

The first chapter treats of genetic anomalies, the next three of prenatal anomalies, obstetric anomalies, and profligacy. The chapter which follows and deals with physiological and functional anomalies, is especially interesting, as we would expect, in it we have a number of cases of bloody sweat fully discussed, etc.

Other chapters treat of surgical anomalies of the various parts of the body, curious skin diseases. Nervous and mental affections, etc.

From cover to cover the book is full of interest, and the reader is constantly thinking of the immense amount of care and labor that must have been bestowed upon it.

The authors are to be congratulated on having so successfully tackled so Herculean a task.

ADENOID VEGETATIONS IN THE VAULT OF THE PHARYNX.

HISTORICOPY of the pharyngeal tonsil, or adenoma, occurs in two varieties. The first consists of spongy, stellate projections from the vault of the pharynx; the second of smooth fibrous tumors of irregular shape. They are very vascular and contain lymph cells and a follicular structure resembling that of the oral tonsils.

This is mostly a disease of childhood and is oftenest seen under the tenth year.

The most striking features in a pronounced case are the parted lips, prominent eye balls, obliteration of the normal lines of expression of the face and a constant appearance of listlessness and inferiority. Mouth breathing, a noisy respiration, snoring and a lack of resonance of the voice are typical symptoms. There is a characteristic thickness of speech or nasal intonation. There is a copious tenacious discharge of a grayish or bloody color. Examination with the finger causes bleeding. There is a history of recurring colds in the head, catarrhs, diminished hearing, noises in the ears or otorrhoea.

I rely mostly on digital examination in making a diagnosis.

The prognosis is good if the adenoids are thoroughly removed. The natural tendency is to absorption in early adolescence. It is the practice of some rhinologists to treat adenoids with washes, sprays, caustics, the galvano-cautery, etc., for periods varying from four to fourteen months, but I prefer the one, painless operation, lasting but five minutes and insuring a radical cure. The best anesthetic for this operation is ethyl bromide. Before administering it, the little patient should be calmed into a tranquil state of mind, for if there is great excitement, the drug is not so efficacious. The instruments are sterilized by boiling or steaming, and the mouth gag is inserted between the molar teeth. It must be carefully held in place by an assistant until the operation is completed; otherwise it slips out of place and allows the jaws to close, after which they are separated with difficulty. The patient is held in a sitting posture on an assistant's lap. An ounce tube of ethyl bromide is emptied into an air-tight inhaler and administered as in etherization, allowing no air to enter. Anesthesia is induced in about one minute and lasts about five minutes. Not more than half an ounce is taken, but the remainder will not keep for subsequent use. The patient quickly recovers consciousness, and after lying down for a few minutes he is ready to be taken home.

The instant anesthesia is complete, Gottstein's large or small ring curette is inserted behind the velum and upward near the vomer to engage the central highest mass first. Then the cutting surface is passed backward and downward in contact with the posterior pharyngeal wall as far as the growths extend, the same movement is executed on either side wherever there are growths, sweeping them all out by three or four passes of the curette. Finally the finger is inserted to discover if any remnants remain. If so, they may be detached with the finger nail or curette.

As soon as all the adenoid tissue is extirpated, the gag is removed, and the patient's body is inclined forward with the face downward. The surgeon loudly commands the patient to "spit it out!" The blood escapes through the nose and mouth, and the patient at once begins efforts at expulsion. The blood is thus prevented from entering the larynx or stomach.

Hæmorrhage lasts but a few minutes, and generally ceases by the time full consciousness is restored. This method

deprives the operation of the hæmorrhage experienced by children whose adenoids are extirpated without anesthesia.

Although instances of severe hæmorrhage from this operation are reported, I have never witnessed any. In my experience, with a considerable series of cases, none but satisfactory results have been obtained.

One needs to take care not to wound the orifices of the Eustachian tubes, or to drag a mass of the adenoid tissue down into the throat and leave it hanging there by the pharyngeal membrane intact. I have observed this condition after what must have been a hasty and incomplete operation. The finger need not be inserted into the pharyngeal vault while the curette is in action, but one should not fail to examine immediately after curetting to ascertain if the adventitious tissue has been completely removed.

I have never seen any bad effects from the use of ethyl bromide. It is as safe as ether and far more preferable for such short operations.

The operation itself is not difficult, and I have never regarded it as dangerous. It is a simple curettement in an easily accessible cavity, provided the mouth is kept properly gagged.

THE INCOMPATIBILITY OF ANTIPYRIN AND SODIUM SALICYLATE (IN POWDER FORM).

SAYS the *New York Medical Journal*:—"In a letter WILLIAM J. ROBINSON, of New York, calls attention to the fact that antipyrin and sodium salicylate cannot be dispensed together in powder form; immediately, or within a short time, liquefaction takes place and when the powders reach the patient he is likely to find no powders at all, but only thoroughly-soaked pieces of paper. Though for practical purposes it is immaterial whether the change is of a chemical or of a purely physical nature, it is his opinion that the liquefaction occurs in virtue of a true chemical reaction. HELBIG, in his 'Modern Materia Medica,' says:—The reaction of sodium salicylate and antipyrin sometimes stated to be the result of a chemical change, has been decided, by careful research, to be merely the result of deliquescence, the salicylate acting as a carrier of moisture to the more soluble antipyrin (spica). To this statement the author is unable to agree. Sodium salicylate is permanent in the air,—i.e., it does not attract moisture; nor is antipyrin *more* soluble. Rather the contrary. Antipyrin is soluble in 1 part of water, while sodium salicylate is soluble in 0.9 part of water. Nor does sodium salicylate contain any water of crystallization which might be liberated during trituration and act as a solvent for the antipyrin (as is the case with many salts).

"The subject of the incompatibility of the two above-mentioned drugs was recalled to my mind by an occurrence which took place a few days ago.

"A physician was called in to a patient suffering with acute articular rheumatism; the fever was very high, and the pains were excruciating. The doctor prescribed powders of phenacetin, antipyrin, and sodium salicylate, and the druggist was asked to make them up in a hurry. It was a damp evening, and when the medicine was brought to the patient, there was not a particle of powder left, only a box of wet papers. The druggist was asked for an explanation, but he said that it was none of his business, that he made up the prescription as the doctor wanted, and if anything was wrong they should apply to the latter for information. They went to the doctor, he was out, and another physician was sent for. He relieved the patient by an hypodermic injection of morphine and prescribed capsules of phenacetin and salol; he was asked to take further charge of the case. Thus, non-familiarity with the important, but sadly neglected, subject of incompatibilities lost the physician a good family."

APPRECIATION OF MEDICAL WORK.

THE following generous appreciation of the work done by the medical profession is taken from the *New York Evening Post*, 28th March :—

"Those who grumble most over the dues demanded by doctors are least aware what noble liberality is shown by the profession in the gift of their highest skill and of priceless time in which they might refresh themselves, entirely 'without money and without price.' And this, outside the walls of hospitals, merely in response to appeals in behalf of those who were not able to come to them as paying patients.

"I have seen a great specialist gently tear a cheque in two and lay it on a convenient table, after he had made a visit which involved a journey and the loss of half his day, because he knew the money would be a comfort to his patient. And I have known the same man to treat case after case with his utmost skill and care, without a thought of payment; and, if his purse now overflows, he could have doubled his fortune had he always had paying patients.

"That there are many grasping, selfish, and even unjust physicians goes without saying; they are of our common humanity, and no profession, business, or trade is without men with these characteristics; but that as a body, they labor more for the relief of the suffering of the world without adequate reward than any other class of educated men, I sincerely believe, cannot be questioned.

"Their opportunity is unique, but their influence and assistance in the history of our households is a great testimony to the sympathy and patience and large-hearted comprehension of man with and for his fellow-man in this urgent, crowded, self-seeking age of ours. Human brotherhood, which has no name or guild, is vitally alive among our doctors. Sleepless nights and anxious days, hours of tense apprehension, the exertion of almost superhuman ingenuity to relieve pain, mark the going to and fro of many a quick-moving 'buggy' in our busy streets; and if one in a thousand is so fortunate as to acquire wealth as the result of his practice, let us rejoice for him."

CALCUTTA PLAGUE.

SPORADIC cases of so-called plague continue to appear in small numbers and keep every one in a state of tension and alarm. The statistics, however, are so far very encouraging. Up to Thursday, 27th May the total number of recorded cases was 69 and the total deaths 55; in this there is nothing very appalling, while, on the other hand, the total daily death-rate of the city is more often than not, below the average of previous years.

No good will be gained by entering into any detailed account of the various cases from a clinical or bacteriological aspect. Suffice it to say that a considerable difference of opinion prevails, which we leave with an easy conscience to the decision of the future historian.

It is generally conceded on all sides that no such thing as epidemic plague exists in Calcutta at the present time, and with this opinion we are satisfied.

The worst feature of the matter is the excited and highly inflammable state of the native population; the wildest and most improbable rumours are eagerly seized upon, spread broadcast, and accepted with a faith that is positively amazing, there is nothing too wildly, too incredibly impossible to be believed.

The result is a series of disturbances almost amounting to riots, which, if not promptly checked, will lead to a reign of terror for Europeans, and especially for those who are in any way connected with plague work.

Dr. LAING's unfortunate experience, when he was assaulted by a mob, who in its boldness penetrated even into a private house, will be a lesson to all medical men, that it is unsafe to prosecute their ordinary duties unarmed. It was fortunate that Dr. LAING had a loaded revolver, and we congratulate him upon the courageous attitude he assumed in not fearing to use it. The result of his three shots was the retreat of the rioters and the death of two of their number. Had Dr. LAING found himself in this precarious position unarmed, there is very little hope that he would have escaped with his life, and we would have had the sad duty of recording the murder of another European, at the insane hands of an Oriental mob. The moral we read is, that it is high time the authorities saw the necessity of properly protecting all its employees in the pursuit of their duties.

THE FEELING IN DUBLIN IN REFERENCE TO THE ARMY MEDICAL DEPARTMENT.

THE interest which is felt here in reference to the Army Medical Service has been increased rather than diminished by the strangely conflicting replies of the Royal Colleges of Physicians and Surgeons respectively to the request of the Director-General. The Council of the Royal College of Surgeons met on 29th March for the special purpose of considering the matter and after an exciting debate decided to accept the suggestion and to nominate two surgeons for temporary service in the Army Medical Department in reliance on the pledge given by the Government that the newer reforms would be carried out. At a largely attended meeting of the President and Fellows of the Royal College of Physicians, held on 1st April, the following carefully considered resolution was unanimously adopted :—

Pending the issue of a warrant in accordance with the statement recently made in the House of Commons by Mr. POWELL WILLIAMS, M.P., Financial Secretary to the War Office, as to prospective arrangements for improvements in the Army Medical Department, which arrangements, if carried out as indicated, would, it is believed, at once secure a competition by a sufficient number of high-class candidates to fill the vacancies that now exist in the service by competitive examination in the ordinary manner, the College is of opinion that, in the interests of its Licensates and of the Army Medical Staff, it is not advisable that any recommendations for the temporary employment of civil surgeons for duty with Her Majesty's troops in the United Kingdom should be made by the President in accordance with the request made to him by the Director-General.

The College of Surgeons considered the somewhat vague statements as to the new warrant which emanated from Lord LANSDOWNE to constitute the beginning of a new era for the army surgeon and acted on that perfectly natural assumption. The other College decided on not moving until the document itself appears. The resolution of the latter—the College of Physicians—was quoted in full in the columns of the *Irish Times* of 2nd April and formed the subject of one of the numerous leading articles on the matter which have recently appeared in that journal. The general feeling in Dublin seems to be very much what is embodied in the leading article in *The Lancet* of 2nd April—namely, that the Army Medical Staff and the profession are to be congratulated on the very successful issue of their controversy with the Government.

A MEDICAL ENIGMA.

COUNT CRYECK, who claims to be a reduced Bohemian noble, and who for more than a year has puzzled and deluded the cleverest doctors in Chicago, possesses the remarkable gift of being able to simulate any disease under the sun, and to raise or lower his temperature and the beats of his pulse at will.

The Count is a man of thirty-five, of some distinction of speech and appearance, and with a plausible manner which

has never been much in his impotence. He has a craving for order and tidiness; and, as he has not the means to gratify it, he suffers serious illnesses and is removed to one hospital or another, where for weeks he is tenderly nursed and fed on cod-liver oil. In this way he has enjoyed the benefits of every hospital in Chicago, and has successfully deceived every one of his many medical attendants.

His favorite method is to simulate a dangerous fever, and he is able to raise his temperature to 106deg. or 104deg. and to set his pulse galloping at the rate of 130 or 180 to the minute. He can also develop all the symptoms of a wide range of illnesses in such a way as to completely deceive the doctors.

Another favorite plan of this *malade imaginaire* was to be found in the streets in an apparently dying condition as the result of an attempt at suicide. The cause of the rash act was undoubtedly clear from his delirious ravings, in which he would call for "ANNIE, the delight of my life." As the victim of unrequited affection he made a strong appeal to the sympathy of his nurses.

Unfortunately, he was not so constant to "ANNIE" as to his scheme of imposition; and at various hospitals he called for so many different fair ones in his delirium—MARIE, LUCILLE, LOUISA, and so on—that suspicion was aroused and the hospital authorities were led to make inquiries and to compare notes. The result was that the pseudo-Count was placed on their "black list," and he has had to seek a new field for the exercise of his novel arts.

BOARDING HOUSE GEOMETRY.

DEFINITIONS AND AXIOMS.

ALL boarding houses are the same boarding house.

Boarders in the same boarding house and on the same flat are equal to one another.

A single room is that which has no parts and no magnitude.

The landlady of a boarding house is a parallelogram—that is, an oblong angular figure, which cannot be described, but which is equal to any thing.

A wrangle is the disinclination of two boarders to each other that meet together but are not on the same flat.

All the other rooms being taken, a single room is said to be a double room.

POSTULATES AND PROPOSITIONS.

A pie may be produced any number of times.

The landlady can be reduced to her lowest terms by a series of propositions.

A bee line may be made from any boarding house to any other boarding house.

The clothes of a boarding house bed, though produced ever so far both ways, will not meet.

Any two meals at a boarding house are together less than two square meals.

If from the opposite ends of a boarding house a line be drawn passing through all the rooms in turn, then the store-pipe which warms the boarders will be within that line.

On the same bill and on the same side of it there should not be two charges for the same thing.

If there be two boarders on the same flat, and the amount of side of the one be equal to the amount of side of the other, each to each, and the wrangle between one boarder and the landlady be equal to the wrangle between the landlady and the other, then shall the weekly bills of the two boarders be equal also, each to each.

For if not, let one bill be the greater.

Then the other bill is less than it might have been—which is absurd.

THE ROYAL MEDICAL DONOR.

THE speech of the Marquis of Lansdowne in the House of Lords will be received with a feeling of interest not only by the medical officers of the Army but by the whole of the medical profession. It is the announcement of the conclusion of a conflict that has been waged for many years—a certain amount of acrimony for years; it is the announcement of a victory for the medical profession, a victory in the teeth of the most strenuous opposition that the War Office, with all its cast iron prejudices, was able to offer.

Lord LANSDOWNE's kindly and appreciative words will long be treasured, and it is with the most thankful feelings that we record them here.

"The army is proud," said Lord LANSDOWNE, "that it contains a number of officers who belong to the medical profession, but who are none the less soldiers in the fullest sense of the word, wearing the QUEEN'S uniform, holding her commission, ready to take their share—aye, and more than their share—of the risks and hardships of warfare. We are determined that there shall be no failure, either in theory or in practice, to treat them with the respect to which they are entitled."

Most gratifying of all it is to find that the title "Royal" is to be granted, this emanates entirely from, and can only be given by Her Majesty, and that it should be granted, proves that the just grievances of medical officers and their repeated cries for due recognition, have reached and been acknowledged by the QUEEN herself.

Other things may have been wrong from obstinate and unwilling officials, but this last is a spontaneous gift, a Royal gift, coming from Royalty itself, it is therefore a priceless gem, an acknowledgment of worth and merit, and as such we give our hearty congratulations to the officers who, in the future as in the past, will show themselves not unworthy to bear it.

TO KEEP OUT THE PLAGUE.

MR. R. T. GREEN, C.S., the Chairman of the Calcutta Municipality, has issued the following Plague Circular:—

"The attention of all Ward Committees is drawn to the following points which should be impressed on house-owners and occupiers within their jurisdiction:

1. The necessity of keeping all premises free from filth of all kinds and getting rid of accumulations of rubbish within premises.

2. The advisability of white-washing all rooms and passages.

3. All privies should be cleaned at least twice a day, and all drains flushed and master-traps cleaned periodically.

4. In order to assist the Conservancy Department house-owners and occupiers should be prohibited from throwing sweeping into the streets. The refuse should be stored ready for removal in baskets placed outside the premises which can be emptied into the conservancy carts during their daily rounds. The Chairman places great stress on having these measures speedily carried out.

5. All house-owners should be invited to set rat-traps within their houses and do their best to kill as many as possible.

6. Cases of ill-kept latrines and pail-depôts, offensive urinals and privies, should be promptly brought to the notice of the Chief Engineer.

7. Hide-godowns in popinies quarters and other public nuisances, and all unhealthy bastees should be reported to the Chief Engineer who will deal with them as far as possible.

8. Guala busties and cow-sheds, which prove a nuisance to the neighbourhood, should be reported to the Chief Engineer for the Chairman's order."

THE BRITISH MEDICAL JOURNAL ON THE NEW CALCUTTA GENERAL HOSPITAL.

A **NOVEL** feature in the scheme of the new hospital, and one which will undoubtedly add immensely to the comfort of the patients, is its ventilation during the hot and rainy seasons by cold and dried air. The proposal, which will bring about an entirely new arrangement for hospitals in the East, emanated from Brigade-Surgeon-Lieutenant-Colonel OSBORNE. Like most new ideas, it has met with opposition, though the advantages seem sufficiently obvious. During the hot and rainy seasons Calcutta has a temperature varying from 85° to 95° F., and a humidity which frequently reaches 90 per cent. Both are subject to great vicissitudes due to sudden storms of wind and rain. Dr. OSBORNE proposes to establish a uniform temperature in the wards of from 75° to 80°, and a humidity reduced to about 60 per cent, as a necessary part of the process of cooling the air. The relief which this change will give to the outaneous and exhausted nervous systems will be appreciated by those who have experienced the muggy heat of Calcutta at those seasons. As the cool, dry air is to be passed through screens of cotton wool there will be no mosquitoes, and accordingly no necessity for punkahs and mosquito curtains. The advantages are that patients will secure quiet rest at night, and will not lie bathed in perspiration covered with prickly heat, made subject to the chills to which punkahs and sudden changes in temperature render them liable. The cases which will benefit most will be conditions of exhaustion, whether from climate or disease, cases of Bright's disease, and phthisis, for which the climate of Calcutta is particularly unsuitable.

HOW THE CHINESE PREDICT SEX.

SAYS the *Medical Age*.—"Now that the predetermination of sex is to be made possible, it may not be uninteresting to learn the methods whereby the Chinese predict the sex of their offspring. These have recently been enumerated by a French writer. He tells us that when the mother's abdomen is round and prominent, so that it jolts her in her movements, the child will be a girl; whereas if the uterine enlargement be upward, it will be a boy. Nature is not gallant, for even in the uterus the female occupies an inferior position.

"A fresh color of the skin, with more or less pigmentation, especially about the areola, and little change in the visage, betokens a daughter, the opposite conditions indicate a boy. Violent movement of the fetal extremities indicate a little lady.

"If after the seventh month the right hand of the fetus can be found on the mother's right side, a boy will arrive. This is a subtle method of diagnosis, remarks our author, as those will know who have held the hand of a young lady in the dark and tried to guess whether or not it is the hand nearest the heart.

"In a like manner the arithmetical methods of the Chinese are peculiar. If the second figure in the age of the mother and the number of the month of probable conception be both even or both odd, then the child will be male—if one is odd and the other even, then a little Chinawoman will appear. These conclusions have, as this observer says, an air of *Chinoiserie* about them, though they are not more grotesque than some of the explanations whereby the occidental mind has sought to elucidate this matter.

A SUCCESSFUL JEWISH LADY DOCTOR.

THE Jewish community of Calcutta has reason to be proud of its first Lady Doctor—Miss RACHEL COHEN, M.B., F.R.C.S. (Dublin)—who is at present qualifying for the degree of Doctor, and hopes to be back in Calcutta to practise among

her people in April next. Miss COHEN's collegiate career has been one of exceptional brilliancy. Receiving her rudiments in the Calcutta Jewish Girls' School, she passed the Entrance and First Arts Examinations of the Calcutta University with honors, and then entered the Medical College for the usual five years' course. Her singular aptitude for the profession she had chosen was soon made manifest, and before she left she was a prizewoman of high achievement. She first gained Sir GEORGE KING's Gold Medal for Botany in open competition, and passed the M. B. Examination in the First Division. Her next honor was Lady ELGIN's Jubilee scholarship of £100, tenable for two years. With these credentials she sought the "Athenae of Scotland," and in the famous medical school of Edinburgh in no way belied her Indian promise. After a sound preparation she passed over to Dublin, where she has just succeeded in becoming a Fellow of the Royal College of Surgeons, and where she intends sitting for the degree of Doctor. The "woman of Israel" may well rejoice over such phenomenal success obtained by one of them on hitherto unbroken ground, and we believe that Miss COHEN will soon find many of her sisters follow her excellent example, with, we trust, equally satisfactory results.

CLINICAL REPORTS IN INDIA.

WE would remind our readers that they owe the *Record* and each other a distinct duty in the matter of sending us clinical reports for publication. India has an unwholesome reputation of being slow in literary productions. Now it is a mistake to blame India, let us pin the fault on to the right sheet. It is the doctors and not the country who are to blame. If every reader of the *Record* would decide to write an original article, or a clinical report even once a year, we should have enough matter to print *ten daily issues* of the *Record*. It is simply a question of arithmetic arriving at these figures. Now the *Record* is a fortnightly and it is a very much read journal, for though it has a circulation of 3,000 copies, it is probably read by over 10,000 medical men as well as laymen. It does seem strange that out of this large number of medical men and medical women, not more than three in each thousand bother their heads to write up clinical reports. And yet India affords one of the richest fields for clinical experience. It is a disgrace to medical science and medical education in this country, that India's large hospitals teeming with cases of intense clinical interest, cannot find men to write up reports of them for publication. Medical practitioners all over the country have a fund of experience well worth recording, yet they allow all this valuable educative material to go to waste. It is a sad comment on the literary energy of medical men in India to have this dearth of clinical recording so strongly and yet so necessarily deprecated. We sincerely trust the local profession will make an immediate effort to remove this reproach, and that each reader of the *Record* will try to send in a clinical report or an original article for publication in his own journal.

THE FUTURE POSITION OF STATE MEDICINE.

THE following extract from an address by Dr. SEYMOUR SCOTT BISHOP appears to be applicable to some other countries than the United States.—

"When will the people of America awaken to their own most vital interests, and dedicate a government bureau, with a medical head, to the cause of disease-prevention, State medicine and higher education? We are blessed with a department of agriculture that predicts the weather; a department of war that relieves us of our surplus millions; a department of law that really fights the nation's battles. The time must come when State medicine shall be represented in the National Government, to protect against invasive

to prevent disease and to safeguard the nation's health. Our local physicians, however, are not yet ready to undertake such a department of State.

But until the Government of the United States recognizes the vast possibilities of State medicine to conserve the health and vigor of the nation, and to save the great waste of human life that modern scientific research has rendered preventable, can it lay claim to being abreast of the times and the first of the nations of the earth."

THE BIRTHDAY HONORS LIST.

Decorations for the "Profession." (London Gazette)

To be Companion of the Bath.—Surgeon-Major-General Robert Harvey

To be Knight Commander of St. Michael and St. George.—Surgeon-Colonel Rogers, Military Commissioner in Egypt.

To be Commander of the Bath.—Surgeon-Colonel Thomson, Tirah Campaign.

To be Companions of the Bath.—Surgeon-Colonels Townsend, Davis and Saunders, Tirah Campaign.

(*Indian Gazette.*)

To be Commander of the Indian Empire.—Brigade-Surgeon Lieutenant-Colonel Bramfoot, Medical College, Madras.

To be Khan Bahadur.—Assistant Surgeon Asad Ali Khan, Bengal.

To be Rai Bahadur.—Bahadur Surji Kumar Sarbadhikari, Medical Practitioner, Calcutta.

Distinguished Service Order, North-West Frontier Campaign.—Surgeon-Colonel Swayne, A.M.S.; Surgeon-Captain Goodwin, A.M.S.; Surgeon-Major Shearer, I.M.S.; Surgeon-Captain Fisher, I.M.S.; Surgeon-Captain Selby, I.M.S., Surgeon-Lieutenant Hugo, I.M.S.

METEOROLOGY AND INFECTIOUS DISEASES.

HERR J. RUHMANN (*Münchener Medizinische Wochenschrift*) maintains that altogether apart from personal predisposition, meteorological conditions influence the occurrence of infectious diseases. A consideration of the facts shows us that some diseases are most prevalent in summer and some in winter, amongst the latter are diseases of the lungs, influenza, diphtheria, measles and scarlet fever. The factor upon which the prevalence of these diseases essentially depends is *sunshine* and especially the ultra-violet rays which form the chemically active portion of it.

For a series of years the amount of sunshine has been registered at a number of meteorological stations, and a comparison of their data with the prevalence of influenza establishes the law that in the months with least sunshine there was most influenza and vice versa. The same law, but in a manner less marked, holds for the other chief diseases, also for the number of admissions for tuberculosis into the Berlin Hospitals.

BABY INCUBATORS.

GORDON STABLES, M.D., R.N., writes—"Of all inventions ever brought before the public, I think the baby incubator the most cruel and selfish. Poor little infants reared thus are bound to be a misery to themselves throughout life, and if ever they live to be married and have children, these will be weaker and more wretched than themselves. They say that on an island in the Gulf of California there lives a mysterious race of Indians who are the healthiest people and the greatest athletes in the world. No one is allowed into the interior, however. Some years ago, they destroyed all their women and supported an entirely new race. The experiment is said to have been most successful. I cannot recommend it, however. Well, these men in the water are almost like fish, and

the women, as a rule, of kitchen maids who are allowed on the shore. M.M.—This is not a healthy race, but of having an incubator they would be healthy or less intelligent children. Here they live with women. Again, no one is allowed to live beyond a certain age.

ANGLO-INDIAN ASSOCIATION.

We have before us the Report of the Anglo-Indian Association of Madras or Southern India for 1897. It is a volume of excellent work, of brave and steady perseverance and of victory over many depressing obstacles to success. Madras deserves immense credit for the skillful manner in which her Association carries on its fight for its rapidly growing clientele, and we have great pleasure in commending the skill and enthusiasm of our brethren in Madras to the appreciation of our sister Associations throughout the country. The Madras Association has a most successfully and ably conducted weekly newspaper of its own, a journal that is as well edited as any magazine in India. We heartily congratulate our Anglo-Indian comrades in the Southern Presidency, and as cordially wish them and their flourishing newspaper, *The Eastern Guardian*, many years of extended progress and unlimited prosperity.

FRENCH ARMY MEDICAL STAFF.

THE Chamber of Deputies has adopted, without discussion, a proposal to increase the medical staff from 1,800 to 1,487 as follows:—

Old Strength.	New Strength.
1 Medical Inspector-General	1
9 Medical Inspectors	11
45 Principal Medical Officers, 1st class	45
45 " " " 2nd	60
320 Surgeon-Majors, 1st class	340
480 " " " 2nd	500
300 " " " aide, 1st class	400
100 " " " 2nd	50
... " " " cadets	50
1,800	1,487

The titles in the French Army appear to be very simple.

THE LARGEST-HEARTED MAN IN THE WORLD.

EDWARD LEWIS, of Chicago, is, in a literal sense, the largest-hearted man in the world; and to this enviable distinction he adds that of possessing a heart which is as musical as it is large. The beating of his heart is distinctly audible at a distance of several yards, and it emits sounds which are described as distinctly musical.

This remarkable organ has lately been photographed by means of the X-rays, and is found to be nearly three times the usual size, while it has an expansion of 3in. On the left side it extends 3in. beyond the limit of the normal heart; and on the right side it reaches to the ribs. LEWIS has for some years been an object of study to the leading physicians and surgeons of the world, who consider him to be the greatest physical enigma living.

DEATH CERTIFICATES.

A MATTER to which attention has been drawn before is the granting of death certificates by unqualified men. There are a number of so-called doctors who, though they have received some training, do not possess a diploma, and in several cases they are called in after death and asked for a certificate which they light-heartedly give, and which is accepted at the burning place or Mahomedan burial ground. It is felt that, owing to these irresponsible practitioners, a large number of plague cases do not come to light. The

...of affairs is that...
...the... It is...
...the... or... before its final...
...the... of... The Govern-
...declined to... though it
...the Calcutta Health Officer himself, as they
...very... that it would... of the caste
...of the people and would... be strongly
...by them.

THE DANGERS OF FALSE TEETH.

An inquest was recently held by the city coroner touching the death of a grocer's assistant aged thirty years. The deceased wore false teeth attached to a vulcanite suction plate and fastened to his natural teeth by wires. He was in the habit of sleeping with the false teeth in his mouth. On the morning of 15th March, the deceased unfortunately swallowed the false teeth during sleep. He was taken to the Royal Southern Hospital when the teeth were felt to be impacted at the junction of the pharynx with the oesophagus on the left side of the larynx. As it was found impossible to remove the teeth by manipulation, they were eventually withdrawn through an artificial aperture made in the neck. However, the unfortunate man succumbed a week later, septicæmia having supervened.

MADRAS HEALTH OFFICERSHIP.

In connection with the appointment of Surgeon-Lieutenant J. W. CORNWALL as Health Officer of the City of Madras, the Government of India has enquired of the local Government whether it is intended that that appointment should in future be reserved for an officer of the Indian Medical Service, in which case it would be necessary to request the Secretary of State to increase the cadre of that service, as the appointment is not at present included therein. If it is not the intention of the Government of Madras to reserve the appointment for an officer of the Indian Medical Service, then Surgeon-Lieutenant CORNWALL will be seconded from military duty while he holds the appointment, provided his tenure thereof is expected to last more than a year.

A CENTENARIAN'S MODE OF LIVING.

THERE is at present in Auxin, France, a centenarian, who enjoys such excellent health that he does not despair of reaching the age of 127 years. M. JEAN BAPTISTE DUBOIS—that is his name—pretends to know the art of keeping well, and his doctor agrees that his mode of living suits him admirably. When he rises every morning he smokes a pipe. This is followed by a dish of milk soup. He dines at midday, drinks two glasses of wine, and takes his coffee without sugar. At supper he drinks more wine, and finishes the evening on *famille*. His hobby is gardening, and he varies it by rocking his great grand-daughter in her cradle and singing nursery songs.

THE HEALTH OFFICER AND INOCULATION IN CALCUTTA.

We quote from the *Englishman*:—"Dr. COOK's time was fully occupied on Saturday, the 21st May, in operating on about 250 members of Mahomedan families in Kitterabagan Lane. All these people volunteered themselves to be inoculated, and this is the largest number of operations that Dr. COOK has performed in one day since the commencement of the plague. Dr. (Miss) CHRISTIE operated on all the women. Two hundred more Mahomedians of the same locality have offered to be inoculated. The family priest of the Serahar family, Pandit Jagg Chander Vidyashankar, was inoculated yesterday, with 12 others. Up to date 715 persons have been inoculated. The next of now

THE DIVINE HEALER ON TOP.

SAYS the *New York Medical Record*:—"The Kansas State Board of Health recently applied to the attorney-general for a decision concerning the enforcing of the medical-practice law in that State. The legal luminary cogitated for a while, and then delivered the opinion that the magnetic healers and the hypnotists and all the other quacks except divine healers can be prosecuted, but adds that the divine healers claim their power to come from Jehovah and that, as he understands it, the rights and privileges of Jehovah can in no way be regulated or restricted by the statutes of Kansas.

SUCCESSFUL INDIAN STUDENTS.

At the quarterly examinations of the Royal College of Physicians and Surgeons of Edinburgh, we notice the following Indian students who have passed successfully:—

1st examination, five years' course.—R. Chisholm, Assam; A. L. Fielding, Poona, and J. K. S. Bhagvatinhji, Gondal. *2nd examination, five years' course.*—J. B. Swinden, India; and G. H. Umar, India.

Final examination.—C. A. Spooner, Bombay; M. Bant, India; Frances H. A. Bailey, Punjab; A. J. Laurie, Allahabad; and V. H. Roberts, Madras.

FOR PATRIOTIC ANGLO-INDIANS.

"ENGLAND, dear England, our fathers before us
Bled for thy freedom and died for thy fame.
England, dear England our mothers who bore us
Left us their memory entwined with their name.
Ours be the glory to add to the story
Whenever, wherever thy Flag is unfurled.
If great we've received thee still greater we'll leave thee,
England, dear England, the QUEEN of the World."

CERTIFICATES OF INOCULATION.

THE Calcutta Health Office is now issuing certificates to persons who have been inoculated, bearing name, age, caste, sex, address and signature. At the foot of the card a square space is reserved for the thumb mark of the person to whom it is issued. The introduction of these certificates is expected to restore confidence to the minds of the people, and it will at the same time enable them to frustrate the exactions of imposters who go about personating plague officers.

UNEMPLOYED MEDICAL MEN AND WOMEN WITH BRITISH QUALIFICATIONS.

The Council of the Indian Medical Association will be glad to receive and to register for Government employment the names of medical men and medical women, who are desirous of taking up work under Government. Such lists will be forwarded to the Government of India by the Council of the Indian Medical Association.

SHORT ITEMS.

Speaking to the Anglo-Indians of Madras, Mr. President Ryan said:—Do you remember the poet Longfellow's description of the Village Blacksmith.

"Tolling, rejoicing, sorrowing, onward through life he goes. Each morning sees some task begun, each evening sees its close.

Something attempted, something done, has earned his night's repose."

What are you doing brother for the advancement of the Anglo-Indian Cause in India?

A newspaper proprietor was recently sued for damages by a patent-medicine man for an error which was made in printing a testimonial. By the omission of a comma the testimonial was made to read thus: "I now find myself cured, after being brought to the very gates of death by having taken only five bottles of your medicine." (A comma was omitted after death).

We heartily congratulate Surgeon-Major General Robert Harvey, M.D., F.R.C.P., D.S.O., Director-General, Indian Medical Service, on the distinction of a Companionship of the Bath, so fitly conferred on him by Her Majesty the Queen. Dr. Harvey's recent work on the frontier worthily entitles him to a position in this select order. Let us hope a Knighthood is soon to follow.

Dr. Hosack has arrived in Calcutta from Bombay, and has been placed on plague duty in charge of No. 4 Division. Dr. Bannerman, the Deputy Sanitary Commissioner of Madras, who has been specially deputed for plague duty in Bengal by the Government of India, will, it is expected, be attached to the office of the Sanitary Commissioner of Bengal for duty in the plague districts.

The *Journal of the American Medical Association* tells us that a prominent New York physician was invited to be present at the physiology class of a well-known girl's college where the instructress used a cat for the purpose of demonstrating the uterus and ovaries. The class dismissed, imagine the doctor's astonishment to discover that the cadaver used for the lecture was that of a "tom cat."

The latest discovery about kissing is that instead of being a menace to health, the act of kissing involves only an exchange of microbes that are health-giving, and kissing is therefore an excellent method of administering a microbe tonic of great value in aiding digestion. So says the *Philadelphia Inquirer*.

Professor Charcot had certainly as good an opportunity to judge of the value of hypnotism as any physician of modern times, yet as the result of his extensive researches he arrived at the conclusion that not more than one person in a hundred thousand would be likely to be benefited by the application of hypnotism in case of disease.

It is notified that the Governor-General in Council is pleased to prohibit the bringing of used apparel and bedding (except when wanted as the personal baggage of travellers), rags and waste paper from Calcutta into any part of British India.

The Autumn Congress of the Sanitary Institute will be held this year in Birmingham, under the Presidency of Sir Joseph Fayrer, Bart., K.C.S.I., M.D., F.R.C.P., F.R.C.S., LL.D., F.R.S., commencing on 27th September. The Council hope that all the members will endeavour to make the Congress of the Institute thoroughly successful.

A woman named M'Grath, residing at Tallow, co. Waterford, Ireland, gave birth to four daughters on the 28th of March. Application was made for the Queen's bounty, and Sir Arthur Bigge, keeper of Her Majesty's privy purse, forwarded a cheque for £4 with a request to be informed as to the health of Mrs. M'Grath's infant daughters.

The degree of M. D. has been conferred upon Dr. Dyanat Rai, the popular private medical practitioner of Ludhiana and Editor of the *Punjab Medical Journal*, by the Chicago University for writing two original articles on cholera and pneumonia.

The human heart is 6in. in length, 4in. in diameter, and beats on an average seventy times per minute, 4,200 an hour, 100,800 times a day, and 36,792,000 times in the course of the year, so that the heart of an ordinary man eighty years of age has beaten 3,000,000,000 times.

To estimate acetone in urine, Mallat (*Nouveau Remedies*) distils the urine to a fourth of it, and after rendering it alkaline, treats the distillate with solution of iodine. The amount of acetone is determined by the amount of iodoform precipitated.

Surgeon-Lieutenant-Colonel A. J. Sturmer has been appointed to succeed Dr. Brankfoot as Superintendent of the Government Maternity Hospital. Surgeon-Lieutenant-Colonel Walker, who succeeds him in the 4th District, has been granted eighteen months' furlough.

It is notified by the Government of Bengal that the importation from Bombay and Karachi of butter and victuals in general, is temporarily prohibited, and also the importation of rags, raw wool, hair, hides and furs coming from or transhipped at those two ports.

The post of Principal Medical Officer, Her Majesty's Forces in India, will fall vacant on 1st December, when Surgeon-Major-General Gore has to vacate on attaining sixty years of age. Surgeon-Colonel W. Taylor will probably receive the appointment.

Of the seven great physicians, of what has been called the "latter Victorian Era,"—namely Sir William Jenner, Sir William Gull, Sir Richard Quain, Sir Andrew Clark, Sir Spencer Wells, Sir Oscar Clayton, and Sir James Paget—only two, the first and last-named, now survive.

The health of Meerut has been very bad of late. After epidemics of influenza and fever, enteric, that scourge of the cantonment, has been playing havoc with the Connaught Rangers, who have lost several men. All the bazars have been placed out of bounds in consequence.

Dr. Alexander Britto, one of the leading members of the Portuguese community in Bombay, who has for some considerable time been largely associated with plague operations, was married, on Monday morning, at the Church of Our Lady of Rosary, Masagon, to Miss Ernestine Soares.

Robert Maclean has arrived at Calcutta from Bombay and has been started on plague duty. Dr. H. B. Roy, the Health Officer of Calcutta, has also arrived at Calcutta to learn the progress of inoculation from Dr. V. C.

Surgeon-Major Dehnen, Civil Surgeon, Dhulak, takes charge of the Medical Store Department, Punjab Command, during the absence of Brigade-Surgeon, Lieutenant-Colonel Calthrop, on leave.

In an operation for mesenteric fibrosis, Dr. F. J. Shepherd of Montreal had to excise 8 feet of the bowel. This is the longest piece of bowel removed from a human subject, and the man made a marvellously quick recovery.

The Punjab Government has sanctioned a plague allowance of twenty per cent on pay to all civil officers on special duty in the infected area, and one month's privilege leave for every five months spent on plague duty.

It transpired at the inquest that Assistant Surgeon C. J. Beesborne committed suicide at the Lucknow Railway Station because he had been reduced departmentally. The unfortunate officer was about to be married.

There is no plant, says an English weekly, which animals so detest as the castor-oil plant. A goat will starve rather than eat it, and those destroyers of everything green, the locust and army worm, will not touch it.

Mr. Sydney Hinde, who has been one of the medical officers at Mombasa for the last two or three years, has been selected by the Consul-General of Zanzibar to be the new District Officer of Masailand.

The Catholic authorities at Rome have rendered a decision forbidding the practice of artificial impregnation, devised by Marion Sims. The reasons for this prohibition are not stated in the decree.

Miss Cruickshank, sister of the late Dr. Cruickshank, has given £15,000 to the University of Aberdeen to found a botanical garden in memory of her brother.

Dr. Horace Castellote, F.R.C.P., F.R.S., has been awarded the Imperial Gold Medal on account of his conspicuous services in connection with the bubonic plague in Bombay.

A prize of \$10,000 is offered by the Belgian Government to any one who invents a chemical that will replace phosphorus in the making of lucifer matches.

A Melbourne chemist subpoenaed to give evidence about a prescription in the Divorce Court, pleaded privilege, but his claim was not allowed.

The Government of Bengal is appealing a second time to Simla regarding the question of making adequate provision for bacteriological research in India.

Oxide of zinc, used on a piece of thick spongy sole leather and briskly rubbed, imparts a high polish to surgical instruments.

Dr. Shumard's curative serum is gaining the confidence of the Medical Faculty in Karachi by its beneficial results on the patients of the Vishwandas Hospital.

Surgeon-Captain Pilgrim is appointed Superintendent of the General Hospital at Calcutta vice Mr. Cramble.

To prevent the pestiferous progress of tinea just add a drop of turpentine oil to the ointment.

Surgeon-General Claghorn may not return to India.

Current Medical Literature.

MEDICINE.

Case of Rabies with Prolonged Incubation.

FALKE and ARONIMBAUD give the notes of a case of rabies occurring in a young man, aged twenty years, who died in wild delirium within thirty-six hours after the initial symptoms of the disease appeared. No history of a dog-bite was obtained, and the correct diagnosis, although suspected, was not fully established until after death. Then, in questioning the parents, it transpired that the young man had been bitten in the mouth six months previously. The animal by which the bite was inflicted was found to have rabies, and a child bitten by it was treated at the Pasteur Institute and recovered. The case of the young man is remarkable on account of the long period which elapsed between the slight bite of the dog and the fatal disease of the man. There was no possibility that fear caused the illness, as neither the patient nor the parents suspected its nature until after death had occurred.

In this connection it is interesting to note that FORTVIN says that during 1896, 1,308 persons were treated at the Pasteur Institute of whom 4 died, giving a mortality of 0.3 per cent, and making the total mortality since 1886 a fraction under 1 per cent. Bites in the face gave a larger mortality than wounds of other parts of the body. Since the establishment of the Institute 3,096 foreigners and 15,849 natives have been treated in the Paris institution. It will thus be seen that the number of persons treated last year is considerably below the average for the ten years in which the Institute has been open. This is due, no doubt, to the establishment of similar institutions in other cities rather than to the fact that treatment for rabies is becoming unpopular.—*Med. News*

Treatment of Chronic Articular Rheumatism.

For persons affected with polyarthritides deformans Dr ORT recommends residence in a warm, dry place, such as Ischia or Algiers, which is sheltered from winds and has hot springs convenient for the hydropathic means of treatment which combine hot and cold baths to tone up the system which should also be strengthened by medicines such as iron, quinine, cod liver oil and a generous diet with meat as a foundation, together with eggs, fish, butter, cheese and vegetables, as well as plenty of milk and good drinking water, but alcohol and the carbohydrates should be much restricted, if not altogether excluded, and moral depression avoided; while the case should be carefully watched even long after convalescence and baths, which are useful, if not essential, adjuncts to treatment should be suspended as soon as symptoms of inflammation re-appear. To do good treatment must be prompt enough to meet every stage of the disease. Thus fever must be surmounted by repose in bed, restricted diet and salol, antipyrin, acetanilid, phenacetin, &c., local pains and swellings by morphine injections, Priessnitz compresses, liniments, or salves containing opiates and severe swellings by puncture or by the elastic bandage. When the joints are swollen without much loss of motion or dislocation of the ends of the bones, external treatment, that will favor absorption is indicated, and tincture of iodine by itself or with ichthyol may be used to advantage in hastening absorption.—*N. Y. Med. Rec*

Serum Treatment of Leprosy.

Dr. CARASQUILLA announced to the Academy of Medicine that he had discovered a new method of treating leprosy by infection of an antileprosy serum. He declared that this treatment ameliorated the state of the patient and sometimes even brought about a complete cure. Unfortunately for the victims of this disease the predictions of Dr. CARASQUILLA have not been realized, and the cure announced have been only apparent. The error was entirely anomalous, for leprosy is an affection which advances by successive stages which are often followed by prolonged periods of improvement, sometimes so marked as to seem like cure. If the treatment is given during this stage, one might attribute the cessation of the active symptoms to the remedy employed, but the same improvement would have been noted had there been no intervention. The antileprosy serum of Dr. CARASQUILLA is prepared by injecting serum from the blood of a leprosy

subject into human. It does not seem to possess any really beneficial action upon a subject of leprosy. This result has been shown when a patient submitted for a long time to the action, without any improvement except that which is ordinarily noted in the interval between acute attacks. This discovery has been announced prematurely, but there is no need to lose hope of finding an efficacious serum. However, it is requisite to seek it by other ways and means than those employed by Dr. CARASQUILLA.—*E. Y. Med. Rec.*

Recurrent Hepatic Fever.

For 16 months prior to her disease from choleraemia a woman, *et. 49*, had periodical attacks of biliary pain with fever and rigors, succeeded after a few days by intense jaundice in which the stools varied from normal to putty color but contained no stones. In most of the attacks (some of which were painless) there was no exceptional leucocytosis, and during a crisis rapid enlargement of the liver, which slowly resumed its normal size to 2 fingers' breadth below the ribs and remained 'tender,' but between attacks she was a febrile though still slightly jaundiced.

Necropsy showed the gall bladder atrophied and the liver changes usually consequent on total biliary obstruction, while the common bile duct, which contained colon bacilli, was blocked by a stone. FRIEDEL PICK (*British Medical Journal*) lays great stress on this leucocytosis whose absence in the intervals between the recurrent febrile and colicky attacks in a case of cholelithiasis he thinks sufficient proof of the absence of pyemic or suppurative conditions, and that operation is not contra-indicated. He further explains that the marked diminution in the urea excreted is due not to replacement of urea by ammonia in the urine, as BERNARD imagines, but to decrease in the urine voided and to other urinary changes solely depending on the diminished amount of food and drink consumed.

Cattle Malaria.

CELLI and SANTORI propose the name 'cattle malaria' for a disease, which attacking the foreign but sparing the indigenous cattle of the Campagna, is characterised by fever, enlarged spleen, bloody urine, a rather high mortality and the presence in the red blood corpuscles of not easily cultivatable endoecoparasitic parasites, which may be double or pear-shaped, and which SMITH of Texas named the *Pyronoma* *gambium*.

This disease, which closely resembles human malaria, is most favorably influenced by quinine and strictly confining itself to malarial districts and seasons is communicable from one animal to another of the same kind and race. In severe cases the disease is accompanied by hemoglobinuria—a neither constantly concomitant nor frequent symptom—and is identical with—(1) the Texas fever of SMITH, (2) the cattle hemoglobinuria of BABES in Roumania, and of KROGUS in Finland, and (3) the cattle hematimuria of SANFELICE and LOI in Sardinia.—*Brit. Med. Jour.*

Nervous Vomiting.

LOOKING at this symptom as a purely functional disorder, produced by disturbance of the central and peripheral nervous system without external irritation or anatomic lesion, IMBELL notes that, occurring without any over-exertion, it is independent of the quality or quantity of the ingested food, and often absent after a difficultly digestible meal and present when only suitable food has been eaten. He suggests treatment being directed to the strengthening of the body, and found that menthol $\frac{1}{4}$ grain and sedibionarb gr. viii., given three times a day, was very beneficial, though in severe cases suppositories of belladonna grain $\frac{1}{2}$ and codain grain $\frac{1}{2}$ had also to be given. Castor oil, the bismuth salts and large doses of alkalies are useful, and in the painful form papaverin combined with code renders grand service. Painting the pharynx with 10th per cent. cocaine solution cures some cases.—*Med. News.*

SURGERY.

Splenectomy for Rupture without External Wound.

Is very strongly advised by Mr. C. A. BALLANCE, M.A., F.R.C.S., as the rhythmic contraction and expansion of the spleen clearly add to the difficulties and dangers surrounding the arrestment of hemorrhage from it by any other plan than that of that organ when extensively injured, and proof of such is obtained by a history of violence and a large *fluid* dulness in the left flank. As a rule, the shock is very severe at first, and however great the initial collapse may be in slight, splenic ruptures, the bleeding may be quickly and permanently arrested by nature's method of coagulation, but when the injury is severe, the bleeding, which at first ceases, will recommence as soon as the patient has rallied, or a later period, and the remarkable feature of the bleeding, whether it be of the reactionary or secondary type, is its slowness. A large amount of blood may be lost at once into the peritoneal cavity, or the evidence of free fluid in the abdomen may not be forthcoming in 24 hours; but as in either case a patient with a belly full of extravasated blood is in immediate danger of death the operation *must* be completed in the shortest time possible and no method so certain or so reliable as extirpation of the ruptured spleen, yet whatever the plan of treatment adopted after extirpation, the patient will probably remain in a critical state for 14 days, when compensation for the abolished function by the spleen will take place slowly but surely and *pari passu* with the completion of the compensatory changes perfect health will be regained.—*Practitioner.*

Radical Cure of Hernia in Infancy.

FROELICH, at a recent session of the Congrès Français de Chirurgie, discussed the indications of the radical cure of inguinal hernia in infants, and described his method of operating in such cases. This surgeon holds that in children under 2 years of age inguinal hernia will usually be cured by the use of a suitable truss. Beyond this age spontaneous cure is an exceptional event, and an operation for radical cure is therefore indicated. In early life, if a hernia increases in size in spite of the application of a good truss, an operation should be performed, however young may be the subject. Such treatment, which is almost quite free from risk, will not only relieve the child of a permanent infirmity, but also obviate the physiological failure likely to be caused by a large hernia. The mortality, it is stated, is about 4 per cent and the relapses 6 per cent. The operation performed by FROELICH consists in simple ligation of the neck of the sac, which is retained intact and without any dissection from the scrotal tissues, and in careful suture of the abdominal wall. In the discussion on this paper BROCA expressed his concurrence with regard to the indications for surgical treatment in young subjects, but at the same time held that it was advisable to deal more freely with the sac. In children as in adults there is no risk of peritonitis, and therefore, except with regard to the saving of time, no advantage can be gained by refraining from opening and removing the sac.—*Brit. Med. Jour.*

After-treatment in Cases of Abdominal Section.

To combat shock, BODOR, of Budapest, besides enemata or infusions of salt, employs subcutaneous injections of strychnine, not exceeding the dose of fifteen one-hundredths of a grain. Opium and morphine, he thinks, should not be used. Through the day on which the operation has been performed he gives the patient teaspoonful doses of very hot water (at 104° F.), which, he says, has a favorable action on the mucous

membranes of the stomach, besides increasing the bulk of the gastric contents and thus facilitating the act of vomiting. On the second day the patient is allowed bouillon, beef tea, and tea with milk; on the third day, soup with egg, scraped raw meat, and soft-boiled eggs. This is to excite intestinal peristalsis. In eight or ten hours after the operation a rectal tube is passed through the anus, and this is repeated every four hours, for the removal of flatus. He considers it irrational to give morrels of ice to allay thirst; he prefers the drinking of warm water and the ingestion of salt. To prevent septic peritonitis, the occasional effect of migration of the *Bacterium coli*, he gives calomel before the operation. To avoid ventral hernia, he makes the incision along the middle of one of the recti abdominales muscles.—*N. Y. Med. Jour.*

Mortality of Tetanus with and without Antitoxin.

OWENS and PORTER, who report three fatal cases—two treated with antitoxin—and have carefully analyzed all the published cases in which the serum had been used, are of opinion that those cases of tetanus in whom symptoms appear before the sixth day will die in spite of any antitoxin treatment; but those in whom the symptoms are delayed beyond the second week will invariably recover, whether treated symptomatically or with tetanus antitoxin. The Medical Bureau of the Columbian Exposition (*Medical News*) who were singularly lucky with 202 cases of ugly punctures with rusty nails, not one of whom developed tetanus, declare it is better to prevent the affection than to place dependence on antitoxin serum after tetanus has developed. Their procedure was to (1) irrigate freely with sublimate 1—1,000 solution. (2) Trim the edges of the wound and (3) after swabbing it with 95 per cent., carbolic acid solution to (4) drain it if necessary, (5) dress it antiseptically and (6) advise rest.—*Jour. Amer. Med. Assoc.*

Uretero-Ureteral Anastomosis.

1. URETERO-URETERAL anastomosis is a perfectly feasible procedure. 2. Uretero-ureteral anastomosis, whenever possible, is far preferable to any other form of ureteral grafting, to nephrectomy, and to ligation of the ureter. 3. It should be done preferably by lateral implantation, or by oblique end-to-end anastomosis, though the transverse end-to-end or the simple end-to-end method may be safely employed. 4. The constrictions of the calibre of the ureter do not usually follow attempts at entering in closure of complete transverse section of the duct. 5. Nephrectomy for transverse injury of the ureter *per se*, is an unjustifiable operation. 6. Simple ligation of the ureter, to produce extinction of the functions of the kidney, is too uncertain to justify its practice. 7. Drainage is not necessary if the wound be perfectly closed and the tissues throughout are aseptic.—*N. Y. Med. Rec.*

Better than Skin Grafting.

THE following prescription will be found invaluable to restore the skin, where it has been destroyed by disease, in lieu of the painful and troublesome operation of skin grafting:—

R. Antifibrine ... 3 grains.
Vaselin ... 1 ounce.

M. To be thoroughly rubbed up and applied topically.

I had a case of phlegmonous erysipelas of leg, which was bared of nearly all the flesh from hip to foot. After the flesh was restored, we were considering the subject of skin grafting, but just at that time, I noticed in the *Brief* this prescription, and was thereby saved all further trouble in the case. It answered the purpose.

I do not know whose prescription it was, or would give him merited honor.—E. B. HAMPTON, M.D., in the *Med. Brief*.

OBSTETRICS AND GYNECOLOGY.

Technique of Subcutaneous Symphysectomy.

SHOUBAL tail dilatation of the cervix, if possible, without risk to the child. Have the urethra and bladder held to one side with a sound. Make the initial incision a little above the sub-pubic arch and under the elevated clitoris. Introduce the left index finger within the vagina against the posterior groove or ridge of the joint, up to the top. Pass a narrow tenotomy knife with the point close to the joint, up to within a half-inch of the top and under the overlying soft tissues. Substitute a probe-pointed bistoury and meet the left index finger with the probe over the top of the joint and work the blade through the joint downward, until separation is felt by the posterior finger. Have an assistant press the mouth of the wound and the tissues lying over the joint with a small piece of gauze. Deliver with forceps, if possible, and refrain from suprapubic pressure aiming to deliver the head through the cervix without drawing the latter down below the symphysis. Hold the bladder well to one side while pressing the pubic bones together. Pass a small strip of gauze into the prepubic wound and another against the cervix after irrigating, leaving both pieces exposed for easy removal, having refrained from stitching cervix or perineum. Introduce a soft-rubber retention catheter into the bladder, and leave it until sure the patient can voluntarily micturate. Dress the vulva with gauze and strap the joint with adhesive strips. Remove all the gauze in thirty-six hours and irrigate vulva and vagina twice a day, keeping the vulva carefully dressed between times.—AYERS in *N. Y. Med. Rec.*

Twin Bearing and Prolificacy.

BEFORE the Edinburgh Obstetrical Society, at the December meeting, the above subject was under discussion. Dr. J. W. BALLANTYNE read a paper on the "Caustion of Twins as Illustrated by some Clinical Histories." After giving the history of several cases he mentioned that of a woman who was one of a family of seventeen, no twins; one of her sisters had had triplets and another twins; she herself had had twenty-two children in eighteen confinements, *etc.*, four times twins and fourteen single births. In all the cases referred to there was good evidence to show that the twins were of the binovular or dichorionic kind. He mentioned the association of twin bearing and prolificacy and deduced that the daughters of a woman who has borne twins are usually highly prolific, and conversely the mothers of twins are usually the daughters of specially prolific women. He mentioned the theory that the ovaries of the twin bearer resemble those of the fetus in the great number of Graafian follicles they contain. Pleural pregnancies result from the simultaneous rupture of several oviducles, and that this is a consequence of the existence of a relatively or absolutely large number of ova in the ovaries. Dr. HAIG FERGUSON mentioned the case of a woman who had seven children; in three years, twice twins and once triplets. Dr. JAMES BUCHAN referred to a mother who had borne thirty-two children; it had been mentioned in an application for life insurance and he had verified the statement.—*Jour. Amer. Med. Assoc.*

Hyperemesis Gravidarum and Salt in Food.

ANTONCHEVITCH sees a strict homology between uncontrollable vomiting of pregnancy, and vomiting from which animals suffer when deprived of salt in their food, being fed on albumen artificially deprived, as much as possible, of potassium and sodium salts. He has, therefore, dieted women suffering from hyperemesis gravidarum by taking care that their food contains at least a full proportion of salts.—*Canadian Prac.*

Comparison of the Duration of the Two Forms of Treatment of Certain Uterine Hemorrhages.

The "pro" and "cons" of these two procedures are then compared by Dr. SATLY in the *British Medical Journal*, 28th February, p. 21.

Curetting.

Hemorrhage will be controlled immediately, but other treatment will be required to cure the case.

An operation for which an anæsthetic may be necessary, or patient may suffer pain necessary to have one or more assistants.

Confinement to bed often necessary.

Case is usually removed by one or two treatments, but the uterus is often not reduced in size; therefore a tendency for the cause of the hemorrhage to recur unless further treatment be given.

In choosing between the two forms of treatment, the author considers that, broadly speaking, a uterus with considerable tone and contractile power will be best dealt with by curetting, while an atonic flabby uterus will respond more readily to galvanism. The more chronic the case, the more is galvanism indicated. Often the two procedures may be profitably combined, the galvanism following the curetting. In detailing the galvanic procedure the author advocates a low amperage—say, fifteen to twenty milliamperes—the positive pole being intrauterine, and the negative electrode of large size being upon the abdomen. Frequency of application, at first every other day, afterwards once or twice a week for some weeks, according to the nature of the case. (An aluminium electrode of such a size as to fill the cavity of the uterus, and come into contact with every part of its surface, has been recommended.)—*Treatment.*

Adhesion of the Female Prepuce.

BACON concludes from his observations and experience that preputial adhesions in the female may produce two different effects. (a) an irritation leading to masturbation and various neuroses; and (b) prevention of development of the glands clitoridis resulting in an ercicism. The reflex nervous centers of the child being less under the control of the inhibitory impulses than in the adult, peripheral irritation gives rise to nervous manifestations in the former which in the latter would have no effect. As preputial adhesions in the female are capable of setting up as grave nervous symptoms as the like condition in the male, BACON is of the opinion that every female child should be examined and the clitoris liberated at the same period that this or circumcision is undertaken in the male—that is, some time immediately following the separation of the navel.—*Med. Age.*

Treatment of Vomiting of Pregnancy.

GRONHOFF is convinced that the condition of nausea and vomiting of pregnant women is due to reflex contracture of the digestive tube; that such contracture is located either at the pylorus and the different portions of the small intestine, or more particularly in the ilioæclic angle of the colon, and that this painful contraction at this angle is a pathognomonic sign of reflex hyperæsthesia of the intestinal canal, of which the morbid symptoms vary from slight pain about the heart to simple nausea or to uncontrollable vomiting. By the slow, light, progressive movements of massage, with the help of the fingers, he is able to cause the passage of gas and liquid through this region with gurgling sounds distinguishable both to the physician and to the patient. Usually two or three sessions of this light massage are sufficient to cause the vomiting to cease altogether, though the treatment may be repeated as often as necessary without fear of ill results. This procedure has been employed by the writer with complete success in a number of obstinate cases.—*Med. News.*

Pathology, Pathogenesis, and Macroscopy.

The Accumbent Accessory Lobe of the Liver.

The pathologic, tumor, and macroscopic changes in the accessory lobe of the liver are described by Dr. C. MARTIN, assisted by Drs. MARTIN, J. W. TAYLOR and J. F. JORDON at the Birmingham Hospital for Women. The tumor, which was of a dark-greenish hue, was microscopically examined by Professor KAUFFMAN, who diagnosed it as an isolated ductless accessory lobe of the liver, presenting great differences of structure in different parts:—(1) Large granular polygonal liver cells separated from each other by bands of vascular connective tissue; (2) masses of broken down degenerated liver cells; (3) masses of granular pigment—remnants probably of broken down liver cells; (4) where liver tissue was absent there were cells (some suspiciously sarcomatous) of all sizes and shapes, confusedly jumbled up in a vascular connective tissue; (5) scattered hemorrhages in degenerating areas appeared as red, soft areas, and (6) in no place was a definite cell-arrangement corresponding to a portal system; (7) the green color was probably due to bile pigment deposited by the abortive liver cells in the lobe; and (8) for some reason not clearly understood, this pedunculated accessory lobe that remained quiescent for several years, became the seat of degenerative changes and interstitial hemorrhage.—*Brit. Med. Jour.*

Muscles of Respiration.

RUDOLPH FICK publishes an original paper on the muscles of respiration. In the first part he refers to the results of other investigators, especially in relation to the intercostal muscles. The last part contains an account of his own investigations. In the observations of other authors the internal intercostal muscles were dissected, and their action determined by direct inspection. In those of FICK all the costal muscles were left intact. He first examined the auxiliary muscles of respiration in the neck, and proved that they were absolutely inactive in normal quiet respiration, and only came into action in isolated, extraordinary, deep, sighing respirations, the result of their action being to elevate the thorax *in toto*. Next the auxiliary muscles of respiration and the diaphragm were paralysed by severing their nerves in the neck, and the action of the abdominal muscles eliminated by dividing them. It was then found that the respirations continued in normal rhythmic manner, the difference between inspiration and expiration (apparently active) measured through a tracheal cannula being 80 mm. of water. These experiments, taken in connection with the geometrical deductions contained in the early part of the communication, proved that normal quiet inspiration is the effect of the contraction of the external intercostal and intercartilaginous muscles, and that expiration is effected by the internal intercostal muscles. BERGMAN and REINHARDT, of Stockholm, have arrived at the same results by similar experiments.—*Brit. Med. Jour.*

Food and Antidotes: A New Theory.

THAT the antitoxic function is independent of immunity and after all may be a physical and not a chemical phenomenon, while the true existence of a preservative substance in the serum of vaccinated animals (though yet to be proved), is suggested by the exhaustive experiments of GALTHER and

against various poisons. (1) Animals can acquire immunity against fatal chemical poisons without their serum being antitoxic and (2) they cannot like vertebrates, including animals, produce antitoxins under the influence of repeated non-fatal injections of toxins. (3) Antitoxic antivenomous serum can be used both for the production of passive immunity in man, as well as for the diagnosis of the serum which they oppose. (4) Certain chemical poisons, which destroy or profoundly alter the toxins do not modify the active substance of anti-toxic serum, nor does such active substance alter the toxins when mixed with them *in vitro*, though it appears to exist in the leucocytic protoplasm of vaccinated animals and acts as energetically on the leucocytes of fresh animals as do the antimicrobial sera. (5) Natural or acquired immunity cannot be due to the presence in the serum of a chemical substance since certain substances, such as bouillon and normal serum, with no specific action on toxins or the sera of certain animals vaccinated against various infections or intoxications can, when injected into fresh animals, act preventively as regards other infections or intoxications.—*Brit. Med. Jour.*

Simple Method of Estimating the Toxicity of the Urine.

PELLIGRINI has made a number of experiments which go to show that the amount of potassium indosyl sulphate in the urine is a reliable index of the degree of its toxicity. He recommends the employment of PRIMAVERA's test for this substance, which is as follows: Pour from 4 to 5 c.c.m. of urine into a test tube, and add slowly one-third the volume of pure concentrated sulphuric acid. Cool the mixture by dipping the end of the test tube into cold water. And 1.5 c.c.m. of pure chloroform. Mix thoroughly, and then allow the chloroform to settle to the bottom of the tube. If potassium indosyl sulphate is present in normal quantity, the chloroform has a light-blue tint. When it is present in excessive amount, the chloroform has a deeper blue color proportionate to the excess. Information regarding the degree of toxicity of the urine is of special value in cases of insanity in the causation of many of which auto-intoxication is now known to be a very important factor. PELLIGRINI believes that the increased toxicity of the urine in such cases is chiefly due to abnormal fermentation within the gastro-intestinal tract; it is important, therefore, to correct any disorder of digestion in these patients.—*Brit. Med. Jour.*

Difficulties of Bacteriological Diagnosis of Diphtheria.

Strasberg says that (1) animal inoculation being indispen-
sible in diphtheria (2) microscopic examinations of the colonies developed on serum do not suffice for positive diagnosis since (3) diphtheria is never produced by non-virulent bacilli (saprophytes) which may exactly re-
semble them. Diphtheria morphologically has a quite dis-
tinction from Corynebacterium microbes. He is supported by O.
Friedlander (Cent. Med.) in his contention of the absolute (4)
inoculation of the GUERINIERE character and constant or at-
tributable to it. Diphtheria not passing to non-pathogenic
strains. He also regards the short periods of incubation, which
may be as short as 24 hours, as being a distinctive feature of them
and that of saprophytes, the incubation period for the
latter may extend to 10 days. He also mentions the fact that
diphtheria which turned out to be of the acute and fatal
diphtheria never test. — Cent. Med. Jour.

... ..

Changes in the green and yellow are noticeable, standing and blood purifying, but are not good if the color of order and green water-green, though some purifying are of little food value.

Tomatoes yield higher nerve and muscle food and waste with-
out heat, but they should not be used freely in cold weather,
as they are thinning and cooling, and require more of the higher
nerve and muscle food but do not give any.

Green figs are excellent food, but though they contain nerve and muscle food, heat and waste dried figs are bad for the liver.

Bains are stimulating in proportion to their quality, but prunes, which afford the highest source of heat food and supply heat and waste, are neither warming feeling nor good, for those who suffer from the liver.

Pine kernels give heat and stay and serve as a substitute for bread, while blanched almonds give only the higher brain nerve and muscle food; but walnuts, hazel nuts and Brazil nuts give nerve or brain food, muscle heat and want. — J. B. Health Jour.

Disinfection of Clothes by Heat

For the complete destruction of organisms in the absence of spores, exposure to dry heat at a temperature of 130°C. for at least an hour and a half is necessary. Koon found that spores of anthrax required for their destruction dry heat at 140°C. maintained for three hours. Dry heat acts by conduction, and therefore the temperature of the inner portions of a woollen fabric may be comparatively low, while the outer ones become scorched. To disinfect clothes in stoves and hot ovens is not only injurious but useless.

Moist heat at 60°C. kills all pathogenic organisms when free from spores. 100°C. (moist heat) quickly kills spores of most of the pathogenic bacteria. Saturated steam, when it penetrates into the interstices of a body at a lower temperature than itself, such as a blanket or coat, undergoes condensation into water, then occupying only a very small fraction of its former volume. To fill the vacuum thus formed more steam presses forward in its turn, yielding up its latent heat, and becomes condensed, and so on until the whole mass is penetrated. Steam condensed at 100°C. is the essential point in the disinfection of clothes by this method.

Superheated steam, like dry hot air at the same temperature, is both useless and injurious, for the following reasons: If steam at 100°C. be admitted into a chamber heated up to 115°C., no condensation occurs on the outer layer of the clothes, for the reason that this outer layer has become heated above 100°C., so we get no germicidal action. But when the steam penetrates further into the fabric it meets with a temperature below 100°C. and then condenses; consequently the inside becomes sterilized whilst the outer does not.

Room has found by experiment that exposure to a current of steam at 100°C. was the most satisfactory means of disinfection. Dr. Parsons states that it may be considered to be established that the complete destruction of an object by steam heat at 100°C. for more than one minute is sufficient for thorough disinfection.

The above statement that T-10, say, has will not work. It is slightly misleading. For it is well known that such

a temperature sufficiently high to destroy the germ. The real point is that the dressing will not reach the surface of the stump, but will be absorbed by the

at 100° C., which kills both germs and the dressing. It is maintained sufficiently long.—*Ed. Med. Record.*

Shall Newborn Babies be Washed?

SCHADEE has investigated the effects of bathing new born children, in order to settle the point as to whether the healing of the stump of the cord is influenced by that process. The treatment of the stump was the same in all of the one hundred and fifty cases. It was dressed daily with sterile gauze and dusted with a mixture of one part of salicylic acid and four parts of starch. The healing of the stump and its separation took place in a more satisfactory way in those children who had been bathed. Dry dressings for the stump were found to be much better than oily ones, the fat preventing the proper drying of the cord. The weight of the bathed children increased more rapidly than that of the others, and no cases of eye infection from the water used in bathing the children were noticed.—*Surgical.*

Comparison of Cigarette and Cigar-Smoking.

IN the *Virginia Medical Semi-Monthly*, SOHON discusses the injury received from smoking cigars as compared with that from smoking cigarettes. He emphasizes the harm of smoking before the body is fully developed. Locally, the effect of cigar or pipe-smoking is far worse than that of cigarettes. The cigarette smoker rarely has a chronically inflamed throat, as is invariably the case with cigar smokers. Cigarettes, unless used inordinarily, do not produce a cough. Few singers can smoke cigars, while many of them smoke cigarettes. The difference seems to be in the choice of a profound intoxication at longer intervals or a transient impression which can be repeated oftener. He thinks that one can better judge of the dose of nicotine by the cigarette. He admits, however, that one is more likely to over-indulge in cigarettes on account of the greater satisfaction derived from inhaling.—*Med. News.*

Must Assert Privilege in Time.

REFERRING to the provision of the California code that a licensed physician or surgeon cannot, without the consent of his patient, be examined in any civil action as to any information acquired in attending the patient which was necessary to enable him to prescribe or act for the patient, the supreme court of that State says that the privilege is personal to the patient, and is waived when he calls the physician himself as a witness, or when he permits him to give his testimony without making any objection thereto. If the patient once consents to his testifying, he cannot, after the testimony has been given, revoke the consent, and ask to have it excluded. Such consent may be either implied or expressed further holds the court, in *Lisak vs. Crocker Estate Company*, where it maintains that there was an implied consent when the plaintiff permitted the witness to be examined in full by the defendant without any objection.

Hospitals not Liable for Negligence of Attendants.

IN a decision handed down by Justice COHEN in the Supreme Court he holds that hospitals are not liable for the negligence of attendants so long as it is shown that proper precaution has been exercised in the selection of such attendants by the hospital authorities. The case in which the decision was rendered was a suit brought by Miss ELEAN D. WARD to recover damages from St. Vincent's Hospital for injuries received while she was a pay-patient at that institution. On one occasion she was placed in a bed between the sheets of which had been left a hot-water bag, and her leg was so badly burned by contact with the bag that operative procedures were necessitated. The judge finds that the accident was due to the single careless or thoughtless act of one of the employees of the hospital, and that the plaintiff has no cause for action against that employee, but not against the institution.—*Phil. Med. Jour.*

Therapeutic and Physical Aspects

THE question of ozone is one of the most interesting and important in the history of medicine. It is a powerful antiseptic and the oxygen with which it is saturated is soon absorbed. It is found, however, in distinct quantity in the pure air of the country and, as everybody knows, in sea air. Its occurrence in air is invariably connected with the existence of water generally in motion. Thus the wind blowing over the sea waves or over the waves of a lake, or the air in the immediate neighbourhood of a waterfall or spray contains a notable amount of ozone. Of course ozone must to some extent exert a purifying influence upon the air, but this can only be of importance when the ozone occurs in distinct quantity or when it is being constantly evolved, as over the surface of the sea. Doubtless sea air and mountain air owe their beneficial qualities to their purity which in some measure is due to the action of ozone. This fact has led to the devising of apparatus for the simple and easy production of ozone in hospitals and large buildings. It may not be generally known that a very simple and effectual way of bringing ozone into the house consists in first suspending moist linen sheets in a keen dry wind, and afterwards hanging them up in the house. The air in the room will thus become considerably charged with ozone and its presence will be easily detected by its peculiar smell, while a moistened starch iodide paper will instantly turn blue. Why ozone is accumulated in wet clothes in this way is not quite understood, but it may be due to the rapid passage of the oxygen in air over a large wet surface. It is not improbable that this interesting phenomenon plays an important part in the real hygienic cleansing of our linen articles of clothing. In big laundries when the not quite dry linen is brought in after having been exposed to a cold, dry air for a short time the smell of ozone is almost more than is agreeable.—*Lancet.*

Therapeutic Value of Spleen Extract.

THE *Edinburgh Medical Journal* contains the results of an investigation extending over two years and establishing the therapeutic value of this extract. Briefly, "it aids digestion and nutrition, increases the cutaneous activity, stimulates the glandular activity of the skin, etc." In the first class of cases chronic inertia, mental and physical, after a year's treatment the mental result was nil in a few, slight improvement in a few and recovery in two. The second class included recent cases of insanity due to physical exhaustion and the results were more prompt, first physically than mentally, the majority being improved and some completely restored. The effect on the pulse and temperature, the bowels and urine, is yet to be determined definitely; in some the appetite improved, in more the digestion; the weight curves varied, increase of weight being the rule; in all the women there was increase of haemoglobin and red blood cells with one exception; color and warmth of the skin with softness and elasticity was noted; mentally, exhibition of temper was noted in both sexes, more so in the males. The author had previously used thyroid extract with no success in these mental cases. He believes that "spleen extract, if less phenomenal in its effects than thyroid, is conducive to more lasting results, that it is sweeter, and still more important, exceedingly safe," but much smaller doses are sufficient to produce good results, especially after use of the etherial extract.

Schwimmer, while agreeing that the treatment of the primary symptoms is of great importance, holds that the same medicinal treatment should be applied to the secondary symptoms.

from the fact that the primary symptoms are the same in any disease being played on the activity of the primary symptoms as a guide to the subsequent course of the disease, and holds that all cases should undergo the same medicinal treatment. He points out that the discovery of the organisms of the soft sore and of gonorrhoea has led to no improvement in the therapeutics of those disorders, and considers that the possibility of a bacterial cause for syphilis should not interfere with its present empirical treatment. With regard to the duration of treatment, with which the question of permissibility of marriage is bound up, SCHWIMMER quotes two cases in which, after prolonged treatment and freedom from symptoms, patients were allowed to marry, no infection of the wives took place, and each had two healthy children. Nevertheless each developed eight years after infection further syphilitic mischief, in one case affecting the testicle, in the other the periosteum. He concludes that the most prolonged treatment (three years FOURNIER, five years NEISSER) cannot absolutely protect against relapses. As such lengthy treatment is very depressing both physically and morally, he considers two years enough, but does not recommend marriage till the end of the third or fourth years.—*Brit. Med. Jour.*

Tricycle for Graduated Exercise.

THE fall in their bank accounts has made many of the American doctors complain bitterly against the great popularity of the bicycle as a therapeutic measure (*Med. Age*); but MARTIN SINGFRIED (*Dent. Med. Week.*) is high in praise of cyclotherapy in cases of weak heart and joint stiffness. He seats his patients (propped up if necessary with a back support) on a specially constructed tricycle whose treadles are adjustable to revolve in shorter or longer circuits. For active exercise the patient propels himself along but for passive exercise the tricycle is pushed or pulled along so that the patient's lower extremities are involuntarily moved by the revolutions of the treadles on which his feet rest.

Therapeutic Brevities.

Uhrystoxin, the newly isolated principle of ergot, fully represents that drug and remains unaltered for years.

Parachlorophenol mixed with equal parts of lanolin, petrolatum and wheat starch is a valuable application for lupus.

Powdered nutmeg sprinkled on linseed meal poultices is very useful in treating boils.

A case of deafness of seven years' standing was recently relieved by removal of a plug of cerumen by syringing the ear with hot water.

Free emesis by ipecac saved the life of an eleven months infant, who was working in strong convulsions due to accidental poisoning by a goodly quantity of pyrethrum flower insect powder.

Eka Iodoform, which is a mixture of paraform and iodoform, is extolled by GOTTSTEIN and THOMALLA as being superior to Iodoformin, the antiseptic treatment of wounds.—*Pharm. Zeit.*

UNNA finds that if the teeth are brushed with potassium chlorate for six weeks, which renders interstitial medication disappreciable like sugar while the mouth is rendered aseptic and the gums strengthened.—*Brit. Jour. Dent.*

According to SCHMIDTKE and SCHMIDT Dünroth, the activity of arsenical desquariates is due solely to the oxide and sulphide of arsenium they contain.—*Chem. Zeit.*

ALLAN and KENNEDY think that the activity of rhubarb purgatives does not depend on cathartic and volatile acid, but FARRAR holds that the acid is capable of volatilizing acid.—*Rep. de Pharm.*

Correspondence.

REPLYING to the *Indian Medical Association*, the Chamber of Commerce have addressed the Government, advising the appointment of a bacteriologist to examine the cases of plague in Calcutta and pending his appointment that a Committee, of medical aspects, consisting of both official and non-official medical men, be formed to determine whether the disease exists in the city. The Government replied three days later on 16th instant stating that plague cases had been pronounced to be such by the leading medical men, official and non-official, in Calcutta, and their opinion has been confirmed by the independent scientific testimony of M. HAFKINE.

Now, since it will be easily understood that these Societies knew that alleged plague cases had been pronounced to be such by leading medical men, and also that M. HAFKINE had reported that the plague bacillus was present in such cases, it is plain that the reply of the Government, in merely reiterating these facts, does not expel their doubts either as to the reference of the medical men or the scientific testimony of M. HAFKINE. I think myself it would be a great mistake to appoint a bacteriologist and pit him against another. The old case of SIMPSON and CUNNINGHAM would again be repeated. It will be remembered that CUNNINGHAM stated that air bacilli had been cultivated by SIMPSON, and that they were non-pathogenic. But SIMPSON could have retorted that micro-organisms, when growing in artificial media, produced excretory products, the presence of which destroyed the virulence, and possibly CUNNINGHAM was under a deception through them. Be that as it may, the fact remains that able men held with SIMPSON that they were true cases of plague, and Dr. WEIR, the Health Officer of Bombay, who could outweigh a hundred times the experience of CUNNINGHAM in plague cases, said, only the other day, that SIMPSON was right.

The best way for Government would be to give instructions that seeing that the germ theory of disease is believed by many of the medical faculty, due place be given to the teaching of bacteriology in connection with physiology and histology, so that its doctrine may become familiar to students. To make a specialist chair for bacteriology would be a great error, for it has only got its own place, among others, in medical sciences, while the other day this error was signalled by the absurd exhibition of leading medical men in Calcutta declaring, as provisionally true, the proposition that certain cases were plague cases depending upon the report of a chemist in Bombay.

The diagnosis of plague cases is evidently difficult, and the source of much difference of opinion amongst medical men, and the lesson to the Government is that only at least experts should be permitted to be the judges, and that any malicious falsehood used for report should be carefully examined before any vote or sentence be taken to the door of the reported suspected case of plague. The position of Mr. BAKER is inevitable. He says in

GAS WORK HOUSE, BRALDAN, 30th Dec 1932

HOSPITAL ASSISTANTS' GRIEVANCES: A SURE AND QUICK REMEDY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—A world of meaning not easy to put into correct English lies in the Hindustani couplet which tersely but truly says :—

Wagt + Karurat choo sunimad gurata.
Dost bagirad nr.: shamshir tetr.

Which TAVEN (I do not know his real name, though his sentiments are quite in keeping with what we feel but dare not give expression to) has freely interpreted as—

He neither pities nor grace
Who nose lops off to spite his face.
To run amok in insane ire
Is from the grid into the fire
Godfatherless no hope to rise
Where int'rest soars while merit dies.
For want of faithful friend who'll share
Our lot and our afflictions bear.
Or back us in our time of need,
Ah ! friends like that are scarce indeed
How wrong it be 'Red Tape' is right
It knows in unity lies might.
So says "you subs must not combine.
Memorials or Round Robins aign
Subordinates should not feel pain
And crushed with work must not complain
Whatever is, is for your good "
Perhaps ! If bear we only could.

If brought to bay by out off fight
 A worm will turn, a coward fight
 And infant heard try to bite,
 But we are men who've suffer'd long.
 We pray'd the pow'r to right the wrong
 Redress refused, can we believe
 Seek ye shall find ; ask to receive.
 Is meant for us ? We sought but found
 Not rosy beds more thorny ground.
 Response to ' pray'n for rest ' we made
 Came greater burdens on us laid.

When we accepted service, the Government laid down a set of beneficial rules remarkable for their non-observance and promised to replace our mothers. If a baby is hungry or in pain, it cries because it cannot speak, and its mother immediately turns it or tries her best to find out what ails it. Is our Government motherly in conduct? Not by any means. She hands her responsibility over to a number of officials, who either do it capotally, or make their legislative work on paper difficult, or in the worst way, waste it in themselves in pay the slightest attention to her troubles.

he is forced to accept such, and he is not allowed to be tolerated, and while the best of the noblest, and condescending philanthropies of every nation, while he is associated with, but does not share in, is considered a living protest against the thousands of distresses being thrust upon the millions of unfortunates, he is worth—a typical example of the gold ring in a pig's nose. In fact for him it is the old story of the unfortunate man, his son, and his son, who strive how he would, could do nothing right. How late he realises he has mistaken this with the wind for the friendly light that would lead to shelter and comfort at last, after all his weary plodding.

Each one with me now to consider the effect on the service to which the individual may belong. Limiting, as it does, its aspirations, crushing out all encouragement towards improvement, stifling all emulation, and thus supplanting a vital spirit de corps by a lethargic sense of doomed degradation—of epitaphs under a ban—a ban the more galling that it crushes down his posterity—a veritable brand of Cain—without one cheering ray of hope in the distant vista, the future stretches before him and his children—aye! and his children's children: the weary, monotonous and senseless round of toil and moil; to rise unrefreshed from the feverish slumbers of a mental pandemonium, engendered by these reflections, only to be confronted with the prospect of being no nearer the end of these ever circling, ever recurring exertions on a treadmill, until the merciful hand of Time—as in the case of the born slave—blunts the perceptions and sensibilities, the cravings and yearnings after a better state, a greater degree of bodily comfort—not so much for himself as for his children—and a freedom from the thralldom that will surely eventuate is a return to little better than the level of the brute creation or savagery—what effect, I ask, can all this have on the community and through it on the individual, but a progressive deterioration, mental, moral and physical, the first symptoms of which unfortunately are but too apparent already in the listless apathy that characterises his drudgery career? Better for, that discarding all false notions, you take to the spade and plough—the drudgery at all events need not be perpetual—and side by side with the Aryan you affect to despise, learn at least to acquire independence, a love of freedom—the best attribute of manhood,—and to appropriate the advantages that hope and emulation confer on your exertions, in earning honestly at the sweat of your brow or by your innate abilities, that degree of comfort and happiness you may attain to—your motto even, as your clerk, Bachelor! I put it to you now, are you content to thus put yourselves in a false position, to allow yourself to be hoodwinked, and by the acceptance of this role, to acquiesce in its being taken for the admitted gauge of your hopes and aspirations: to move about with a consciousness that your presence is always provocative of a suppressed titter—none the less faint because it is not a frank and honest laugh? If so, there is nothing more to be said on the subject, as it concerns you personally, for though you may allow that your children might protest against their fathers being thus fettered, you would probably hold that they must work out their own salvation when their opportunities. To those, however, who think otherwise my appeal is directed, that

never leaving the shelter of their fathers' feet, they do not the sons of the British Empire, but his sons in anything but a shadow, but committing the cause to their hands, to save themselves from disaster and a painful end, driven and writhing the corner stones of the house they belong to, by asking that members of the Commission be no longer the monstrous chimera of a, but a good translation to that coveted position, entailing immediate removal from all subordinate duties, and affording the opportunity of commencing a fresh career, with renewed vigour and a lighter heart, even so late in life: so that they could look back with pride, and feel no sense of humiliation in acknowledging connection with a service that offered so high a range of possibilities to ability and merit with such far-reaching results. Think of how in after life your children to whom your sacrifices have ensured a respectable and comfortable start in this world, will feel no shame in acknowledging you publicly; and bless you for having removed a stigma that is an effectual bar to their further advancement. In asking for this reform you are advancing no new or startling demand; but merely the extension of an existing system, the results of which must be beneficial to all concerned, and tend to more harmonious working in the contentment and satisfaction of a useful and not unimportant body of Her Most Gracious and Imperial Majesty's humble servants. A precedent even, in the application of the principle to Military Medical Subordinates, is not wanting, for we have but to point to the Army Hospital Corps in Europe for one, which was instituted by no less a personality than H. R. H. the Duke of Cambridge himself.

Yours &c., No DRUMAGENE.

HIGHLY PLACED ANGLO-INDIANS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In sending you a few additional names of members of our community who have done well for themselves, I embrace the opportunity of enclosing you an extract which I made from a letter of a correspondent to the *Civil and Military Gazette* the other day on the "Anglo-Indian Question," as I am sure your readers will be glad to read it, and I also think it might very properly find a place in your valuable journal under the heading of "HIGHLY PLACED ANGLO-INDIANS":—

1. Thomas Taylor, Civil Sub-Judge, Retnagbari.
2. Henry Ingle, Deputy Collector and Magistrate, Karwar.
3. James David Wilson, Assistant Engineer, P. W. D. Karachi (Sind).
4. William Patton, Senior Deputy Collector, Sind Commission, Assistant Deputy Commissioner of Paper Currency, etc.
5. Cornelius Dewey, District Traffic Superintendent, G. I. P. Railway, Bombay.
6. John Henderson, Chief Superintendent, Rail Brothers' Agency, Karachi.

Here is the cutting from the *Civil and Military Gazette*:—

"Men like the Kallans, Behrambhai, Trilling, Hellingbury, Fisk, Chisholm, Tyler, Sweetingham, Kennedy, Macpherson, and a host of others I could mention, are all descendants of Englishmen, who could justly be

Professor of Chemistry in the Medical College, and Chemical Examiner to Government.

Surgeon-Captain T. Foulkes, I. M. S.

Surgeon-Captain A. E. Berry, I. M. S.

Surgeon-Lieutenant C. Webster, I. M. S.

Surgeon-Lieutenant C. H. S. Lincoln, I.M.S.

The last three officers received their medical education in Madras, two of them taking the L. M. & S. degree of the local University.

Dr. Oliver, M.D., Medical Officer to the South Indian Railway.

Dr. G. N. Coombes, Medical Officer to Cochin Government.

Dr. H. H. Marshall, Health Officer, Bangalore.

Dr. Trip, once a Military Assistant Surgeon, and now Assistant Director-General of H. H. the Nizam's Medical Service, and Lecturer in the Nizam's Medical School.

Surgeon-Captain and S. A. S. R. Hollingsworth, I.S.M.D. Professor of Botany in the Medical College, and Examiner of the same to the Madras University.

This officer is the leading botanist of Southern India, and on his retirement from the service shortly, it will be rather hard to find one to fill his place either from the I. M. S. or elsewhere.

Assistant-Surgeon S. E. Falconer, I.S.M.D., L.R.C.P. &c., Professor of Midwifery to lady students, Medical College, and Resident Surgeon, Government Maternity Hospital, Madras. As a Gynaecologist and Obstetric Physician, there is none to equal this M. W. O. in the Presidency. He commands a very extensive practice.

There are also some officers in the A. M. S., but I think it best not to publish their names.

Yours &c., L. M. & S. (Madras)

—:O:—

THE SUN LIFE INSURANCE COMPANY OF CANADA.

TO THE "EDITOR, INDIAN MEDICAL RECORD."

SIR,—The following letter demands publication in the Record:—

INDIAN MEDICAL RECORD OFFICE

Calcutta, 50 Park Street, 16th May 1898

D. F. WADE, Esq.,

57, Esplanade Road, Bombay.

DEAR SIR,

Your letter of 15th May to hand yesterday (Sunday) 15th May. I beg to reply thereto to-day, 16th May, as follows:—

1. With regard to your inference that the "Correspondence" article in the *Indian Medical Record* of the 16th April, having reference to certain enquiries made by a medical officer over his own genuine signature, is malicious and libellous in effect towards the Sun Life Assurance Company of Canada, on whose behalf you address me, I absolutely deny any such intention.

2. The letter was published in good faith and for the public good.

3. If your clients consider that anything in connection with the article or letter in question may be construed in such way as to have any evil or harmful effect in the Sun Life Assurance Company of Canada I hereby express my regret

that the article was published, and I withdraw any statement in such article that might be so construed.

4. I hereby demand, not only in the interests of the medical officer who publicly placed his interrogations concerning the Sun Life Assurance Company of Canada in the columns of my journal, but for the public good, a complete answer to such interrogations from your clients, with a view to publishing the same in the next issue of the *Indian Medical Record*, together with this letter.

Yours faithfully,

JAMES B. WALLACE, M.D., F.R.C.S.

Editor and Proprietor, "Indian Medical Record"

—:O:—

TO CEYLON AND SINGAPORE READERS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—May I ask, through the medium of your widely read columns, if some of your Ceylon and Singapore readers will have the kindness to furnish me with some information regarding the incidence of malarial fevers in those places, which I stand very badly in need of.

I want some exact information as to the months in which malarial fevers are most prevalent in Singapore and in the south and north of Ceylon.

If possible, the exact number of admissions for every month in the year, or for a series of years, for intermittent fever, out of a population of given strength, either European (soldiers) or native, or preferably both.

Yours &c., R. B. H. MOORE, M.D.

Surgeon-Major, A.M.S.

DARJEELING.

(We commend Dr. Moore's request to our readers in Ceylon and Singapore and we trust the information sought will soon be forthcoming.—Ed., I.M.R.)

Book Reviews & Medical Trade Notices.

THE MEDICAL ANNUAL AND PRACTITIONERS' INDEX. A WORK OF REFERENCE FOR MEDICAL PRACTITIONERS.

(Publishers: JOHN WRIGHT AND Co., Bristol, SIMPKIN, MARSHALL, HAMILTON, KENT & Co., Ltd., London; &c., &c., Pages xcii—847. Sixteenth year, 1896.)

WHILE deserving to be warmly congratulated over their sixteenth annual issue, the publishers may rely upon receiving the continued support, approval, and encouragement of the medical world. The volume before us abounds in original articles containing information which it would scarcely be possible to obtain from other sources, and is illustrated by elegant tinted plates. In addition to such useful sections as the lists of the books of the year, medical periodicals, new inventions, &c., a distinctly novel feature is the report of the legal decisions which affect the medical profession directly or have reference to the question of the public health. Altogether, the *Medical Annual* for 1896 should go a long way in maintaining the very high position already reached by its predecessors.

REPRINTS OF LATIN FOR STUDENTS OF MEDICINE AND PHARMACY.

By GEORGE D. COVINGTON, M.D., M.D.

Teacher of Latin and Greek in the St. Joseph (Ho.) High School; Formerly Professor of Latin and Greek in the University of Omaha.

AND HIRSH H. BROWN, A.M.

Instructor in Latin and Greek in the Boys' High School of New York City.

5½ x 7½ inches. Pages xii-242. Flexible cloth, \$1 25 net. (Publishers: The F. A. Davis Co., 1914-16 Cherry St., Philadelphia; 117 W. Forty-Second St., New York City; 9 Lakeside Building, 218-220 S. Clark St., Chicago, Ill.)

There are certain principles of Latin etymology and construction which become essential to an intelligent use of medical terminology, and these principles are presented within the briefest possible compass in the work before us. The value of the publication is no doubt enhanced by the fact of its joint authors being Professors of the Latin language, while one of them is a duly qualified Doctor of Medicine.

THE POCKET FORMULARY FOR THE TREATMENT OF DISEASE IN CHILDREN.

By LUDWIG FREYBERGER, M.D., M.R.C.S.E., & Co.
(Rebman Publishing Co., Ltd., London.)

THIS work contains in a concise and handy form all the information which may be required by the busy practitioner and the senior medical student on the treatment of children's diseases by drugs. Of the latter an alphabetical arrangement is made, while their properties, uses, doses, incompatibles, therapeutics, connection of taste, formulae, &c., are set forth separately and clearly, immediately following the name of each drug. This arrangement, a really excellent one, has been made with the object of facilitating rapid reference.

The little work is elegantly bound in padded black morocco, with red edges, and should be in the pocket of every practising physician.

RHEUMATISM AND ITS TREATMENT BY THE USE OF THE PERCUSSO PUNCTATOR.

By J. BRENDLEY JAMES, M.R.C.S.E.
(Rebman Publishing Co., Ltd., London.)

THIS small treatise is a second edition of a very valuable paper read by the author at the Annual Meeting of the British Medical Association, held at Cardiff some years ago.

He is the inventor of an instrument termed the *Perusso-punctator*, whose efficacy, having since its invention been "unchallenged," renders the author more satisfied with it than ever. Chapters are added on the treatment of sciatica and lumbago by the injection of sulphuric ether, and on the prevalent nervous disorders of the day.

INJURIES AND DISEASES OF THE EAR: BEING REPRINTS OF PAPERS ON OTOTOLOGY.

By MACLEOD YEANLEY, F.R.C.S., &c. &c.,
(Rebman Publishing Co., Ltd., London.)

THIS little work is a collection of valuable papers which have appeared before, principally in *The Medical Times*,

and *Hospital Gazette*, &c., and are now re-printed and partly re-written. They deal respectively with artificial membrane Tympani. Foreign bodies in the ear and their treatment; What not to do in the diseases of the ear; The use of the Pneumatic Aural Speculum; The cure of the Ear in Children; and Aural Reflexes. These are considerations of the highest importance in connection with the important feature of the human ear, and are clearly and concisely dealt with in this little book under review.

THE LONDON AND LANCASHIRE LIFE ASSURANCE CO.

FROM the thirty-fifth annual report and subsequent valuation of the above Company, up to the end of last year, we glean that the new assurances amounted to 3,446 for £1,166,775, and deducting declined and not completed £254,286; the policies issued were 2,870 for £912,489, giving a new premium income for £255,600, there being an increase after some deduction of 13,098 over the previous year. The claims by death amounted to £36,080, and matured endowments to £15,668, making a total sum of £111,699. The total increase was £379,314, including £40,500. After all payments the invested funds have been increased by £80,790 and now stand at £1,233,842. From all these figures it is apparent that this old and well-established firm has a brilliant future before it, the year's operations being all that can be desired, and the funded capital of the company able to meet any and all requirements made upon it.

WINE OF COD LIVER OIL.

WHEN consumption, scrofula and other wasting diseases assail the body, or when unhealthy conditions imperil nutrition, cod liver oil, peptonates and iron separately or combined are always recommended by the profession, but as patients do not always take kindly to these medicines in their ordinary forms, Messrs. FREDERICK STEARNS & Co., whose preparations have honestly earned a world-wide fame, perfected a pleasant tasting *wine of cod liver oil* (each ounce containing 4 grains of peptonate of iron and the alkaloids and other active principles of 2 drachms of pure cod liver oil) whose virtues they put to a long series of crucial clinical tests by the hospitals and leading physicians of Detroit, before they offered the wine to the public and medical profession at large.

HÆMOFERRUM.

IN the treatment of anæmia, which depends on a deficiency of hæmoglobin, iron heads the list of remedial agents. The question arises which is preferable an organic or an inorganic preparation of iron. Common sense decides for the former, which is less irritating to the alimentary canal and is better assimilated by the system. And what better than hæmoferum, which is obtained from the red-blood corpuscles of healthy eam and in which the iron exists in the form of a natural proteid, just as it exists in the blood itself? Nothing. Only see that you get what you want. Any respectable chemist will supply you with genuine hæmoferum in either the liquid or solid forms, prepared by Messrs. FREDERICK STEARNS & Co.

VIBRONA.

FLETCHER, FLETCHER AND Co., 469, HOLLOWAY-ROAD, N.

VIBRONA is a standard preparation and consists of a delicate, pleasant-tasting red wine containing an exact and constant quantity of the principles of cinchona bark. Moreover, these principles are presented in such a form as to obviate the distressing results frequently following the administration of ordinary cinchona extracts well known as cinchonism. This result is secured by combining the cinchona principles with bromine. Our analysis of the sample submitted to us confirms the claims made in its favor and in regard to its composition. The analysis was as follows: alcohol, by weight 18.48 per cent., by volume 23.64 per cent., equal to proof spirit 39.68 per cent., and mineral matter, 0.28 per cent. The total alkaloidal constituents amount to nearly a quarter of a grain in two fluid ounces. The wine is stated to be examined at intervals with the view of maintaining its standard of strength. It is slightly but agreeably bitter to the taste. The wine was perfectly sound and free from sediment. As the above results indicate the wine as clearly a tonic preparation of a superior character. An interesting description of Vibrona, as well as other preparations, including a champagne, appears in a very neat and artistic brochure which has been drawn up and printed "for private circulation" by the above firm.—*Lancet*.

DIASTASE-STEARN'S.

WHICH is put up in both the liquid and the dry form, is a carefully prepared diastase derived from the pancreatic juice of the pig. It is not a proprietary medicine, and the above name was given to it by Messrs. FREDERICK STEARN'S and Co., to distinguish it from other brands of diastase on the market. A number of physicians, some exceedingly high in official life as clinicians, whose opinion is eagerly sought, bear testimony to the excellent therapeutic value of this preparation in helping the proper assimilation and quick digestion of food.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

The services of Brig.-Surgn.-Lieut.-Col. W. McConaghy, M.D., J.M.S. (Bombay), are replaced temply. at the disposal of the Milly. Dept.

WALL.—On 29th April, after a long and painful illness, Alfred John Wall, M.D. Lond., F.R.C.S., I. M. S., (retired list), aged 50 years.

IRVING.—On 2nd May 1898, at his residence, Clifton, James Irving, M.D., late Surgeon-General of Bengal, for many years Civil Surgeon of Allahabad, aged 76 years.

PARTRIDGE.—On 7th May, at his residence, Thicket Lodge, Anorley, Depy Surgn.-Genl. Samuel Bowen Partridge, C.I.E., Q.M.S., Bengal Medical Service (retired), aged 69 years.

NOTICES TO CORRESPONDENTS.

M. M. (Gaderwara).—A European surgeon, for removing a necrosed metatarsal bone under chloroform in the patient's own house, would probably charge four gold mohurs as his own fee and one gold mohur for the chloroformist. We think a similar operation performed by a Hospital Assistant, under similar circumstances, should entitle him to a fee of at least one gold mohur or even twenty-five rupees, and five or eight rupees for his assistant who gives chloroform.

N. E. J. (Kote Diji).—If a member of the Association loses his original certificate, he should apply to the Secretary for a duplicate copy. This will issue on the order of the Council, and after the payment of a fee of Rs. 5 for the duplicate certificate. The member must have paid up all his dues.

Members of the Indian Medical Association.—The Secretary desires us to notify that many members have not remitted to the Treasurer their yearly subscriptions. All defaulters are kindly requested to fulfil this duty without delay.

Defaulting Subscribers of the Record.—The manager has much pleasure in stating that all but a very few of the defaulting subscribers to the Record have loyally paid up their dues. He is loath to publish the names of the remaining defaulters, and trusts they will spare him this unpleasant task.

F. D. P. (Secunderabad).—Some but qualified medical men and women are admitted into the Indian Medical Association.

THE SANITARY CARE OF THE SOLDIER
BY HIS OFFICER.*

By HUNTER, COLONEL G. J. H. EVATT, M.D., A. M. S.
(Continued from page 130, Vol. XIV.).

31. In those bad old times it was an often quoted saying of old school Generals that the opinion of the military doctor was valuable when it was asked for, that is to say, no sanitary initiative existed for the doctors. Since 1887, however, this power of sanitary suggestion has existed, and with thoroughly sound results. In studying the above death-rates of the army, we should note that consumption caused 67 per cent. of all the deaths in the Household Cavalry during the pre-Crimean period, 50 per cent. of the deaths in the cavalry of the line, and 57 per cent. of the deaths in the infantry were from consumption, a probably preventable disease caused or greatly developed by overcrowding in the barracks. At the present time the death-rate of the Guards has fallen from 20 per 1,000 per annum, that bad standard of old years, until, in 1890, it has fallen to 9.88 per 1,000, and you will find in the A. M. D. Blue Book that in the year 1891 the report shows that the death-rate of the army had fallen to 9.13 per 1,000. What is the cause of that? It is, I think, largely caused by the better space and the better sanitary conditions and environments that the soldier is living in, and these results have been largely owing to the sanitary advice of the medical service acting in preventive capacity as the preventers and not merely the curers of disease.

32. It is in the discharge of this duty that the greatest moral courage and independence of character is needed. There is nothing more easy and charming than to go to a great hospital and to work there; no one interferes with you and you may make yourself a great name. I may serve in a far-away garrison in India and may make a great name by treating the 50 or 60 cases of typhoid that occur in the year, and may be much thought of and honored. There is a better way to make a great name. I say that if my child is ill and there is a doctor close by who can cure him of diphtheria, he is a good man, but the doctor who prevents the attack occurring is a better man. That military doctor who, knowing the soldier's sanitary wants, his water supply, his clothing, his food and his surrounding, and who seeks the reasons why a man is getting sick with typhoid, is a more useful man to the nation and the army, and a better man than the other, however good he may be. You want in the army, as a Medical Officer, the man who will give you in the battle 10 more men to your battery or 100 more men to your regiment. Is that the case or is it not? It is most certainly. I say that the sanitary side of life is of great importance. You may read in the military papers letters which say that the military doctors should be what they call a doctor; they think and talk as if in England there were not more than 1,000 doctors who do no curative doctoring whatever in the way of prescribing for the sick. But the 1,000 doctors in the public health service of England are most useful men, and have far greater authority as

regards the sanitation of the army, and the sanitary condition of the people than we have in the army. These physicians are just as much doctors as the others, but they are dealing with a different side of the question of life and its ailments, etc., with the question of prevention of disease; and for you in the army it is of great importance that you should not get in the military service weak-kneed and craven men afraid to speak on sanitary matters, but men of rank and standing who would be able and willing to speak out and point out the path to sanitary improvements.

33. The army death-rate has thus fallen largely by going into sanitary matters, and you have benefited by it, by having men in your ranks of the army healthier and readier to go to war. Short service, no doubt, has also to be considered as a factor in this matter. While the death-rate has fallen and invaliding has fallen, it must be remembered that the soldier to-day stops with us but a short time, and the health returns may, perhaps, be vitiated somewhat on that account. I came home last year from India in a crowded Indian troopship, and I saw that point very marked. Many of the men there were not invalids officially (nor did they appear in any invaliding returns), but they were no more fit to go into the English labor market and compete with healthy English laborers than any of us coming home seedy with ague would have been. Their unfitness was entirely owing to the Indian climate, although it figured in no return. They had not, however, re-engaged. Many said to me, "It is too much bother to re-engage; I am constantly getting ague and feeling seedy, and I am going to the reserve." In the old days when I joined we kept those men and they could not get away; in fact there was no chance of getting away except invaliding, whereas now men simply do not re-engage.

34. This question of bad air and overcrowding of barracks is of the greatest importance for this reason: Impure air goes directly into the lungs, but bad water may be killed in the stomach. I may drink bad water and the juices in my stomach may kill the bad water, and I may survive. It is well known that 2,000 persons in a large church or building will in two hours give off 17 gallons of water and as much carbon as would come from one cwt. of coal. That is not a very pleasant atmosphere if it is not constantly changed. Do not forget also that 30 grains of organic matter are given off per man per day from his body in the shape of worn-out skin and debris of the body. The smell of the men in barrack-rooms may be very unpleasant and most trying, altogether caused by the closeness of the men and the want of fresh air. And that affects the men's health and discipline. You must remember that the barrack-room is not only a dormitory; the men are eating and drinking and sleeping in it, brushing their dirty boots in it, brushing their dirty clothes in it; pipeclaying their belts in it, and smoking in it, too, and the air can become very vitiated from all that. In dealing with the question of overcrowding, then, we have got to bear this in mind, that we are dealing with a fixed law which we should recognise very fully as to the danger of interfering with the cubic space allowed to the soldier, and I trust that whenever letters come to you on this matter that you will receive with great consideration any suggestions with regard to any question of overcrowding.

* A lecture delivered at the Royal Artillery Institution, Woolwich, and read to the Society of the Service.

35. *Urinals*.—It is very needful we should speak here about the question of urinals. There is still in all the barracks in England, or in most of them, this horrible urine tub—that is to say, you have a horrible looking thing, a wooden tub; of all things most highly absorbent; which is supposed to be tarred every quarter, and into this the men urinate. I must tell you that no light is allowed at night by the regulations for this tub. The soldier comes out of the barrack-room on to the lobby; there is no light, and the consequence is (and we may see it in most barracks) that the ground round the urine tub is constantly saturated with urine. And a case has occurred, I think, even in this garrison, where the urine has gone not only on to the floor, but through the floor, and has come out on the roof of the room below. A case occurred before my eyes where a soldier on the inner side of the room was sleeping with the head of his bed against the wall where the urine tub was and the urine soaked through, and he complained, and I think justly, of that urine coming out towards where his bed was. Those questions are very important. We want, in the first place, light at night over the urinals, and we want regular urinals built as you see them at railway stations, and attached to the buildings with water flushing them and light over them, where the soldier can urinate without soiling the floor and tainting the air of the barrack passages. Why should railway stations and other places beat us in civilisation? I think we can get these urinals if we jointly push the matter, and we mean to do it; we will push away at this urine tub and get something better for the soldier. Even an iron bucket would be better than an absorbent wooden tub.

36. *Baths and Lavatories*.—My next point is about bath-rooms and lavatories. I could not exaggerate to you the defective condition as regards cleanliness of the person of our soldiers. No one sees as we in the medical service do the absolute filth of the soldier's person. A man comes up before me well dressed and well turned out, but he is a "whited sepulchre"; the condition of his person and the odour that comes from him are very unpleasant. What is the reason? The reason is that the regulations only allow one per cent. of baths for the troops; that is to say, that for every 100 soldiers only one bath is allowed; and they allow 12 basins per 100 soldiers and four foot-baths. But you must remember that the soldier is not allowed any warm water to wash with. I cannot tell you what an important matter this is. This odour, this *debris de corps* in the very worst sense, which comes from the body of the soldier is most offensive. If anyone will come over to the Auxiliary Hospital in the morning you will have a smell like the odour of a troopship in the Red Sea. Now, all that arises from preventable causes. We want warm water laid on most awfully. I maintain that from the 15th of October to the 15th of April all bathing ceases in some garrisons, and the body of the soldier is not washed at all. That comes before us doctors in the most striking way. I have to examine a man's chest and the odour is most trying. Remember the cubic space is based on the clean man; but you have this man going to bed in the barrack-room with his body not washed, so that the air becomes offensive and tainted, and this affects the health, the fitness, and, in the end, the discipline of the soldier.

37. As you know in this garrison here during the past few months a great improvement has been made; that is to say, that by the efforts of Colonel SPRAGGS warm water arrangements have been placed in five groups of barracks, and I had an opportunity the other day of totalling up the number of baths taken. I beg of you not to say that soldiers will not do certain things, for I find that between the end of November and the 13th of January in this garrison 1,300 warm baths were taken in one of the five groups of barracks alone in the baths quite lately put up. And those baths, mind you, are worth in the town 6d. each. What is going on round the barracks here? Every possible religious denomination is going in for baths for the soldiers; you can get a Church of England bath, or a Wesleyan bath, or a Unitarian bath, you can get all kinds of religious baths, but no State bath. But the State is bound to wash the soldier. A devoted lady, devoting all her time to the soldier, said to me the other day. "We do so much want a bath!" She suffered very much from the odour of the soldiers in going amongst them. Now, we must do away with all this bathless condition. My own view is that we cannot provide little trumpery bath-rooms in very small groups of barrack-rooms, but just as the Municipality are building public baths there should be in every large barracks a separate bathing-house in which men could have plunge baths and wash and bathe themselves thoroughly.

38. I would ask any gentleman going round the town here to go to the public bath buildings opposite the Town Hall, and I maintain (I do not care what his views are about baths) that he will be surprised at the municipal baths of Woolwich—they are splendid. The Municipality of Woolwich is laying out £40,000 to wash the Woolwich people, and you would be surprised—I maintain whatever your dreams are they will be exceeded. There are two magnificent plunge baths into which you might put, I will not say an ironclad, but a very large vessel, and there are exceedingly good first and second class baths which provide everything that is wanted. If a soldier is in the army, where he cannot express an opinion and has no vote, it is necessary for his officers to put forward this matter thoroughly for him, and to say that it is affecting the recruiting of the army; that better men will not come to us because of these things. If a man outside in civil life can go to the Municipal baths, he will look upon the army when he comes to it as below a healthy standard. You must advance as the civil population are advancing. Look at Plumstead! You see house after house by hundreds built for workmen who a generation ago were living in single rooms, as 80 families of our own live in Woolwich. We have to-day 80 families living in 80 rooms, each family having but a single room. Then, I say, the baths have been thoroughly appreciated, and the result of our inspections on the Saturday is very marked. In one unit particularly I was charmed with the cleanliness of the men. I think I told an officer here about it, that their feet were so clean that they could have been used as ornaments for a lady's table. You come and say to me, "Oh, but they will not care for them; they will not use them." But they will do much if only we teach them to do it.

39. *Married Quarters*.—I should say a word here on married quarters. I have said already that we have 30

families have living in 80 rooms, each family having but a single room. The new regulations from the Quartermaster-General's Department, about married quarters, seem very reasonable and very just. Quite recently I had the pleasure of going round the newly-built married quarters, and there is in them a great improvement in space and comfort. I think they quite satisfy the dreams of the most idealistic man. The whole system of married quarters is an evolution. Formerly the wife was not recognised at all; then she crept into the barrack-room and slept there, with a sheet or blanket put across to screen her from the soldiers. This was in the good old days, which were really the bad old days. Then she moved out of that, and then they gave up the barrack-room to four or five families; that existed in my day, in Chatham, in 1865. Then they went from that into a single room built as married quarters. Next year, when they will go into the New Brookhill Quarters, I think the demands of the most exacting sanitarian will have been met for the time being.

40. *Latrines*.—We have spoken about the percentage of baths, one bath being allowed per 100, and four foot-baths per 100; but the soldier has also the right to go to the latrine. But it may be full at times, and I have seen great trouble in that matter. What accommodation do the regulations give to the soldier in that respect? They allow five latrine seats and five urinal spaces per 100 men! The question came before me the other day, and how did I find it out? I searched book after book, and suddenly by good luck I came across a most valuable book. I will tell you the name of it: it is called "The Synopsis of Barracks and Hospitals," and it is kept up in the Commanding Royal Engineer's Office. I maintain that there is no book that I know of that ought to be more in the hands of Commanding Officers. I have not got one, the Principal Medical Officer has not got one; not a single officer has got one, and I do not know who has except this one copy in the Commanding Royal Engineer's Office. This gives us all details about the baths and latrines; it is not in any of the regulations. We have volumes of military books, but this very vital book is not there at all. I would say that the Government or the Military authorities would do well by publishing this book; it is not anything confidential, it is the number of baths and basins, of latrine seats, and the amount of cubic space, and many useful things about hospitals. I was thinking about blinds for my hospital and how I could approach the Commanding Royal Engineer, when I found in this book that blinds for hospitals are allowed, and at once I applied for them. But we do not want to be fighting these kind of questions all over the Empire; we ought to have this book given us. I applied officially, through my superiors, to get a copy, and the reply was that this book is only supplied to the Commanding Royal Engineer. *It is the family secret, as it were, of the Royal Engineer Corps.* Why, I do not know, as it is needed by the whole army. I hope it will be made an official book.

41. The question, then, of latrine accommodation is important in this way, that last year in India (and when I think of the charming young officers who have died in India it is most sad) we had 1,200 cases of typhoid amongst the young soldiers in India, and caused by death 300 of the Indian garrison by typhoid alone. The ques-

tion, therefore, of the removal of latrine matter is a most important question, and you must not look at these questions as beneath notice. I cannot tell you how painful it is sometimes to go round on a barrack inspection. You come round by the Principal Medical Officer's direction. The Medical Officer goes to inspect the barracks, and who goes round with him? I have myself gone round with the Quartermaster, and have been met by a casual Subaltern, who looks upon the whole thing as a very great bore perhaps, and when you go to the latrine this Subaltern stands aside and the Quartermaster and the Doctor walk in. Believe me, gentlemen, that "command" includes the latrine also. If you look the matter in the face there are lots of men in the barracks standing looking on, and if they see the officers stand aside they say it is not of the least importance. Now, I maintain that it is of great importance. Here again, I say, there are two armies: there is the army of the "Queen's Regulations," which is kept tight and hard by the regulations, and there is the rational common-sense army. In the army of the "Queen's Regulations" a Captain or a Subaltern takes the Principal Medical Officer round; but there is another common-sense army, in which the Commanding Officer himself goes round with the Principal Medical Officer. Believe me, that the Commanding Officer, just like the Irish landlord, has his duties as well as his rights. You must remember that your command is supreme, and when the Commanding Officer goes round with the Principal Medical Officer, the result is enormously good. The Subaltern does not know much about these things, but the Commanding Officer is responsible to the army and to England for all these things. I maintain that it is absolutely essential; it is not a question of rank, but is of great importance to the soldiers.

42. *The Soldier's Bedding*.—I would like to say a word here on the question of the soldier's bedding. The soldier is allowed 24 lbs. of straw per quarter, and with this he makes the bed and bolster; no pillow is allowed him. I have brought with me here to-night the two sheets which are used in the army; I think it will be instructive for you to see them. One is the hospital sheet which is used by the soldier in hospital, and the other, which anyone might imagine was a piece of navy canvas, is the soldier's barrack sheet; it is a piece of canvas which has come here by mistake, and is called a barrack sheet. We are now pursuing the reasons why the barrack-room smells. The soldier does not wash; the men are lying there close together; the ventilation may be interfered with. But we now come to the bedding. The bedding is of straw and he gets two sheets. How often are they changed? They are only changed once a month, and the condition of those sheets, when they are used, becomes something very marked indeed. A soldier, mind, who does not wash, and whose body is not always clean, is lying for one month between those two pieces of canvas, and the result is very trying. I maintain that we might go to the country with a cry of a fortnightly washing for the sheets; and it would be a great comfort to the men. But you must also remember that if you give this coarse kind of sheet to the soldier he will not use it at all, and I find that only about one-fourth of the men use their sheets;

the rest of the men turn in in their flannel shirts. And in the artillery, where they have got drawers, they turn in as they come out of stables. A man goes to the stables, where he works all day and sweats hard (because your drivers work very hard indeed), he comes out with his drawers and shirt soaking in sweat and turns in and lies in this sweating condition in the blankets, and the blankets are washed only once a year and the sheets once a month. This man comes before me the next morning at the Auxiliary Hospital, I strip him, and he comes out of his flannel shirt that he has been sweating in for a week, and he puts off from his clothes a small portion of horse manure that comes out from between his waist-coat and his flannel shirt—that is to say, the man has turned in and has not changed his clothes in any way. And we want to look into those questions.

43. What, then, is done with the sheets? They are used sometimes to put over the saddlery; constantly to tie round his waist to keep him from rolling himself when he is doing up his accoutrements; they are constantly put under the pillows and beds simply for safety and not used at all. The soldier says, "Why, sir, use the sheets! I would as soon use a piece of coir matting." They also complain that the sheet is so rough that it wears out the flannel shirt which they are wearing as soldiers. A specialist in sheets told me he thought the soldiers' sheets would make excellent bath towels.

44. Then a soldier marries, and among other boons that he gets is the right to use the hospital sheets, every married soldier gets a pair of hospital sheets once a month. I asked a married woman how often they were washed, and she said, "Once a week." The police have their sheets washed once a week, and so do the paupers in the workhouses, but the soldier's sheet is only washed once a month. In Egypt they are washed once a fortnight. In India the soldier gets two sheets given to him when he arrives out, and one sheet a year afterwards, and as there he is allowed to wash them at his own expense, he washes them once a week. Then, as regards the straw pillow, or bolster rather, I find that the old soldier, the man who really likes comfort, always travels about with his own private pillow. And the married people never think of using the barrack beds; they have their own private mattresses, and they use the straw below them to make them softer.

45. But I find that in some garrisons, such as Aldershot and Portsmouth, they have issued a better bed, a coir bed, which makes a capital bed; it is used in India. The Government allows there a coir bed and it makes up a very good bed, and the men tease the beds themselves and wash the mattress case. There are 2,000 of them now lying down in the Dockyard, and I was told that there were several hundreds in use in London, and also at Aldershot and Portsmouth. They are distinctly an advantage. Therefore I think the straw bed might be replaced by the coir bed in Woolwich. Why should the soldier lie in a straw bed? We have long since chucked away the straw bed for sick men. FLORENCE NIGHTINGALE says if you want to kill a man who is seriously ill, put him on a straw bed, because it takes out much of the vitality from a man. The soldier's bedstead is 27 inches wide—his mattress is too narrow and his sheet is only 50 inches across—while the hospital sheet is 72 inches.

We want a lighter bed with waterproof material rather than the present. We want hospital pattern sheets and blankets scoured at least once every six months; the sheets must be washed every week.

46. *The Guard Bed.*—I have put down some under the head of bedding the guard-bed. A more brutal, useless and thoroughly unfit construction does not exist in the army. It is not of the least use to train a man for war. I have been in five campaigns myself, and everyone knows that no one is asked to lie on anything like the guard-bed. There is no reason whatever why the bedstead, with a mattress of hair, should not be found in the guard-room. If you speak to the soldier he will say, "Certainly, I would much sooner lie on the ground in the field than on the guard-bed in barracks." What is gained by this guard-bed? Remember that you do not harden your men. No officer ever yet hardened his men. Why, the officers beat the men in everything, and we go out to war off very good beds. If we want to be hardened let us all go on the guard-beds together. If you give the soldier a proper bed for a guard-bed he will do his guard better; it is not the sentry-work alone that knocks him up, it is the guard-bed; they are terrible contrivances, the remains of the bad old system. We want now to give the soldier a bedstead with a mattress of coir or hair, so that in the intervals of his sentry-go he shall get some chance of sleep.

47. *About the question of clothing.*—I will not now deal with the question of tunics and those things, but as regards the question of the flannel shirt. The old army wore always a calico shirt, but General HERBERT, who was Quartermaster-General 15 years ago, devised at Pimlico a grey flannel shirt which contained 47 per cent. of wool; it is not a woollen shirt altogether, but it is a great improvement upon the old one. Now we find great difficulty in getting the men to wear them. There is a laxity about it in some way; there is a want of the old parade system. I remember years ago how the soldier tucked up his sleeve and showed his clean shirt at the wrist. While you are sending men up to the hospital with bronchitis you must remember that every man whom you send up throws more work upon the men behind. If you want to know why the men get bronchitis, it is because they do not wear the flannel shirt. It is of importance that he should also have some under-vest and not go out in this poor thing he is now wearing. Then he wears this shirt night and day, and it is very dirty. There must be a reinvigoration of the cheek of the "No. 1," of whoever it is in the artillery, or the Color-Sergeant in the infantry, or the officer himself must do it. That is to say in this short service unstable army, in this raft that sinks in mid-ocean under our feet, there is only one stable element—not the non-commissioned officers, not the men, but the officers. So far as I can see, as the old system gives way and the new system comes on, it is more and more essential for the officer to be able to answer for everything about his men. I think that, as in the mounted corps you give every man drawers, you should give a pair of drawers to every soldier in the army; the men would be healthier and better, and there would not be so much coughs and colds. And I would myself like to give the men some suit to sleep in. I said to a man some time ago, "What do you sleep in; do you wear a night-shirt in

bedroom? "Oh, no, they would tear it off my back in the barrack-room if I were it." But many of these men have been accustomed to better things. You would be surprised when a man comes before you as a recruit looking grimy and dirty, and to find that, although uncared for, this man has been in his own home well-cared for. I ask him, "Did you have sheets in your mother's house?" "Yes." Then I ask, "Did you have night-shirts," and they always say they had. In the army they are sleeping in their day shirts often for more than a week, and that produces the most frightfully sickening odour in the barrack-room.

48. *Sleeping Suits.*—On the troopship and in India a sleeping suit would save much trouble. The moment I go back to India I will propose that every man should get a regulation sleeping suit. I am sure it would improve the men's health; certainly it would improve their cleanliness, and it would improve the air of the barrack-room. The whole argument about dress can be summed up in this way; believe me you cannot make any man work in one dress, whether officer or man; that is to say, for example, that a man cannot go out shooting in the Highlands in a long-tailed evening coat. We want a working dress for the army; we want something for the internal barrack life of the soldier, and we want a sleeping suit for him to wear at night in the barrack-room. I notice that in "Parkes' Hygiene" it says that the German army are to be entirely clothed in Jaeger suits under their clothes in war—that is to say, that they find that it pays. Of course, the existence of Germany depends upon her soldiers, and she finds that it pays. Bronchitis and pneumonia in the army running into phthisis causes a great loss of service to the army, and a soldier going on guard not properly dressed gets knocked up, and a thing that often attacks him is pleurisy.

49. I remember I was in a very exposed station in India where pleurisy was a very common thing, and I remember a special case of this: I was going round the hospital with a General Officer, whom everybody in this room would know if I mentioned his name, and I said to him, "This is a case of pleurisy," and he said to me, "What is a pleurisy?" I think it was a pity that he should have had to ask such a question. If a soldier were to leave his rifle out in the rain outside the guard-room and it were to get rusty in the lock you would punish him; but behind the rifle is a much more intricate and charming rifle, and that is the man who carries it. We would be better friends if you knew more about disease, and we would be more efficient if we knew something more about soldiering. I think it is essential that the officer who commands the soldier should know what disease is likely to attack him. I venture to say that there is not a good horse-master in this room who would not be ashamed if he did not know the various ailments that might attack his horse. When I go round the stables and see the charming care that is taken of the horses—why, they are gentlemen, they are well groomed, well shod, well fed, and well housed. But your men also have got to be looked after. When I look at the hoofs of the horses they are in beautiful condition. When I go to the hospital ward and turn down the clothes of the men's beds their tails at these frighten me; they stand out like

tiger's claws, they seem never to let them. They do not know how to use those things that make for sanitation, and you have got to educate them. Uncut toe-nails and filthy feet means foot-sore feet and that means inefficiency in war.

50. *The Soldier's Food.*—As regards the soldier's food question the history of its evolution is extremely instructive. Up to 1854 the Government made no contracts for bread or meat; it was done in the regiments by the Commanding Officer, who was sole master. He was sole master of the clothing, and the men got so equipped that the word "off reckoning" survives; the "off reckoning" was the cuttings off the soldier's clothes. In the same way the food also was provided by the Commanding Officer in the different regiments. It was a bad system, and the Government put an end to it in 1856. The soldier drew his pay in full, and the Commanding Officer put his ration money out of it until the Government took over the rationing and knocked 3d. to 4d. off for the cost of the ration. The soldier thus gets his $\frac{1}{2}$ lb. of meat, 1 lb. of bread, and his pay besides. The regimental rationing system broke down through regimental neglect. Of late years we have heard much about the improvement of the soldier's food, but I would say that the soldier has not gained very much from the State, despite all this outcry. We are pursued by two things in the army, the dripping-pan and the stock-pot, but the original $\frac{1}{2}$ lb. of meat is all we have as a basis to work upon.

51. I would say that the question of the inspection of rations is most important. No one, I think, can see the Army Service Corps Officer without seeing the enormous deal they have gained by the instruction classes which were formerly held at Smithfield and are now going on at Edinburgh; but I think that that information should not be limited to a corps which does not serve in India, where 70,000 English soldiers are serving under trying circumstances. You cannot conceive how bad the Indian rations are, and we all want to get a certain proportion of this instruction. There should be in every regiment a certain number of officers trained in this ration passing, and the Medical Officer should certainly get an opportunity of going through the course, because the hospital rations do not come before those highly-trained officers at all. By long service in India our eyes get trained down to the bad Indian ration, and when one comes home it is well to get up to Smithfield again to find out what the proper standard of the English ration is.

52. I would also like to say that the Medical Officer has continually before him the question as to his right on a Board. Owing to the quibble as to what his position is, many of them are afraid to say one word on the Boards. It is very trumpery. We send down four men to do what three might do, and the Medical Officer is afraid to say one word until he is asked. I have myself consulted officers and they have said that he should certainly have an initiative. Is he to remain silent and wait until the President of the Board asks him? I say he should be a member of the Board and point out freely and fully anything that goes wrong. Why should our little trumpery frictions affect the army. I say a curse on both your houses. "While we are struggling and fighting the soldier falls to the ground," but if we are to combine we

can certainly do the work better, and we cannot do the thing without hearty co-operation.

53. *The Officer's Ration and the Soldier's Ration.*—As regards the question of the soldier's ration, if you would like to compare it with the officer's ration, come with me on board an Indian troopship and see the two divisions of the ship—half the ship full of officers and half of men. I rise and come out of my cabin, and I have at half-past 6 o'clock a very grateful cup of coffee and bread and butter; the soldier at the same time has his coffee and bread in the fore-compartment. So far we are both equal. At half-past 8 o'clock I come downstairs and have a capital troopship breakfast, a very good English breakfast; the soldier has his breakfast along with my early breakfast. At 12 o'clock he has his early dinner; I come down at 12 o'clock and have a quantity of cheese, sardines, and beer. At half-past 4 o'clock he has his afternoon tea or coffee, and I have mine in the saloon. But there the comparison between the soldier and myself ends entirely. When I went out to India I found that the last meal given to the soldier was at a quarter-past 3 o'clock in the evening. I wrote to the officer in command of the ship, pointing out the long interval that he went with no food till half-past 6 o'clock next morning; there were swarms of undergrown boys going out, and those boys were getting no food all that time. He said he was awfully sorry, but he could make no change; he would refer the matter home. But when I came home the other day the same thing was going on. And, remember, I was going down at 6 o'clock to a remarkably fine dinner; dinner on a troopship is a great restorative after the fatigues of the day, but the soldier had no dinner at all, he was without it. And what would our lives be in India, or all over the world, if it was not for the messes, which have made our lives happy and pleasant? Let us remember, then, the soldier by comparison with the officer is short of one meal.

54. On the troopship you can see it in a microcosm; I am getting a good dinner and he is not. And who are these men? There are swarms of young soldiers going out to fight against typhoid who want food awfully, and there are swarms of them coming home tired and worn out by the Indian climate to a warfare which is far more bitter than any Indian campaign, the warfare in East London, leaving them far more dangerous to the public. I see them here in Woolwich. The other day I saw a man who was knocked to pieces with ague. I said, "I remember your face well." "Yes, sir, I met you out in India; I am knocked to pieces by ague," and the Indian Government, which is using these men for seven years, sends them home, and they are turned adrift at home on the same pay that a man may get by serving his whole time at Woolwich. If India uses those men I say that these men on coming home should receive a surplus reserve pay for the first year to carry them over the bad year when they are recouping from the wear and tear of Indian life. This question is of great importance. India exists by those men; the private soldier made India for us and he gets nothing at all out of it. We want to make him the same as the Indian officer who comes home on furlough. Let us give him a certain special retaining fee for the first year when he comes home, so that he

may fight his battle, a terribly bitter battle, for work in England.

55. On the question of the soldier's food we are pained by the stock-pot and the dripping pan. Now the stock-pot is not used in the great mass of garrisons, and it is not popular. The men have an idea that the stock-pot is recruited from the bones that every class of man has nibbled at the dinner table, which is not the case, of course. The removal of the bones by unhandy men knocks the meat very much about. As a result it is not much used. So far as the Government ration and the 3d. or 4d. stopped for groceries go, the soldier is still, to my mind, underfed. When you compare the feeding of different foreign armies—we do not want to compare ourselves very much with foreign armies—but there is one army that I like to compare ourselves with, which is composed of men of our own race, that is the United States American Army, which is largely composed of Irishmen and Englishmen. There the ration of the soldier is a very fine one. It is put down at 1½ lbs. of meat daily (against our 12 ounces he has got 20), and also 18 ounces of bread against our 16; he also has 1 lb. of potatoes, which our men do not get at all. We are trying to keep the soldier on a ration that he cannot do his work on. We give him his 1 lb. of bread, and his ½ lb. of meat and stop him 3d. or 4d. a day for the grocery ration, but it does not keep the man going, and the way to prove it is that in those corps that are better paid, like the Army Medical Service, the Royal Engineers, and the Army Service Corps, the men lay out much on food. Do you think it goes in drink? Not at all. A man drinks because he wants food. The measure of his shortness of food is the measure of his amount of drunkenness. And I find that in those corps the men are using their extra means largely to buy extra food. I maintain that if extra food were given it would largely diminish drunkenness. In a foreign garrison that I served in the drunkenness in certain corps was terrible; there was bad food, and, as a result, much drunkenness. Feed a man well and give him change of food and he will not drink so much; it would be a thoroughly good investment to feed the soldier well. A man wants at least his 1 lb. of meat a day. I have asked dozens and dozens of soldiers if the ½ lb. meat ration is sufficient, and I find they are all laying out extra money; those other well-paid corps are all laying out more money to keep themselves strong and fit. What for? To keep themselves strong for England's sake. Look at those young recruits who are going out to India to fight typhoid; they want to be well fed most awfully.

56. The whole subject of the fitness of the reserve soldier for hard work on leaving the army depends on whether he has been well fed in the army. If he is poorly fed, he is not fit for the terrible struggle for work in civil life. I think no work can be heavier than that of a driver of artillery, and if you want to get good work out of him you must put good food into him; in every class that is wanted. I am distinctly of opinion that he would be a seaborer and a better man if he had more food. The German war ration is very striking; it is put down in FALKNER'S book as 26 oz. of bread, 53 oz. of potatoes, 17 oz. of meat, and he also gets a ration of beer. This great fighting machine, the German soldier, fights because into

his body you put plenty of food. And in every case it is the same thing. The English navy is thoroughly well fed, and no man works like he does. And in the same way with the soldier, every penny that we give him in the way of food will diminish his sickness and his drunkenness, and it will be a capital investment. I say the measure of his drunkenness is the measure of his want of food. And also another thing is his tobacco. The soldier is perpetually smoking. I think his drinking and smoking are his attempts to satisfy his demands for food. When I have a man brought before me suffering from drink I say to him, "How much do you lay out for extra rations?" He says, "Not much." I say, "You must eat plenty of food and take less beer." Less beer and more food is quite the true principle to go upon.

57. *The Sergeant's Ration.*—And I should like to point out how one class of men has settled the question about rations; that is the sergeant class. The soldier is paying from 3½d. to 4½d. a day for his ration, but the sergeant is paying sometimes from 6d. to 7½d. But is the sergeant a harder worked man than the private? I do not know that he is physically; but he, too, wants more food, and the measure of the sergeant's money is what the soldier wants; he wants 4l. extra given him in pay or allowances to make him a better fed man. And you see it in this way: The moment a sergeant is broken, and put back in the ranks, he is pulled down at once by the want of food.

And as regards the question of men going to the different recreation rooms (which is growing up more every day) to get some more food in the evening, I would like to say that it is working up towards one thing which we have and the sergeants ought to have. What would our life be without our mess dinner? It is working up towards a good substantial evening meal for the soldier. I cannot think why the sergeants do not have an evening meal. They say it would cost too much; but it would keep them out of harm's way. When a man is eating he is in a very safe condition. The "liver" comes much more from drinking than from food. I was for several years Medical Officer of a great military school, and those years acted upon my life enormously. I shall never forget them. When I went there I found those young growing boys getting dinner, just like the soldiers, at a quarter-past 2 o'clock in the day, and they were left all the evening to their own devices, as to food supply, with very bad results. I say that for a man to live on lobsters, sardines and salmon, and that kind of indigestible food in his bed-room at night is a defective system. I say that the tea squad system was a defective system, and I know it because the cadets come before me ill, and I say that whatever I have done in my service there is nothing that I congratulate myself upon more than that I was able, by constant and reiterated reports, to get that late dinner for them; and it is a perfect success, I think, in every way. The soldier, I maintain, who is wandering round the town now looking about for amusement, and also, I think, looking perhaps for food, would be a happier and a better man if he got a good meal in the evening.

58. *Barrack Cooking.*—I would say a word also about the cooking. Throughout nearly the whole of the Woolwich garrison the preparation of the food of the men is still

done in the barrack-room. We have reports continually of the lavatories being choked by pieces of vegetables and potato skins. And the dishes are not made in the kitchen under the surveillance and instruction of the master cook; he is devoting his whole time to watching the consumption of the coal, whereas he ought to be, and is sometimes, instructor of the cook. The dishes are often made up by the men by roster, and there is not much real development in this most important art of cookery; and the result is that the sergeant cook, a trained specialist from Aldershot, is below watching the coal instead of watching the actual preparation of food. This is a matter that might well come before you. Then you ask, perhaps, is there room enough in the kitchen to do all this; it is very small. Well, a kitchen should be devised with a preparation-room outside of considerable size, airy, and clean, where the dishes could be prepared. And I think also that the day is rapidly coming when you should have a dining-room for the men, and if I could devise such an arrangement in my fancy's eye I see before me in the future a receiving-room for rations, opening next into a large room for preparing the food under the eye of the master cook, then passing by a door into the cooking-room, and then passing away into the dining-room where the men would sit down and eat their meals (not as they do now in the bed rooms), and that same dining-room if it were properly warmed and lit would keep the men together in the evening. Of course, the battery unit and the company unit are very important to preserve; and this company dining-room and battery dining-room would, I think, be a great improvement for the soldier.

59. *As to the comfort and appearance of the barrack-rooms much still remains to be done, and while referring to this point I may quote the opinion of Lord Wolseley, who allows me to publish his remarks: He says: "When I came to Ireland over three years ago, I gave orders to have not only the hospitals but all the barrack-rooms tinted a pleasant hue. I find it takes away the prison look from our barracks, which I regard as most essential, and now that colored pictures of a very interesting and pleasing nature can be obtained cheaply, there is no reason why every company should not make its barrack-rooms homely and comfortable."*

"We pay our men so wretchedly that we can only hope to entice men to enlist by making them happy whilst they are with us, and the first step towards happiness is to make men's dwellings bright and cheerful. We have done much in recent years to improve the condition of our men, but much, very much, remains to be done."

60. *Punishments.*—One last word, about the question of punishments. When I first entered the service soldiers were continually being tried for habitual drunkenness. I used to keep ready in my room dozens and dozens of court-martial certificates, and the regimental court-martial had lost its prestige because it was doing the work that the Commanding Officer since is doing so much better. What was the result of the system? You put a man in prison, and you put his work upon his comrades. I would say to you that, so far as my experience goes, long terms of imprisonment have done enormous injury to the soldier. When he comes out the man has lost strength, he plays about between you and between us—he is here, he is in prison, he is in hospital. I think, myself, the finest sys-

told the drunkenness was a tremendous loss, because the man went back at once to his duty—he did not throw it upon his comrades—and to his rations; and I am sure he was a better man than he was made by long terms of imprisonment, and I hope the day will come when you can get rid of those long imprisonments out of the army.

61. Long terms of imprisonment in Indian military prisons, often for unimportant crimes, act with highly injurious influence on the soldier's health and life fitness for the battle of life after the soldier leaves the army. I cannot think that anything more than one year's imprisonment should be given to a soldier in an Indian military prison—for if you do give him longer terms he becomes so enfeebled as to be liable to all tropical ailments, and eventually he is thrown on the English labor market, weak and broken down, and sinks into the useless soldier tramp, whom we all know so well.

I hope the day is rapidly coming when simple expulsion from the army will in itself be a most serious punishment, just as the expulsion of a constable from the police force is a real blow to any man who undergoes it. The least rise in the soldier's pay will tend to bring about that happy consummation.

I would say, finally, that we want above all things to combine in this work. I have no power to speak in the name of the medical service; but I say emphatically that our whole desire is that every want you have should be met. If up to the present time there have been troubles and difficulties in the initiation of a new system, I would beg you to remember that our whole aim is to come back to you and to do more for you than the regimental doctor ever did, but we must remain a unified corps.

THE DISCUSSION.

The Chairman—We shall all agree, I am sure, that we have heard a most interesting lecture which has covered so many points that I really do not know what to mention out of them. I do not know whether any officers have any questions that they would like to ask, but I am sure that Colonel EVATT will be very pleased to reply to any points that may be put to him. What he has said will lead us, I hope, to co-operate with the Medical Officers in many things—in some matters, of course, we can do nothing. We cannot give the soldier 3,600 cubic feet of air but we can bring our influence and opinion to bear upon the state of the barrack-room. Certainly one learns from Military Attaches and others that the barracks of the Russian and Prussian Guards are far ahead of our men's barracks.

Major F. A. YORKS—There is one point only that I would like to mention with regard to what Colonel EVATT said about a soldier's dining-room. In the Riding Establishment we have been very fortunate. It is not any credit to myself, but circumstances have so happened that I could get a dining-room where the men all sit down with a white oil-cloth put over the barrack tables, and we were allowed to get carving knives and forks and all the little things that make a dining-room look comfortable. The consequence is that men sit down there every day to something more like what they would in respectable civilian life, and that has had a great effect. I notice when I go round the rooms inspecting them that there is a great

absence of that nasty sort of faint smell of food that there used to be in the barrack-rooms, and the men certainly appreciate it very much. It is, I repeat again, no credit to myself, but circumstances so happened that I got a spare room given to me for this purpose.

The Chairman.—It only remains for me now to thank Colonel EVATT on your behalf for his most interesting lecture.

ANCHYLOSTOMA DUODENALE: IS IT WIDESPREAD IN INDIA, ASSAM AND CEYLON, AND IS IT A HARMLESS OR A HARMFUL PARASITE?

By HATMAN THOMAS, M.B.

Senior Medical Officer, North-Western and Sabaragamuwa Provinces, Ceylon.

FROM a public health point of view, it is a matter of vital importance that these questions, which concern the health, labor and lives of millions of people in Assam, Burma, Ceylon and India, should be carefully sifted, and if there be any who are not prepared to believe it is a harmless parasite, let them say so with no uncertain sound, and let them suggest the steps to be taken to mitigate its effects and limit its spread.

In the face of the havoc it caused among the St. Gotthard Tunnel workers and the Cologne brick-makers, or the damage it did in Borneo, Brazil, Cochiti, Egypt, &c., and after all that has been written about it by BILHAES, DUBINI, GRIENINGER, HIRSON, LEICHENSTERN, LUTZ, SONNINO, WERCHERER and many others, is it possible to doubt that, when present in large numbers for a sufficient period of time, this parasite causes a specific and fatal anemia? Can any one, who has held a post-mortem on an anemic cadaver and seen hundreds of these parasites clinging, like veritable blood-sucking leeches to the intestinal walls by their teeth which are so firmly imbedded in the tissues as to require some force to pull them off or looked upon the scars of what are manifestly old bites, still maintain that these are harmless intestinal parasites? Will they not rather agree that (1) the anchylostomata or dochmius duodenale is one of the most harmful and dangerous of human parasites, which (2) when present in the intestines in large numbers and for a certain period produces a specific and dangerous anemia (3) which should in future be known by the name of anchylostomiasis, to distinguish it from true beri-beri which (latter) is characterized by the presence of neurotic symptoms?

That it is widespread in India and Assam is amply proved by Surgeon-Major DOMON and Dr. MCCONNELL. The former, who examined the faeces of 1,949 natives of India, drafted from 85 districts of 9 provinces, found small numbers of anchylostomata in 75.66 per cent. of them; while the latter wrote to the *Lancet* in 1882, demonstrating its extensive prevalence in India, and Surgeons-Major GILES and MAX CAMPBELL, with almost all the Assam medical officers, tell how the parasite is spread to a large extent over the tea estates and to a lesser extent amongst the villages of Assam.

In his special report of 1886 on "Beri-beri (an unfortunate term) or Anemia of Ceylon," we well see in his

Annual Report of subsequent years Dr. KEMER, the Principal Civil Medical Officer, shows how prevalent it was and is, while Dr. MACDONALD does the same thing in his foot-note in the translations of BUCHNER, ENZI, LEICHTENSTERN, LUTZ, &c., in the *Ceylon Journal* and the Ceylon Medical Report for 1893, showing 1,760 hospital cases, with 395 deaths and 2,364 cases treated at the dispensaries (alternate results unknown) is hardly definitely conclusive of actual extent of prevalence since it is a common practice with many medical officers (who still do so) to return cases of this disease as malarial cachexia, diarrhoea, debility, dropsy, anaemia, &c., according to the most prominent symptoms, but without having examined the faeces for ancylostoma ova or adult parasites, whose presence they did not even suspect in many instances of severe anaemia, much more search for them.

From September 1892 to December 1893, the faeces of every patient admitted for marked anaemia into the hospitals of the Uva Province (160,000 population) were microscopically examined with the result that these parasites were found in such numbers in 118 children and 655 adults (i.e., 572 males and 211 females or 783 cases) and under such conditions as to justify their being diagnosed and returned as cases of ancylostomiasis; but it must not be imagined that the parasite and its resultant anaemia are confined to immigrants from India, since the nationalities of these 783 cases were:—231 Sinhalese, 45 Ceylon or indigenous and 470 immigrant Tamils, 95 Moors, 1 Malay and 1 unclassified. Whether this disease existed among the Sinhalese in past times or not would be almost impossible to ascertain, but the fact remains that it is now widespread among them in the Uva and other provinces of Ceylon, especially where Indian immigrants are employed on the estates.

Drs. SANDWITH and SONZINO have shown how prevalent and destructive this parasite is in Egypt, where about one quarter of the population is seriously affected by it, and where it is so "sapping the life of the peasant class" that 3·3 per cent. of the adult males of Upper Egypt and 6·2 per cent. of those of Lower Egypt were rejected as being unfit from *advanced anaemia* to serve in the Army, whose Recruiting Officer, an Englishman, rejected those only who were obviously too anæmic to serve with the colors; but accepted many who were already the hosts of this blood-sucking worm. In one province alone, Menoufieh, as many as 13·9 per cent. of the applicants were refused military service on account of this anaemia.

GILES and the Assam medical officers have shown that the parasite is very prevalent among the tea estate coolies in Assam, and that it is not unfrequent among the villages in Assam in the vicinity of estates, and DONSON declares:—"The indigenous population of the Dhubri district seem to have the parasite equally prevalent amongst them," while the Ceylon Returns and Reports show the same prevalence amongst the estate laborers and villagers, and even if it could be shown that it is not at present equally prevalent or destructive to life and labor in Assam, Ceylon or India, is there any reason to conclude that it will not become so, unless energetic measures be taken to limit its spread, and is it not the duty of this large and important Indian Medical Congress to urge on the Government the necessity for such steps

being taken and to indicate what those steps should be?

Reviewing Dr. DONSON's remarks in the Assam Reports, the *British Medical Journal* of 7th October 1893 says:—

"But we submit the ancylostoma is not the innocuous parasite Dr. DONSON's remarks tend to make it out to be: that, on the contrary, as the researches of many able men in Egypt, Europe and America have established, it is the cause when present in large numbers and in particular circumstances of a distinct disease, and that it is a powerful contributor to the mortality in such countries as India. We think therefore that he goes too far in minimising the pathological rôle of ancylostoma duodenale, and we trust that his views on this point may be received with caution and may not be allowed to interfere with the prophylactic and therapeutic measures his researches so plainly indicate."

Dealing in Assam only with those immigrants from India who had left their villages and were on their way to labor on estates, Dr. DONSON saw only the picked coolies who, when they left their homes, were well enough to travel, but certainly did not represent the average as regards effects from this parasite of all the inhabitants of the villages in India from which they came. It would have been correct and more reasonable to conclude that in the villages these infected immigrants came from there were many others who were and many more who would soon be, infected with larger numbers of this parasite, and that they either did or would soon reach that stage of infection when from larger numbers or from longer residence in their intestines of smaller numbers the characteristic anaemia and debility did or would appear, and had Dr. DONSON only followed up his researches by visiting the villages, &c., from whence came these "healthy coolies, the cream of the population," he would not only have found numbers of persons in far advanced stages of anaemia and debility with not 5, 10, 50, 100 or 150 only but hundreds or thousands of ancylostoma and the sickness and mortality that results from them, but also would neither have written: "These results (page 52 of Assam Reports for 1891) are astounding as they prove beyond doubt how very extensively the ancylostoma is distributed over India and with practically no bad results" "where (page 68) 65·38 per cent. of the cream of the imported population is literally teeming with the parasite" nor asked "Why should not the ancylostoma prove equally fatal in other parts of India?"

Then on page 66 of the Assam 1892 Report he says:—"In true beri-beri (he means ancylostomiasis), it is often found in trifling numbers, and again in absolutely healthy persons it is found in great numbers;" but he neither quotes actual cases nor gives their medical history or particulars of how often their faeces were examined, nor does he say whether his remarks were based on the number of parasites present during microscopical examination of the faeces for ova, or on the number of parasites found after only one administration of thymol. Even supposing that he did repeatedly examine even a fair number of bad cases, he would not be justified in concluding that the condition was not due to the ancylostoma; for GILES, LEICHTENSTERN, LUTZ and others have adequately proved that in many cases the severity of the symptoms bears no relation to the number of parasites present at any particular time, and that the number of parasites found

to-day affords no sort of indication as to what numbers of parasites were present previously.

Leading into Dr. Donson's remarks and tables of the results of his examination of "hundreds of healthy-looking coolies and other persons" the vast majority of the cases exhibit under 50 ancylostomes—a number altogether too small to have any deleterious effect—while in only seven cases do the numbers reach or exceed 100 of these parasites, and it becomes evident that he has not carefully determined and considered (1) the minimum number of parasites that will cause any symptoms after a protracted sojourn in the intestines, and (2) the length of time in the intestines that is necessary for even a large number of the parasites to produce annular or other serious symptoms: For had he estimated the numbers from the ova or treated the cases with thymol for more than one day and examined the stool on the first, second and third day after the thymol, he would surely have found much larger numbers of the parasites than he says he did. Dr. Donson is therefore not justified in inferring or in asking the authorities to infer, as apparently he does, that because these coolies appeared healthy, notwithstanding the presence of the parasites even in large numbers (100 to 250) that therefore these parasites are harmless; for he has omitted to state or to even take into consideration the length of time these parasites were in the intestines of these coolies.

LUTZ has shown that when an exposed person tardily acquires this disease, the ancylostoma may be very limited for a long time, and their presence give rise to no symptoms whatever, while in the absence of complications, adults, in whom the disease runs a tolerably rapid and uniform course, seldom exhibit symptoms till the number of parasites passes into the hundreds, so that, when pronounced general symptoms are present, there may be from 500 to 500 ancylostoma in the duodenum. In severe cases LUTZ did not find over 1,000 present, but in the Gotthard Epidemic as many as 2,000 and even 3,000 were found in one patient, and LEICHENSTERN (*Ceylon Medical Journal*, January 1892) found 253 of these parasites, in the bowels of a man who died of phthisis pulmonum four weeks after infection with ancylostoma, but who never had any intestinal symptoms and no signs of any special anemia. GILES makes similar remarks in the *Indian Medical Gazette* of July 1892.

However faulty his deductions in other respects, Dr. Donson's figures do show the parasite to be most widely distributed, and that the affected persons had been, were, and would be, a direct source of danger to others as they were sowing the ova of this parasite to infect others or still further infect themselves for no matter how few parasites are present in any one, each person's stools must contain thousands of the ova, and if they defecated on the surface of the ground, they undoubtedly spread the parasites to others, and of course those left behind in the villages were doing the same.

On page 80 of Volume I of the *Transactions of the 1891 International Congress of Hygiene*, Sir A. FARRAR says:—"Preventable disease still kills yearly about 125,000, and considering the large number of cases for every death it

has been calculated that 750 millions of larvae are deposited annually, which means 277,000 per annum" (p. 80, 1891, 1900 or Rs. 22,40,00,000); while on page 249 Dr. LOWMAN writes:—"Thus in *anncylostomiasis*, *filaria*, and *bil-haria* are veritable scourges to mankind—scourges of a kind that do not destroy at once like cholera or plague, but decimate slowly and deteriorate entire populations like malaria. To these scourges particularly I wish to call your attention with a view to devising means for their prevention." "I do not exaggerate" (*Ceylon Medical Journal*, April 1896) in saying that it (*anncylostomiasis*) is a social plague only second to malaria and pellagra. It is also easily dealt with and may be prevented by simple means, and fortunately in the gravest form it is limited to certain workers. I may also say that it would not be impossible to destroy the fecal altogether: let us do what lies in our power to attain this object, and I request your valuable assistance in this direction."

As regards extensive prevalence and destruction of life and labor, ancylostomiasis is second only to malarial fever, and in a way is almost more important, as it is most prevalent in the estates, basars and larger villages which are comparatively free from malaria, and to which people have ascended to escape from the deadly malaria of the low country, and it may therefore be said that ancylostomiasis substitutes the terrible malaria of the sparsely populated low-lying unhealthy divisions, and is almost equally prevalent and destructive in the higher portions of the provinces which are comparatively free from malaria. Hence it is imperative to check this widespread destruction of life and labor by penal enactments, preventing the pollution of the ground about dwelling on estates, &c., by the provision and proper cleansing of sufficient and suitable latrine accommodation and other sanitary measures which, though necessarily tentative owing to the ignorance and prejudices of the people who are to be benefited, must be the very minimum that science, reason and experience indicate as necessary to limit the spread, and mitigate the evils of, this terrible disease; so that the expense to Government and the interference with the people and their habits may also be the minimum actually necessary.

Whether there be a rhaditis stage or not, or whether the larvae enter the intestines from the soil directly or from water matters but little as regards the steps necessary to prevent the spread of this parasite. If the infection be water-borne, which is hardly likely, it takes its infective properties from the soil, the proper step is to prevent the soil being infected. Similarly, if the infection be direct from the soil either by encysted larvae in the free stage or by the parasite in a rhaditic stage, the only possible step is to prevent the feces of persons, infected with the parasite, being scattered over the surface of the ground. This can only be done, by the use of properly kept latrines.

French latrines may do well enough for an Army on the march or for temporary gatherings of people, but they require too much space to be dry sufficiently near the houses of those expected to use them, and are also open to the risks of business or other prejudices leading to

their own long hair, and over daily with earth, (3) of children, especially defecating on their edges or on the ground near about them, rather than inside them, (4) of the large numbers of latrines being worked on the feet of the Government, and of cows, dogs, etc., into the houses of the inhabitants, and (5) their clothing being rarely washed out, during the rainy weather to pollute the water supply. The ordinary permanent bucket latrines are too costly to erect on a large scale and much too expensive to keep constantly clean and fit for use, and undesirable though omits are, the only alternative is the pit latrine, which is simply a long narrow deep pit with old railway rails and iron footplates over the top. The people should be led and induced, rather than compelled to use these latrines which should be constructed in sufficient number and propinquity to not involve too much trouble to the inhabitants to go to them, and if only a half or even one quarter only of the inhabitants used them, there would be an enormous improvement and advantage which would to that extent limit the spread not only of this but also of other diseases such as cholera, typhoid fever, &c. Power should, however, be created to punish any one himself committing, or allowing any one else to commit, a nuisance within 100 yards of his own or of any other house; but such powers should seldom be used.

The water supply, at its source, along its course and where delivered, should be protected from pollution and the natives encouraged to boil all their drinking water, so as to guard against parasitic diseases, cholera, malarial and paludal fevers, filariasis, &c.

As early cases of anaemia can be recognized by a doctor long before the patient is aware that he has a definite illness and as a single dose of thymol can prevent the chronic pernicious anaemia that drags a man, too late perhaps, to the hospital, one, two or three years after he begins to feel ill, all recruits for the native army and police, all Government coolies and native employees of all kinds, all children in Government schools and all estate laborers and factory hands should be examined more carefully than is at present done for the early symptoms of the disease, and if it existed in any marked degree, the sufferers should be detained and their faces microscopically examined for ova, and if found, the person should be detained for further treatment and his village or possible place of infection registered for inspection, as far as possible, of the inhabitants of such places or villages with a view to similar examination and treatment if cases of anaemia be found among them.

That they will submit to periodical examination and treatment should be made an imperative condition of continued service with all Government native employment and with all estate and factory hands coming from or working in infected areas or having been at one time affected with *echinostomiasis*, and numerous dispensaries should be, even temporarily, opened in all villages and places known to be centers of this disease and the inhabitants should be urged to have themselves treated by medical subor-

dinates, specially made familiar with this disease and the use of thymol and male fern.

The following abstract of cases treated by (1) thymol alone, (2) male fern alone and (3) male fern one day and thymol the next, is really instructive:—

		Treated with			Total.	
		1 Thymol.	2 Male Fern.	3 Both.

	Deaths	...	48.84	48.78	4.87	...

The male fern was administered in 1½ drachm doses and the thymol, which was triturated and suspended in water to minimize absorption or prevent it altogether, was given in two 30-grain doses with two hours' interval between the first and second dose. Half or a quarter only of these doses were given to children or to weakly adults. The above figures would indicate that alternate doses of the drugs would ensure the best results, and that male fern is superior to thymol; but the results are, however, too close together to furnish data for preferring one drug to the other: except that besides being intensely disagreeable to take, thymol is a very dangerous drug. Its horrible taste and the burning excitement, giddiness, fainting and even vomiting, which it not infrequently produces, render patients loath to take it and many absolutely refuse the second dose. LEICHENSTERN records one case of fatal collapse due to thymol. SANDWITH records two, DOBSON one or two, and the writer of this note has to add three more cases to its list of mortality, as well as to add a word of caution against administering thymol in spirituous solutions or giving brandy or other spirits abundantly after its administration. 30 grains of thymol, suspended in water, was given to a male patient at 7 A.M. As he exhibited no special symptoms after it, the nurse gave him his second dose of 30 grains at 9 A.M., at which time he was also supplied with a portion of the arrack he used to get at 9 A.M. as an extra, and which he swallowed immediately after the second dose of thymol. The result was that intense collapse set in almost at once, and in spite of all efforts to save him, the man died within 24 hours—the collapse manifestly being due to the arrack dissolving the thymol which was thus absorbed.

INFLAMMATION OF THE BLADDER. SOME
POINTS IN ITS TREATMENT.*BRUNNEN.—CAPT. F. J. CRAWFORD, M.D., M.CH., D.P.H., I.M.S.
Madras.

This is not an uncommon affection in India, and the unsatisfactory character of its treatment induces me to make a few suggestions based on some cases recently under my care. The first thought occurring to the mind in reading through the literature of the subject is the extremely varied nature of the remedies recommended by different authors. Sedatives, stimulants, acids, astringents and antiseptics, internally by mouth and by vesical ablation, have all been at various times lauded in the treatment of this troublesome affection, their mere enumeration would fill many pages. Most of them, if not all, have, I contend, been recommended on inadequate grounds, and errors must have frequently crept in when appealing to statistics to prove their utility. The broad principles involved have not apparently been recognised, the necessary accompaniments to treatment have not had sufficient importance attached to them. It is by no means rare for a surgeon to spend care and discrimination in selecting his own pet lotions in their order of value, and finally to select what he thinks is the particular one which cures his patient. This remedy holds the field till the next case of the kind comes under his care, when he finds that the whole process must again be gone through. The result is naturally disappointment and a fixed belief that the more such cases are permitted to avail themselves of the orthodox rest in bed, bland diet and *vis medicatrix nature* the better, though months must pass before distinct improvement sets in. Patients under these circumstances lose all faith in doctors and drugs, they wander from one medical man or institution to another, trying in passing a course of quack remedies which probably touch up slumbering chronic inflammation, and start renal troubles which attend them to their dying day.

Cases can be divided into two classes—the acute and the chronic. The acute cases, as a rule, do not present difficulty after careful exclusion of exciting causes, such as stone, kidney and prostate diseases, which must of course be treated before the bladder is capable of returning to its normal condition; while ordinary means readily relieve the pain, spasm and want of rest. Knowing, as we do, that the inflammation is more severe at the region of the trigone and consequently in close proximity to the sphincter, position with the pelvis raised most of the day, suppositories of opium and camphor with alkalies internally and leeches to the perineum will quickly control the serious symptoms. Vesical ablation is not generally advisable at this stage; if anything, plain water, which has been boiled, should alone be used. Under no circumstances should strong lotions be injected, whether astringent or antiseptic. Dilute solutions of cocaine might perhaps be of benefit in some bad cases, but I have found that the greatest pain is experienced when the sphincter spasmodically contracts, that is at the area of most acute inflammation both before and just after micturition—at times in fact when a local application of the drug is practically

impossible. The bladder is in a highly irritable and contracted state and resents local interference of this character. The urine should be maintained in a normal condition and the liver and bowels frequently relieved by blue pill aloes and senna. The very acuteness in character of the symptoms gives us small scope for individual preference in the choice of remedies, general principles will be followed by anyone in overcoming their urgency. Regarding the use of the catheter, no rules can be laid down, each case must be treated on its merits, none should be passed however but rubber ones. Hot fomentations above the pubes and at the perineum are often of great benefit when the pain is severe. If bleeding should occur, it is if anything rather beneficial than otherwise.

It is when these cases lose their urgency and become chronic that they also become so intractable. During treatment patients are frequently permitted to walk about and resume their avocations, with probably some simple directions regarding food, diet and personal hygiene. The disease becomes confirmed and remains a source of annoyance to the patient for years and gradually converting the strong, healthy man into an invalid. He is willing, when periodical exacerbations occur, to lie up for a few days, perhaps a week, but on account of the usual unsatisfactory nature of the treatment along with, in too many cases, want of decision on the part of his doctor, he resumes his own way when temporary relief is obtained. In few cases I think is the distinction between *treatment* and *drugs* seem to such an extent as in the management of chronic vesical inflammation. The drugs and applications which are curative in one case will fail utterly in another for want of due appreciation of this fact. The system must be prepared for a systematic course of treatment. The digestion, which is often at fault, must be brought into order before special lines are followed; the state of the tongue, stomach and bowels must be looked to, and general evil tendencies corrected. It is not enough in these cases to simply purge our patient and give him a little tonic for some days. Assimilation will be judged by the character of the urine, by the general condition, and the presence of nervous troubles like headache, neuralgia, eye and ear symptoms and subjective sensations generally. A week or ten days at least must be allowed for this preliminary course. The giving of such special drugs as vesical sedatives and stimulants, salol &c, when a patient's digestion is out of order, as well as the internal economy generally is unscientific. This fact is emphasized during a satisfactory course of treatment in the way the bladder responds to such troubles when incidentally arising. A foul tongue will almost infallibly be found to be accompanied by relapse locally, so will an over-loaded bowel, so will a cold skin or cold extremities or a sudden chill. The irritable bladder seems to be acutely sensitive to internal troubles of other organs, due probably to changes in the character of the urine when increased waste products of an irritating character are present in it.

Our first efforts then must be directed towards impressing on patients the necessity for a prolonged course of treatment of which rest in bed is an essential part. At the same time we can assure them that if directions are

* Read before a meeting of the South of India Branch of the British Medical Association and sent to the Record for publication.

During treatment in every way, the patient's comfort will be carefully followed. This constant attention on the medical attendant's part will prove of great value when depending on what must always be a tedious time for both doctor and patient. Confidence is justified in the fact that careful inquiry will elicit in cases of relapse, some neglect of apparently trivial orders. As long as the patient proves amenable and manages to divert his mind from his troubles, the course of the complaint will be progressively favorable. We must constantly supervise and vary the diet while keeping it of evenly unirritating and digestible kind. Milk is well borne in most cases at first, but later on it becomes distasteful, and therefore harmful if not varied and occasionally stopped even though for a day or two. The tongue is here our best guide. The skin should be kept uniformly warm, mild diaphoretics will be sometimes useful, in draughts rather than mixtures given in the late afternoon. The bowels and rectum will naturally involve daily inquiry. This detailed treatment is impossible without a good nurse during the day, and if possible, at night. Regular notes should be made to guide the doctor as to the amount of food taken, the medicine, and all other events during the twenty-four hours. Temperature should be taken in the mouth, any rise above 99° or so being a signal for extra attention. The number of times urine is passed, the character of the pain and when felt, and disturbance of rest are all of importance. If the pelvis is kept raised on a pillow, relief is sometimes marked, and the patient will voluntarily assume that position whenever he lies down. The pain is of a two-fold character, either due to spasm of the sphincter from close proximity to a focus of inflammation or to spasm of the muscular wall of the contracted bladder. The first occurs just after micturition, and is referred by the patient to the perineum, the other occurs just before micturition from distension of the organ; it may be present off and on while the patient is awake and will wake him up at night in order to relieve himself. The urine is always passed very frequently when patients come under observation, as many as thirty times in the chronic forms of the disease. This is gradually reduced by treatment to fifteen, then to ten, and finally before passing from under observation the urine can be retained all night. After rendering the urine neutral in reaction by appropriate drugs—buchu infusion with hyoscyamus increases greatly the amount of urine and for a time (as much as a week), the urine is passed more frequently still, while the urgency of the actual pain becomes relieved. Salol is useful if the urine is of an irritating character. Copaiba, cubeba and turpentine will increase the urine and may be given in some cases for short periods. Smoking should be absolutely prohibited. Cold compresses will be found useful if applied above the pelvis to relieve the pain before and after micturition. Similarly with hot fomentations, so useful in acute cases.

The question of washing out the bladder has given rise to much discussion, and every possible antiseptic has been tried and with varying success. In chronically inflamed bladders, there is always contraction as well as spasm. Although the bladder is painful when distended by fluid inside, it apparently does not experience pain when irritating fluids like boric acid lotion is injected.

distension, however, does occur, and washing with such acid washed is quite a solution. There is the same objection to strong solutions of silver nitrate. If the experiment is tried in the same case with weak boric acid lotion and a very little diluted solution of permanganate of potash, it will be found that the bladder can hold at a time twice the quantity of the permanganate. If the latter only be used, the bladder each day will gradually be induced to tolerate more and more till in a week six ounces can be retained when half that amount of urine must at once be got rid of. The object of this lotion is to accustom the irritable contracted bladder to retain a gradually increasing quantity of a bland lotion, on the same principle that full-sized catheters are passed into a urethra in a similar state. Besides its tonic effect on the muscular wall of the organ it has an alterative effect on the mucous membrane. This preparation of the bladder, to resume its healthy function and retain its normal quantity of fluid, is one of the most important parts of the local treatment. The urine, no matter how bland we make it, must always be irritating to an inflamed bladder, and it should be passed immediately there is inclination. No object is gained in getting a patient to retain it, gradual distension must be done with weak permanganate. The process consists in fact not so much in washing out the bladder (the washings after the first one are usually clean) as in this education, as it were, of the organ. In connection with this subject of bladder ablation, a fallacy is likely to creep in and mislead the surgeon as to the source of mucus-pus in the urine unless the cystoscope is used as a means of diagnosis. In inflammation the urine, on standing, yields a sediment, varying from the light flocculent thready mucus of the long-standing case to the pus of the recent one. Though the deposit is quite apparent, it will be frequently noted that washings come away quite clean if the operation is undertaken after micturition. This is due to the fact that pus cells and mucus are gradually detached from the bladder wall and between times of micturition sufficient matter comes away to give the urine its characteristic appearance. The simple washing does not extend over a sufficient time for this to happen. The cystoscope readily shows this condition, semi-detached shreds are seen on the bladder wall, which gradually mingle with the lotion and presently obscure the mirror, leading to the supposition that their source is higher up.

In the foregoing remarks I have attempted to point out the difficulties experienced in treating inflammation of the bladder and some fallacies likely to arise during its course. The disease will always prove troublesome in spite of remedies and too often our efforts are not supported by the patient who considers that the individual skill of a particular surgeon is of greater moment than his own intelligent acquiescence during a necessarily tedious period. With general attention to the system however and local treatment of the mildest nature, I have found that improvement is progressive and certain, though gradual. Operative treatment such as cystotomy, I look upon as quite unjustifiable except for special reasons; it should not form a necessary part of the treatment. More than that it is unscientific, since nothing is gained by it except for the moment and later on it becomes a troublesome complication.

N.B.—At the meeting Surgeon-Colonel BRANFOT alluded to the value of solution of morphine in relieving pain and spasm.

INTUBATION IN DIPHTHERIA.*

By W. K. SIMMON, M.D.

*Surgeon to the New York Eye and Ear Infirmary;
Instructor in Diseases of the Head and Throat
in the College of Physicians and Surgeons,
Columbia University.*

THE advent of intubation for the relief of diphtheritic croup marks one of the greatest achievements of modern medicine, and in connection with the antitoxin treatment materially lessens the mortality in diphtheria, as well as robs one of our most fatal diseases of its horrors. To Dr. O'DWYER is due the honor of replacing tracheotomy by intubation which, to use his own words, he was led to employ because of the "complete failure with tracheotomy in the New York Foundling Hospital, extending over a period of several years."

Tracheotomy, even with its high mortality, was the recognised operation for laryngeal croup and as surely as no new operation to supplant a well-grounded procedure—however faulty—can thrive without passing through the crucible of criticism and severe testing; intubation, which has now rendered tracheotomy practically obsolete, was at first received with a great deal of scepticism, suspicion and opposition, all of which it has successfully overcome and its real battle waged and its glories were won long, long before the days of antitoxin.

The question of when to operate is always of vital importance, and especially so if antitoxin has not been employed; as in 60 per cent. of the cases of laryngeal diphtheria intubation is not required if reliable antitoxin has been properly administered at any early stage of the disease. If croupy symptoms supervene and progress the antitoxin should not be discontinued and the croupy symptoms be carefully watched, remembering that it sometimes requires 24 hours for the full effect of the antitoxin to be manifested: this is especially important if the symptoms of laryngeal stenosis are the first indication of the presence of diphtheria.

In either case the initial dose of antitoxin should be a full one, and if the symptoms of stenosis are progressive, intubation should be immediately performed: never in any instance wait for the severer symptoms of stenosis. After intubation, and until the membrane shows a marked tendency to foliate and the respiratory symptoms a tendency to disappear, the use of the antitoxin should be continued in gradually decreasing doses till the pulse temperature and other conditions become normal.

The technique of the Operation.—The proper-sized tube having been chosen and threaded with a piece of braided silk long enough to be looped over the patient's ear when the tube is in position. Two assistants are required, and both should be powerful men or strong women with cool heads. The patient sits on the left thigh of one assistant with his (or her) left side free and the right side pressed against the breast of the assistant who grips the patient's legs tightly between his own and passing his left hand round the patient's back secures his left arm and hand, while his right hand holds the patient's right hand firmly.

The second assistant stands at the back of the patient, holds his head in a suspended position (with the neck perfectly straight) and steady the mouth gag.

Standing in front and a little to the right of the patient whose mouth is kept well open, the operator passes his left forefinger into the larynx, over the epiglottis, till he feels the tips of the arytenoid cartilages, when he quickly passes the introducing instrument (i.e., the obturator) over the palmar tip of his left forefinger until the end of the tube engages deep in the larynx, when the tip of the forefinger is transferred to the head of the tube to keep it in position while the obturator is being withdrawn—care being taken not to remove the obturator from the tube until the latter is well down in the larynx, thus avoiding any danger of stripping off or wounding the mucous membrane.

Successful introduction of the tube is almost immediately rewarded by relief from the difficult breathing and the means of knowing that the tube is properly placed in the larynx are: (1) relief in breathing, (2) a characteristic moist metallic cough which immediately occurs and is valuable in clearing the trachea of secretions. This cough should always be looked for, and if not present, should be provoked by the administration of a teaspoonful of diluted brandy or whiskey. In moribund cases this cough may be delayed or very feeble when it is heard. (3) Passing the left index-finger down into the oesophagus and feeling the tube through the anterior wall of the larynx is of great service if the breathing is not fully relieved, and it is desired to be positive as to the position of the tube.

If the breathing is not relieved or becomes suddenly worse after the introduction of the tube, it is possible that some detached membrane has been pushed down with the tube. This accident, which is not frequent, is more likely to occur in late cases of croup, where the membrane has begun to exfoliate and at any time when traumatism has been caused by the introduction of the tube. It is accompanied by a flapping sound caused by the loosened membrane and excessive coughing to dislodge it. When this happens or the breathing is not relieved, the tube should be withdrawn by the string and the patient encouraged to dislodge the loosened membrane by coughing, after which a second attempt at introduction should be made.

If it is reasonably certain that loose membrane is blocking the tube and cannot be readily expelled, a short cylindrical (foreign body) tube, which is larger in caliber than the intubation tube, should be inserted, but it must not be left in the larynx for more than a few hours, owing to the pressure it causes.

Introduction of the tube into the oesophagus, which sometimes occurs, can be appreciated by (1) failure to relieve the difficult breathing and the patient's attempts to (2) vomit or (3) swallow the tube. If the string, which is attached to the tube, is observed to be disappearing down the mouth, it is evident that the tube is in the oesophagus and should be immediately withdrawn.

The tube may sometimes be swallowed when coughed up by the patient, or the end of it may be introduced into one of the ventricles of the larynx; but this latter accident may be avoided by keeping in the median line during in-

* Read at a meeting of the New York Academy of Medicine under the auspices of the Section on Laryngology and Rhinology and specially reported for the Indian Medical Record.

tracheotomy, and using the present type of hard rubber tube which bulging and pressure tend to override the ventricles.

After the tube has been passed, the string should be slipped, as a minimum in place—with the loop over the left ear—for 15 to 30 minutes, until quiet breathing is restored, when the string should be removed in this wise:—(1) Cut one side of the loop close to the mouth. (2) Exert gentle downward pressure on the head of the tube with the left forefinger (because the string becomes twisted in the mouth and unless counter-pressure be made, will entangle the eyelid and withdraw the tube) and taking hold of the long end of the string withdraw it with a gentle steady pull. Do not jerk it out.

How long the tube should be allowed to remain in the larynx depends on circumstances. In the pre-antitoxin days the average period was six to seven full days, but under the present mode of combined treatment the time varies from three to five days, though in a very small percentage of cases, after the original malady has ceased to exist, a more or less permanent stenosis necessitates almost constant use of the tube for periods varying from a few days to some months. Paralysis of the vocal cords may possibly furnish an exceptional cause of this persistent stenosis (following intubation in laryngeal diphtheria) which is almost invariably due to traumatism from injury to the larynx by (1) an ill-fitting or (2) imperfectly constructed tube, or from (3) a perfect tube which is too large for the lumen of the larynx, or from (4) a well-made and perfectly fitting tube that is not cleaned at proper intervals. The seat of the lesion, which keeps up this stenosis, is just below the vocal cords in the subglottic division of the larynx or that portion bounded by the cricoid cartilage; but exceptions to this rule result from injury produced by the head of the tube on either side of the base of the epiglottis just above the ventricular bands.

The hard rubber tubes now in vogue can not only be worn indefinitely without the occurrence of the calcareous granules which, appearing on the metal tubes, often became foci of ulceration, but their impinging points also do not produce the same degree of pressure as do the metal tubes.

The chief indication for removing the tubes previous to their final removal are severe discomfort or pain from pressure—if the pain be radiating in character it indicates the presence of ulceration—, severe attacks of coughing and sudden stenosis due to lodgment of membrane in the lumen of the tube. This last is more likely to arise earlier under antitoxin treatment, which causes earlier exfoliation of the membrane and in some instances, where it does not fit tightly, the tube is likely to be coughed up with the loosened membrane. The necessity for re-introducing the tube—in such a case—does not always arise or at any rate it will, as a rule, be sufficiently delayed to permit re-introduction by the physician in charge.

Feeding after intubation should be restricted to fluid or semi-solid food, and is best accomplished in the Cassel-berry position, which consists in keeping the patient in an inclined position, with the head down, effected by raising the foot of the bed and supporting the pillow—and feeding through an ordinary duck-shaped feeding cup, so as to

prevent fluids entering the tube and causing paroxysms of coughing. If the patient cannot swallow conveniently, he may be fed through the oesophageal catheter passed through either the nose or the mouth, or as a last resort rectal alimentation may be employed.

To extract the tube the patient must be placed in the same position as for its introduction; but the operation is more difficult since it requires a finer degree of touch to determine the opening in the head of the tube, and the difficulty is enhanced in proportion to the emphysema of the tube. In extracting the left forefinger is passed down till the opening in the head of the tube is felt and then the 'extractor,' with its joints closed and thumb-screw so set that the proximal jaw can open just sufficiently to exert the proper amount of pressure within the opening in the tube, is passed down till its point strikes the head of the tube and enters the opening in front of the tip of the finger, when the joints of the instrument are opened by thumb pressure on its handle and the tube withdrawn.

Where an extractor is not obtainable, or in cases of emergency when the tube must be removed by the nurse in the absence of the surgeon, slightly invert the patient, whose mouth must be kept wide open, and placing the thumb in the episternal notch push the tube up into the mouth where it may be grasped with the fingers of the free hand or with a pair of ordinary forceps and removed.

After removal of the tube the patient should not be left until there is sufficient evidence that the tube will not have to be replaced. A small opiate may then be given to allay cough and irritation. Slight cough and hoarseness generally continue a few days to a fortnight and pass away without incident.

The prognosis under combined intubation and antitoxin is remarkably favorable, especially when compared with the results formerly obtained, where 69.5 to 75 per cent. of mortality is now reduced to 27.24 per cent., and there is no doubt that the prognosis will continue to be even more favorable as there is gained a better understanding of the combined treatment.

It is most important to watch the respirations during the entire period of intubation as bearing on the progress of the disease. If they continue normal, or nearly so, favorable progress is indicated, but if they show a tendency to increased rapidity, extension of the membrane is indicated—fortunately this latter does not occur as frequently as it did in pre-antitoxin days.

In a very small number of cases intubation fails and tracheotomy becomes necessary; but the percentage of recoveries, when this has been done, has been small indeed and conditions have been found which could hardly be reached by either operation.

In conclusion, intubation has not only given us a comparatively simple means of combating a dreadful emergency and taught us exploration of the larynx by the finger, but by teaching the mind and hands to work in quickest harmony; it has also taught us alertness and deftness in meeting emergencies, as well as opened up and created anew the treatment of the entire domain of laryngeal stenosis.

A MIRROR OF PRACTICE.

THREE CASES OF LIGHTNING STROKE AT DARJEELING: RECOVERY.*

By SURGEON-MAJOR R. R. H. MOORE, M.D., T.D., A.M.S.
Jalapaahar, Darjeeling.

On the 29th March 1898, my wife and I and a native servant were struck by lightning in our house at Jalapaahar, Darjeeling, under the following circumstances:—

The house has a corrugated iron roof to which is attached two copper lightning conductors; these are connected with the ground at the back of the house. There is no connection between the iron roof and the ground in front.

The way in which the conductors are fixed on the roof is peculiar; they do not rise from the highest point, or ridge, but from the front slope of the roof about half way between the ridge and the eave; the connecting band then passes upwards over the ridge and down the back to the ground.

At the front of the house is a small porch, entered from the house by three steps; the eave of the porch is seven feet from the ground and the roof is a single layer of corrugated iron.

At about 4.30 P.M. we were all standing, with two dogs, in this porch watching a thunderstorm coming up the opposite valley. I was facing the glass door and quite close to it, the *chuprassi* was about a yard to my left, and my wife and dogs were on the steps behind, when, without a moment's warning, we were all struck down unconscious.

The unconsciousness does not appear to have been absolutely instantaneous, for both my wife and the *chuprassi* saw the other two fall. I first of all swung round to the left, then fell backwards; in doing so I saw the *chuprassi* also fall. I did not hear any report, nor had I any knowledge of what had happened until I recovered consciousness.

There was no one standing by to see what happened, so it is impossible to say how long we remained in this condition. My wife was the first to recover and called me, but at first I did not hear. When I recovered consciousness I heard her calling me. I then realised what had happened. I was very dazed and not in the least inclined to move, so I lay where I was, feeling and congratulating myself in a sort of wonder, that I was all right; though I must confess that the thought uppermost in my mind was a sort of sickly resentment against such an uncalled-for and unnecessary calamity. In the meantime the *chuprassi* was lying outstretched on the floor as if dead. The dogs had given a few yelps and run away.

Nature of Injuries.—My wife's right arm was paralysed and numbed for about ten minutes, after which it got gradually quite well, from an inch above the bend of the elbow straight down the front of the arm to the wrist there was a well-defined lightning mark, in the lower two-thirds of the arm there was a clearly marked arborescent pattern, in the upper part the line was single; the markings were red, like a burn of the first degree; it lasted four days.

* These excellent clinical notes of cases of lightning stroke are extremely interesting and are most valuable, as not only are they the personal experience of a physician, but they are so complete and perfect in all necessary details as to make their record quite unique, as instances of lightning stroke are rare enough an occurrence and still more rarely are they reported in this scientific manner.—ED., J. M. S.

In addition both feet were numbed, the nervous shock was very slight, and she hardly suffered at all from any after-effects.

My feet were also numbed; and I had the sensation of having received a very severe blow on the back of the head. I had two slight red marks over the right temple and one over the right eyelid. I suffered very severely from pain in the head and down the back, all that night; my eye was painful, congested and very irritable, and there was profuse lachrymation. The right side of my nose was swollen and gave the sensation accompanying catarrh.

My eye continued irritable and bloodshot for seven days; the irritability was relieved by dropping into it a weak solution of cocaine about every half hour.

The pains in the head lasted more or less for ten days; there was considerable nervous prostration at first, and I was easily fatigued by any mental or physical exertion; this slowly and gradually passed away.

The injuries received by the *chuprassi* were more serious: when I crawled over to him he was not breathing; the other servants were just lifting him, and he appeared quite lifeless. I thought he was dead; and, as a matter of form, felt his pulse; to my surprise it was beating steadily and strongly. At that moment he gave his first gasp, after a few irregular gasps his breathing became re-established. For a time he lay quiet, then convulsions came on, and three servants could hardly restrain him, while he uttered incoherent cries occasionally.

He was in this state for almost an hour before he recovered consciousness.

He had a well-defined triangular shaped burn on the forehead, extending from the outer angle of each eye to the centre and top of the forehead, over this area there was a burn of the second degree, and all the cuticle turned black and peeled off subsequently, both eyebrows and eyelashes were completely burnt away. The eyelids became very swollen, the eyeballs deeply congested, and there was a distinct whitish film over the left cornea, which, however, completely cleared up; the nose was increased to double its ordinary size.

Another burn extended, in a line half an inch broad, from close to the centre and top of the temporal bone round his face close in front of the left ear, then under the chin, then downwards again and to the right, where it ended in splashes about the right nipple, the hair along this line was destroyed, and where it began the whole thickness of the skin was burnt through. He also had a circular burn on his chest corresponding to the place beneath his brass *chuprassi's* badge.

He complained chiefly of pains in the head, back, shoulders and down both arms; there was profuse lachrymation from both eyes. Cocaine half a grain injected twice a day, gave more relief than morphia. The acute symptoms lasted over a week, they then gradually subsided; the congestion of the eyes was very persistent, though excepting the slight haziness mentioned, nothing could be seen to account for it.

The smell attending a lightning flash is generally described as sulphurous, it was not so in this case; it was the smell given off by red hot iron when a drop of water is thrown on it; the smell and taste remained with me for several days; it was perfectly familiar to me, and any one can reproduce it for himself if he likes to touch his tongue

with a rod the bar of iron, and a shock (this fact I have frequently mentioned).

In the same electric discharges, there would appear to have been two different shocks; one from the ground and one from the roof. I felt the tingling in my feet as the electric fluid was passing, but beyond the fact that I felt a vibration in the ground, I recollect nothing.

It appears to me that a strong charge of electricity must have accumulated on the iron roof which could not readily pass to the ground as there was no conductor in front, and that in making its way as best it could, some off-shoots or splashes struck us, our hands were not far from the roof. The dogs, I think, could only have been affected by the electricity in the ground and the shock they received was proportionately small.

I may add that none of us saw any flash.

A CASE OF TRUE PLAGUE TREATED ON ORDINARY PRINCIPLES.

By JOHN E. PANIOTY, L.R.C.P. Lond., L.M.C.P. & S. Edin.
Resident Surgeon, in charge Chandni Hospital,
Calcutta.

A HINDOO punkah coolie named SANU, aged about 17 years, was brought to the Chandney Hospital in a hired carriage from 8, Crooked Lane, at about 1-15 A.M. on the 13th May, and was admitted as an in-patient.

He was in an unconscious state, and when roused with difficulty, answered questions incoherently, relapsing into unconsciousness. He had a stupid and anxious look and from his mouth issued a viscid frothy mucous. He had all the appearance of a drunken person, and as if he had not slept for some days. His conjunctivæ were intensely congested, and did not respond to the touch. He lay on his right side with both legs drawn up, quite unconscious of what was taking place. He had a soft painful enlarged gland of the size of a walnut on his right groin which, whenever touched, seemed to give him a shock as if from a battery. His internal organs were in a healthy condition. He had involuntary stools and constant vomiting. His temperature was 108°6' at the time of his admission.

I asked Dr. SANDERS, the Surgeon Superintendent, Mayo Native Hospital, to come and see the case. Dr. SANDERS, accompanied by Dr. COOK, the Health Officer, came to see the patient at 7 A.M.

The patient was then quite comatose; his conjunctivæ were as before congested. He lay mostly on his right side, never on his back, and his face wore an expression of fear. His temperature had risen to 105°6' F. The pulse was weak, frequent, and small. The thumbs were flexed on the palms and both hands were turned inwards and were rigid. The gland was more painful and the skin covering it was red and warm. There was also a diffuse swelling round the gland.

He was able to open his mouth a little, but could not protrude his tongue. He was moaning. There were no marks of chancre on his penis, nor had he gonorrhœa. Drs. SANDERS and COOK pronounced the case as one of true plague, and at the suggestion of the former the patient was admitted in hospital in a room where he was kept quite isolated.

His feet soaked in perchloride of mercury lotion

(1 in 2,000) were hung at all times, and windows of the room. Ice was applied to the head and 5 grs. of calomel with 10 grs. of soda was put on his tongue at once. He was ordered to be sponged down every two hours with vinegar and tepid water to which a little of the perchloride lotion was added. The spitte from his mouth was mopped up with pieces of cloth dipped in the same lotion and burnt immediately after use. Nothing was applied to the painful gland.

At 2 P.M. the temperature was 105°4'. All the other symptoms continuing. As he could not swallow nutrient, stimulant, peptonised enemata were ordered every two hours.

He passed a stool in the bed clothes. The stool was disinfected with the mercury lotion. At 7 P.M. the temperature fell to 104°6'; the other symptoms remaining as before.

14th May 1898.—At 7 A.M. the temperature was 102° F. His pulse was feeble and frequent. He regained some consciousness, and looked up when spoken to, but could not speak. He could only protrude the tip of his tongue. The right eye was slightly clear, but the left continued, was still red from congestion. He had a slight cough. The gland was very tender.

At 8 P.M. the temperature was 101° F. The pulse, though not so frequent as before, was still very weak. He was more conscious and when asked to put out his tongue, he did so with difficulty and in a jerky way.

This was the first occasion on which the tongue was seen. It was dry and covered with a thick white coating fur, but its edges and tip were moist and of a red color. The teeth were covered with sordes. He was now able to swallow and lie on either side as well as on his back. His eyes were clearer. He was not moved. His mouth was swabbed with borax and glycerine and he was put on liquor hydrargyri perchloridi 3ss., liquor strychniæ B. P. miii, Aqua ad. ʒi t.d. To-day was for the first time he drank some milk. At 7 30 P.M. the temperature fell to 100°2' F. He was quite conscious but answered questions incoherently; his speech being thick, drawling and hesitating. He asked for tobacco.

15th May 1898.—The patient was improving. The temperature fell to 99° F. The tongue had a healthier appearance; there being only a thin coating of white fur here and there over its surface. His appetite was better. The bubo, though still painful, was larger in size than on the day of admission, but it showed no signs of fluctuation. The stupid look noticed at first had not yet disappeared. The hesitating speech also continued. The temperature remained 99° F. all day, but at 8 P.M. it rose to 101° F. preceded by a slight rigor. The patient looked dazed. There was muttering delirium and at times he sang. The pulse, which had improved, became weaker. A bromide draught had the desired effect of quieting him.

16th May 1898.—At 7 A.M. the temperature fell to 99°4' F., but rose to 102° F. at 3 P.M. The low muttering delirium continued; the tongue was moist and clear, and his eyes were clearing up. During the day he was alternately calm and boisterous. At 9 P.M. his pulse was very weak. The following mixture was given him:—

℞. Hydrargyri Perchloridi	...	ʒss.
Liq. Strychniæ	...	ʒi.
Aqua	...	ad ʒi t.d.

12th May 1898.—In the morning the temperature came down to 97°. The general condition of the patient had not however improved. He was alternately violent and calm, the low muttering delirium continued, and the breathing was easy. The bubo was smaller, though still very painful to the touch. He continued in this state all day. The temperature rose to 100° at 2 P. M. and 102° at 9 P. M. He did not however refuse food.

The bromide mixture was given every four hours, and the mercury mixture was discontinued.

13th May 1898.—The patient was better as regards most of the symptoms, though the pulse was in a very low state. He answered questions rationally, yet talked nonsense at times. He spoke slowly, drawing out his words. The bubo continued to be smaller, but there are no signs of fluctuation. He was given

Tr Strophanthi	mij
Liq Strychnine	mij
Aqua	3i t d.

And oleate of mercury ointment was applied to the bubo

At 3 P. M. there was a marked improvement. He was not delirious. The tongue was moist and clean. He had one stool after the glycerine enema, which had been given at noon that day. The temperature, which had risen to 99° F., fell to 98° at 9-30 P. M.

10th May 1898.—The patient continues to improve. The temperature was 98° in the morning, 100.6 at 3 P. M., and 99.2 at 9.30 P. M. There were no signs of fluctuation in the bubo.

20th May 1898.—Continued to improve. Speech is not so thick and less hesitating than before. Pulse has improved. The bubo is soft. There is no fever.

21st May.—Improvement continued. Bubo soft. No fever.

24th May.—Bubo more prominent and fluctuating. No fever.

Dr. SANDERS opened the bubo antiseptically, injecting the cavity with strong tincture of iodine. Sanious pus was received into a basin containing a little perchloride of mercury lotion. Strips of bandage cloth soaked in perchloride lotion were used to wipe the wound. The wound was dusted with iodoform and bandaged with a pad of mercurial gauze and absorbent cotton. All the dressings, &c., were put into the basin soaked with perchloride and were immediately burnt.

30th May.—The patient has made uninterrupted progress from the date of the last report. The temperature has been normal; his appetite has improved, and he is daily gaining strength. The bubo is daily dressed antiseptically and has now almost healed. He experiences no inconvenience in sitting or standing.

Remarks.—The stupid look of the patient, the intense injection of the conjunctiva, relapsing unconsciousness, the anuric of the thumbs and hands which were rigid, the painful nature of the glandular swelling in the right groin, which was of the size of a walnut with a diffuse swelling all round it, and the skin covering the gland being warm and of a red color, involuntary motions, the persistent vomiting, the cough and high fever all pointed to the case being one of true plague. There were no signs of any venereal disease. The diagnosis was confirmed with the progress of the case, and by the fact that when the

patient did put out his tongue, it was with a jerk, as in a jerky way and from the condition of the tongue already described. No symptoms of plague were observed among the hospital attendants who attended the plague case and all the other patients as well, and the people attending the out-door department of the Chandney Hospital and even among the in-patients. The disinfectants used and the precautions taken were such as could be employed in every case. These were the hanging of antiseptic screens, disinfection of the hands of the attendants before going into and after coming out of the room, and the burning of all articles of clothing and bedding and excreta of the patient. The cost is moderate that it is within the means of most, if not all, people. It may therefore be reasonably inferred that plague is neither infectious nor contagious, and that a person may be treated at his own house, provided there be a room in which he could be cared for as in the previous case.

PECULIAR DOUBLE STONE CASE. ONE STONE ENCYSTED IN UPPER AND ANTERIOR WALL OF BLADDER. SUCCESSFUL LITHOTRITY.

BY WM HUNTY, M. A., M. D., B. Sc.
Nussersabad.

THE patient was a Mahomedan, aged somewhere between fifty and sixty. His face bore the look of suffering, and his chief complaint was pain in one particular spot half an inch behind the glans penis. He believed, and had been told by many hakeems, that he had gonorrhoea and, so far as he could remember, the trouble had existed over five or six years.

On pressing the urethra at the spot indicated, the patient winced, and I passed a catheter with a view to find out if there was a stricture of any kind present. Finding no stricture, I went on to the bladder to see if any stone were present, and the catheter ran alongside a decidedly large one.

Guessing it at about three ounce weight, on consideration it was decided to crush and evacuate.

On the morning of the operation the patient was again persistent in his statement that the trouble was at the aforementioned spot and had nothing to do with stone. The stone which seemed to resemble in shape an egg, gave some trouble before it was caught in the lithotrite, and it was with difficulty that the blades grasped it, seeing that in one position the interval between the male and female blade was so wide as to preclude the locking of them.

When once broken the breaking of the fragments went on apace, but now and then I found the blades catching what I thought the half of the stone and repeatedly slipping off.

Evacuating the fragments I still had the same experience of the slipping, and also found that the supposed piece always seemed to fall to the right side of the bladder.

I realized that I might be dealing with a second and an encysted calculus, and so made careful and repeated attempts to dislodge. This failed and tracing with the point of the lithotrite I found that there existed an oval

stone in the right wall of the bladder. The stone, when passed up by the lithotrite, could be readily felt with the finger pressed a little to the right of the middle line of the abdomen and half way between the symphysis pubis and the umbilicus.

Thus there was a most unusual state of things to account for, a stone deeply encysted in the upper and anterior wall of the bladder, and the bladder evidently enlarged. The usual place for an encysted stone is at the lower and posterior aspect of the bladder, and it is an interesting question as to the origin of this encysted stone.

The probabilities are that the stone, which I crushed, and which weighed fully 2½ ounces, was first in the bladder. Violent straining or some other cause may have injured the wall and so a nidus for the deposit of layers of stone may have been prepared. Or what is more likely, a small nucleus has become embedded in an inflamed mucous membrane with the gradual formation of the mass in that position. I was not permitted to cut, through the special desire of the patient, and so had to forego the suprapubic operation.

FRACTURE OF LIMBS AND SKULL RECOVERY.

By RAN DHARI SINHA, L.T.M.S., M.I.M.A.

In medical charge, Civil Hospital, Abu Road

M, a girl *et. 6* years, was brought by her relatives to the Civil Hospital in an unconscious state on the 14th June 1894 at 12-15 (noon)

History related by her relatives—The girl, while running upstairs, fell from a height about 31 feet and received the following injuries (1) Simple fracture of lower extremity of left radius (*Colles'*); (2) dislocation of the left elbow joint (backward dislocation of ulna only), and (3) simple fracture of the skull at the superciliary ridge of the left frontal bone.

Condition on admission (half an hour after the accident).—She was totally insensible; her respirations were stertorous and sighing; pulse slow and labored, pupils were dilated and her spinal sense paralysed. There was ecchymosis on the subconjunctival and superciliary regions. She could not answer questions put to her. Temperature was subnormal.

Treatment—The injured limb was attended to. The patient was confined to bed and her head was well raised. I at once incised the ecchymosed spot at the superciliary ridge. About an ounce of thick, black (*coagulated*) blood was made to flow, whereby the girl began to rally, moved her limbs and head. Ice was freely applied to her head. The wound was antiseptically dressed and the fracture and dislocation treated appropriately. The following was injected hypodermically as she could not swallow anything.—

R. Quina Sulphat	gr. ij
Liq. Strychnia Hydrochlorat	℥iij
Ether Sulph.	℥v
Mist. Camphore	℥xxx

After an hour she began to cry but her voice was almost inaudible. The following mixture was ordered and continued till her recovery:—

R. Pot. Bromid	gr. v
Pot. Iodid	gr. ℥ij
Mist. Camphore (iced)	...	ad	gr. 3

Every three hours together with iced milk. The

swimming temperature rose to 100°F. Temperature improved, but she could not answer questions. Her special sense still dull and apathetic.

On the 15th June 1897, the morning temperature was 99.6°F., looked inerry, no stool nor urine was voided. The same mixture every three hours was continued with milk and sago. Ice to head and iced water as drink. Six leeches were applied on the ecchymosed left upper lid after which she could open the eye. Arnica lotion was instilled in the affected eye. There was motor improvement, but she was allowed to move.

On the 16th June 1897, temperature normal, no stool nor urination since the accident. An enema of castor oil was given with the result that she passed several small *scybala*; she passed urine after two hours with another voluntary stool (*catheter not used as her relatives objected*). The mixture and milk and sago diet continued, with ice on the head. She seemed better but could not speak; she turned her head to indicate "yes" or "no."

On the 17th June 1897, she was well and was playing with her brother and sisters. The defecation and urination became normal, but she was still dumb. The diet was changed for rice and milk. Her relatives requested to take her home, and I allowed them on the condition that she should attend the out door hospital for change of dressing. After five days of her discharge, she began to speak audibly. The wound healed by the first intention, and the fracture and dislocation were making rapid progress towards recovery.

Remarks.—The above case is interesting for the following reasons.—(1) That the wound received at the left superciliary ridge injured the posterior part of the inferior frontal convolutions and lower end of that of the ascending; hence aphasia for more than a week, (2) suppression of stools and urine for three days, due probably to the implication of inferior portion of the spinal nerves by *counts coup*, and (3) the immense value of the ice application in the surgery of head.

MAGNESIUM SULPHATE IN DYSENTERY,

By J. MORTON, M.D., L.R.C.P. & S. Edin.

Mussoorie.

A GREAT deal has been written of late on the treatment of dysentery, and especially by magnesium sulphate. A quotation in *The Lancet* proves that this drug was used nearly a century ago for a similar purpose. The credit, however, of reviving it must be given to Surgeon-Major LEAHY of the Indian Medical Service. Dr. WYAT-SMITH also may fairly lay a similar claim. This is academic and may be settled at some future time. I simply desire in this note to publish some cases of mine, as an encouragement to others to regard sulphate of magnesium as the remedy *par excellence* for acute dysentery. Last year and the year before epidemics of acute dysentery broke out among the pupils of St. Fidelis's Military Orphanage, of which I have medical charge, 41 cases were treated in 1895, and 35 cases in 1896, by a saturated solution of sulphate of magnesium in teaspoonful doses given every hour with very happy results. The stools lost their dysenteric character on an average in about 48 hours. The diet consisted principally of milk preparations, and especially

strawberry in milk, which I consider of great value. Previous to adopting this treatment, I had tried large doses of ipecac, then ipecac sine emetina, and a host of the older drugs with very disappointing and two fatal results. I noticed a slight tendency to diarrhoea after the magnesium treatment, but this rapidly subsided under the following mixture :—

R Acid Sulph. Aromat. . .	3i
Tinct. Gentian . . .	3iss
Inf. Gentian Co. ad . . .	3viii

Fiat mist.

Two tablespoonful (in adolescents) every three hours.

MORBID GROWTH OF CONJUNCTIVAL TISSUE. OPERATION ; RECOVERY.

By JAGGAMATHI, L.M.S.

Lahore.

A. B., an aged man of about sixty years, came to me some days ago for advice about a morbid growth of the conjunctival tissue with the tissue beneath in his left eye. The growth was of a peculiar shape, having nothing like that of ordinary pterygium though superficial like it but a little thicker with slightly injected vessels on its sides.

The removal of the above growth was considered advisable, and what I did was that I snipped the end of the growth which was on the cornea opposite the pupil, but as it bled much more than what was expected, I did not think it proper to do anything more than ligaturing the growth tightly near the attached end and then washing it with boracic lotion and tying up a tight bandage on the eye, asking the man to keep the pad under the bandage wet with the lotion and to come to me if there was any trouble. The man came to me two days after, the cornea from over which the growth was snipped was quite clear ; there was no bleeding and the growth had quite shrivelled. I cleaned the eye and asked the man to come four days after, which he did. The thin shrivelled growth had fallen off, the ligature was absent, and the only thing left was a trace of the growth on the place of its attachment.

HYSTERICAL VERSUS TRUE PERITONITIS.

There is given in this article a very good comparison between hysterical simulated peritonitis and true peritonitis. Simulation of acute diffused peritonitis by the hysteric is of rare occurrence, but in neuropathic women the localised inflammatory affections are sometimes very closely counterfeited. In hysterical peritonitis the pain usually predominates in the left side of the body. It often develops and ceases, like other hysterical symptoms, under the influence of moral impressions. In hysterical peritonitis a slight touch of the skin produces more distress than deep pressure, although in neuropathic patients deep pressure in the hypochondriac region causes intense suffering. In hysterical peritonitis there is often vomiting, but never nausea. The vomiting does not become fecal. The pulse and temperature in counterfeited peritonitis are usually about normal.

PLAGUE SERUMS.

PROPHYLACTIC AND CURATIVE.

As some misunderstanding appears to have arisen regarding the different plague serums mentioned from time to time in the press, it may be as well to clear up all doubt on the matter by giving a brief description of each of them and its object.

There are two distinct classes of serum ; one prophylactic or preventative, the other curative ; the former is used to prevent people getting the plague, the latter to cure them of the disease after it has been contracted.

PROPHYLACTIC SERUM.

There is only one prophylactic serum, that of Mons. W. M. HAFKINE ; the theory upon which its use is based and the method of its preparation were fully described in the issue of this journal for 16th December 1897, where also will be found an account of its successful employment in Daman, further particulars of its success at Uadhera, Taluka Baroda, will be found in this number.

CURATIVE SERUMS

There are three different curative serums, viz., Mons. HAFKINE'S, Mons. YERSIN'S, and Professor LUSTIG'S.

Treatment by means of these serums cannot be said to have had satisfactory results.

Mons. HAFKINE'S curative serum does not appear to have been more successful than the other two ; this want of success was freely acknowledged by him and published widely in the papers, with the result that many, not distinguishing between the curative and prophylactic serums, took this as a confessed failure of the latter.

Mons. HAFKINE, probably, seeing that no good results were likely to be gained by curative serums, did not pursue his investigations further in this direction, but confined his efforts to the perfecting of his prophylactic serum, which has been used on an unprecedented scale, and has given uniformly good results.

Khan Bahadur N. H. CHOKSY, in his "Report on Bubonic Plague," based on observations at Arthur Road, Bombay, alludes to these curative serums in the following terms :—

"Sero-therapy was tried on an extremely limited scale and the serums that were used were those of Professor W. M. HAFKINE, O.M.S., and of Dr. YERSIN ; also a serum prepared in Russia according to YERSIN'S method, and that of Professor LUSTIG of Florence ; both Professors HAFKINE'S and LUSTIG'S serums were what may be called experimental and by no means perfected, and both the professors, before giving them a trial, disclosed anything like finality or perfection, either in their mode of preparation or application. Fifteen cases in all were injected by Professor HAFKINE ; of these 9 were cured and 6 died ; 14 of these were acute cases, of which 6 died and 8 recovered. The other case was not making favorable progress, although fairly comfortable, and the serum was injected with a view to hasten his recovery,

and he recovered." The usual routine treatment was not stopped in these cases.

Yersin's serum, which was said to effect miraculous cures, was tried only in three very early cases, which alone Dr. YERSIN considered amenable to his serum. The mildest of them recovered after a very long and protracted convalescence, the two others dying within 24 hours of the injection."

"The Russian serum, prepared according to Dr. Yersin's method, was tried by Professor LEWIN of the Royal Military Academy of St. Petersburg, it failed to show any results even in a single case, as all the cases injected with it died."

Professor LUSTIG's serum was tried in six very serious cases during June and July, and the result of the treatment was exceedingly satisfactory. All the six cases so treated recovered. Even if it be assumed that the cases, though severe, were in the decline of the epidemic and therefore less virulent, still the cent. per cent. recovery rate is remarkable and shows distinctly that the serum had an extremely favorable influence. The usual routine treatment was followed in these cases."

Dr. YERSIN's curative serum was prepared in the same way as anti-diphtheritic serum, that is by immunising horses against plague by the injection of prepared cultivations of the plague bacillus, and then drawing off the serum from them.

In addition to horses Mons. HAFFKINE appears to have used a number of other animals.

In the treatment of plague cases by these serums, as we have said, no very definite results were obtained; one reason that is put forward to account for this is that the serums actually used were too weak.

The following are the conclusions expressed by the German Plague Commission on Dr. YERSIN's serum. —

The experiments made on monkeys with strong serum showed it to possess undoubted curative properties, though, of course, this can only be held to apply to the animals on which the experiments were made.

Whether a similar curative action can be attained in the case of man must not, as the observations made on the similarly sensitive grey monkeys show, be rashly concluded, but must be found out by observations on men sick of the plague. In such cases it seems that up to the present only the weaker sorts of serum have been used.

The Russian Commission also experimented on monkeys and made the following statements :—

"Our experiments in this direction conducted on 95 monkeys demonstrate :

(1). Yersin's serum can cure sick monkeys, when the treatment has been begun two days after the animals have been infected subcutaneously, and when the symptoms of plague have already shown themselves by elevation of temperature, buboes, etc.

(2). Serum treatment is not successful when begun too late, say 24 hours before death, in the monkeys used for control experiment.

(3). The quantity of serum necessary to cure monkeys is not very large; as a rule, it was sufficient to inject 20cc. of serum whose strength was equal to 16.

(4). If the quantity of serum injected is too small or if the treatment is begun too late, a cure may be obtained but sometimes the cure is only apparent and a relapse may occur which causes death in 15 to 17 days.

The members of the Russian Committee commented favorably on the Yersin treatment. They say:—"As regards the treatment of the sick by Yersin's serum, we must say that in several cases we have been able to observe interesting and striking effects, from its action. After the injection the temperature falls, drowsiness or delirium disappears, and the patient feels more comfortable. In general the results have not been as good as we could have wished, they have, however, reduced the mortality to 40 per cent. on those treated."

"Our experiences have, however, shown us that the serum has an undoubtedly good effect, the high death-rate is explained by the following causes :—

(1). The sick only come to the hospital four or five days after the beginning of the disease; this is very late.

(2). We cannot tell how long the patient has been ill; the intensity is not the same in each case. Some die in 24 hours; others live for 24 days.

(3). Men exhibit great variations in their susceptibility to infection. Monkeys are more uniform in this respect.

(4). In cases of pneumonic plague, the difficulty in obtaining a cure is often explained by the presence of other bacilli, pneumococcus and streptococcus.

(5). We hope to obtain better results with the antitoxin that Dr. ROUX has prepared, what has been used hitherto is more preventative than antitoxic.

(6). When a remedy has succeeded in saving even a few lives, it is enough to attract attention to it and to lend interest to its study. In reality Yersin's serum has saved a great number, and we must advocate his method of treatment very warmly. The serum is the only remedy known for plague up to the present time.

Dr. BITTER's opinion of YERSIN's serum is, however, unfavorable, he says :

In addition the specific treatment by the injection of YERSIN's anti-plague serum has not, as far as I know, given any conclusive results. On theoretical grounds it appears to me necessary to make the following remarks which demonstrate that the statistics of successful sero-therapy must be received with every caution :—

In the first place about 50 per cent. of all cases of plague (excluding pneumonic cases) recover naturally, they do not therefore require serum injections. In the cases which tend to run on to septicaemia, I think that the injection must be given at the onset of the disease, while the bacilli are still confined to the primary bubo, if there is to be a chance of preventing them from entering the blood. Once septicaemia is set up, there is, in my opinion, only an infinitesimal chance of avoiding a fatal termination, even though the strongest serums are used.

—o—o—o—

DR. BITTER ON THE PATHOLOGY OF PLAGUE.

IMPORTANT DIAGNOSTIC FEATURES OF THE DISEASE.

We are indebted to Dr. BITTER, of the Egyptian Plague Commission, for the clearest and best account of the pathology of plague from the bacteriological stand-point that we have come across. We give the following translation for the benefit of our readers :—

The plague, as we are aware, is one of the most multi-form diseases known; all the ancient authors, who have studied epidemics, insist upon this point.

I was surprised at the beginning of my observations to find how much the clinical symptoms varied, and what a striking there was in the pathological changes revealed at autopsy.

When we consider that in other epidemic diseases, as enteric fever, relapsing fever, small-pox, pneumonia, the cases are similar and almost invariably present the same clinical features, and that in others like cholera and diphtheria the symptoms vary within very narrow limits only, one would be inclined at the onset to look upon the different forms of plague as so many different diseases.

I will not enter into clinical and pathological details, beyond what is necessary to make plain my view of the nature of the disease.

In the first place it will be sufficient to state that all the symptoms, numerous and confused as they appear at first, can be referred to three sufficiently distinct forms of the disease, the difference between which is not artificial but follows logically from the different parts of the organism attacked by the bacillus, which, according to its distribution, produces different symptoms and pathological lesions.

Before entering into a detailed description of these three forms, in order to make myself clear, I must briefly explain the general idea I have arrived at, as the result of my observations, as to the nature of plague and of the bacillus which produces it.

In giving here the definite result of my studies, I hope to make more clear what I have to say about the pathology and symptoms of plague upon which my conclusions are founded.

The plague bacillus belongs to the class of septicæmic bacilli. These bacilli have the following characteristics—

When a susceptible animal is inoculated with a minute quantity of a cultivation of the microbe, the microbe begins to multiply immediately, and without producing any apparent local reaction it enters into the blood of the animal, where it finds the real field for its development, and where it multiplies freely until the whole vascular system is crowded with bacilli, and the animal dies.

This effect invariably results when the inoculated animal is susceptible in the highest degree.

For each kind of septicæmia there is one or more animals who possess this absolute susceptibility. There are others that are not susceptible; these can be inoculated with enormous quantities of septicæmic bacilli without effect. But between the predisposed and the refractory, there are usually found animals that possess all degrees of sensitiveness. As a rule, diminished susceptibility shows itself as follows: while the predisposed animal exhibits no local reaction after inoculation, the less susceptible animal, on the other hand, reacts by a more or less acute local inflammation. In this reaction we see an effort of the organism against the microbe. Sometimes the bacillus succeeds in entering into the blood and the animal dies. But in other cases the organism gets the upper hand of the microbe at the place of inoculation, it is destroyed in the inflamed tissues, which are themselves often subsequently destroyed by suppuration.

In reality, the phenomena that I have outlined are much more complicated. Just as different races possess a different degree of susceptibility, so amongst animals we find an

individual predisposition allied to an incomplete susceptibility. Further, the virulence of the inoculated bacillus, and the quantity of the microbes introduced into the system, exercise an important influence over the result of the inoculation. It would take too long to consider all these possible contingencies in detail, suffice it to say that each of them may have its influence on the course of the plague.

The best, and the best understood example of a septicæmia of this kind is anthrax. The smallest quantity of this specific bacillus introduced into a small wound in a mouse kills it with absolute certainty, without the least local reaction taking place. In rabbits there is often a local reaction, feeble it is true, and the animals sometimes survive. In cattle and horses the local reaction is well marked as an extensive redema which occurs around the seat of inoculation, but in spite of this a large number of animals still die of septicæmia.

In man the susceptibility to anthrax is still less. The local reaction occurs clearly and in a well-marked form as a malignant pustule or anthrax. In the majority of cases the individual escapes, but on the other hand a sufficiently large number of cases of anthrax are followed by fatal septicæmia. If the anthrax bacillus enters (with food, etc.) into the intestines of man, the result is an acute inflammation (enteritis) which is almost always followed by fatal septicæmia. In the same way if the spores enter the lungs, they give rise to pneumonia which is followed by septicæmia.

In plague we have a disease which has many points of resemblance to anthrax.

The smallest quantity of the virulent specific bacillus inoculated into rats or mice invariably kills them by septicæmia without any local reaction appearing. Man does not possess this highest degree of susceptibility to the plague bacillus, up to a certain point he is refractory.

Consequently, the entrance into his body of the bacillus, is always marked by a local reaction more or less intense, and it is only in a certain number of cases that the primary localisation of the bacillus is followed by septicæmia.

But there is one characteristic of plague, which distinguishes it from other known varieties of septicæmia, it is this, in general the local reaction caused by the invasion of the bacillus of plague does not occur at the place of inoculation, but in the lymphatic glands which correspond to this region.

This reaction shows itself chiefly in a painful swelling of the glands which is more or less pronounced; it is these inflamed glands which are called buboes, and which have long been considered as the most characteristic symptom of plague, and from which the name of bubonic plague has been derived.

As the onset of the disease the bacilli are exclusively confined to the glands, they multiply there, and in addition to the local alterations give rise to general symptoms more or less severe. In a certain number of cases the bacilli remain in the glands throughout the course of the disease; they neither penetrate into the surrounding tissues nor into the vascular system. The organism which struggles against them is unable to prevent their further multiplication and finally kills them at the seat of their first development.

in a small number of cases end by undergoing resolution, but in the majority their substance is changed into pus, cases of this kind are usually followed by cure.

In another class of case, the organism succumbs in its struggle with the bacillus. It is unable to limit it to the glands. The conquering microbe breaks through, so to speak, the filter which the organism opposes to it; it penetrates into the surrounding tissue and then into the blood where it multiplies freely. Then we have a septicæmia which is always fatal.

There is a third class of case, which is analogous to pulmonary anthrax. While in the cases already considered, the point of entrance of the microbe is a small wound, in this class it is the respiratory system. The bacillus is inhaled directly into the lungs, it settles there in one or more places and begins to multiply. The consequence is a strong local reaction which appears in the form of lobular pneumonia, more or less extensive. In these cases there are no buboes.

In cases of this kind the organism appears very rarely to overcome the bacillus. Such cases observed in Bombay were, with one exception, all fatal.

To recapitulate. We can distinguish between three different forms of plague —

1. The simple bubonic form, where the infection is confined to one or to a group of lymphatic glands. These cases usually end in recovery.

2. The septicæmic form, which is always fatal.

3. The pneumonic form.

Possibly yet other forms of plague exist, for example an intestinal form is mentioned by authors who have observed the plague in Hong Kong. But in Bombay, neither in the clinical observations nor in the post-mortem examinations, have I ever found any evidence of an infection of this kind.

The multitude of clinical symptoms and pathological lesions, which I have mentioned above are explained by the three forms of the disease which I have pointed out, and also in addition by the fact, that in the first and second forms there is not unfrequently a secondary infection by other micro-organisms, especially by pyogenic micrococci, which influences the clinical features of the disease.

THE MORAL ASPECTS OF MALTHUSIANISM.

THE performance of the marital act in a manner, which frustrates it of its legitimate purpose, is branded with the name of Onanism, because the first authentic instance of this kind is recorded of Onan. There is no uncertainty about the verdict of theologians regarding the use of the check-passary or any other means employed to prevent conception a practice deriving its name from the advocacy of the Rev. T. R. MALTUS—Malthusianism. Without waterlog upon their arguments, it is sufficient to state, here, that they condemn the application of any such means as intrinsically evil and not permissible under any circumstances. How far are theologians in this matter supported by the principles and deductions of natural ethics? Let us see.

No lengthy process of reasoning is required to arrive at the conclusion, that procreancy and implications are

not the proximate determinants of human actions, neither is it difficult to show, that pleasure and utility are not sufficient motives for the rational will. If they were, the thief, the drunkard, the adulterer would not be criminals, and the existence of law-courts would be anomalous. There is a natural law, deeply engraven in the human heart, by which every individual, capable of reasoning, is required to regulate and measure his conduct by those moral principles, which, being innate in man, form the basis of his practical judgment. The knowledge of the primary dictates of morality is common to all, but education is required to develop them. The less the mind has been trained in applying them, the more it is liable to go astray in drawing inferences from them, and, consequently, the more apt to get entangled in apparently contradictory postulates of morality. The dictum *errare humanum est* is as applicable to moral as to scientific conclusions, nay, there is greater danger to err in the former, because the fascination of evil and the allurement of self interest may easily intervene to thwart the understanding in judging of practical issues.

It is necessary to enter into some details regarding the primary principles of morality in relation to the passion for sexual intercourse, in order to determine the reasons, why the prevention of conception cannot be defended upon moral grounds; and if by these, practical Malthusianism stands condemned, the cause for its defence must yield the palm to superior and more urgent claims.

The inclination to sexual union is altogether natural, but is it in itself a sufficient determinant to actual intercourse? Reason says no, and even the most uncultivated savage will admit that its indulgence must be postponed to the proper time. But what is the purpose of these cravings of nature? Not, certainly, the pleasure of the individual, for when they are not restrained, they exercise, in a very short time, a baneful despotism over man's better instincts, divert them into unnatural ways of gratification, and become most copious sources of bodily diseases, mental disorders and of moral degradation. The propensity of the sexes towards mutual union is, therefore, to be determined neither by the momentary impulse of the passion, nor by the gratification to be derived from its indulgence, but must be dominated and regulated by reason. Reason declares that the inclination is indispensable to mankind, because by its stimulus the preservation of the species is provided for, but it also dictates that it should not be indulged, except by marital intercourse. We use the word marital, and not sexual, because outside of marriage, all nations concur in condemning its gratification and in upholding the necessity of keeping it under control. Nature itself has provided a check upon its own deterioration, by attaching to the stimulus of this passion a concomitant feeling of peculiar shame.

Propagation includes the duties of not only supplying what is necessary for the nutrition of the offspring, but also of directing and superintending its mental and moral development. These duties are so intimate and entail such heavy responsibility, that, without the stimulus of sexual passion, implanted by nature, most men would shrink the burden of propagating the species. But as the gratification of the passion is necessary and the duties entailed by propagation are continuous, the constant warn-

which is not only sanctioned, but actually encouraged, as an agreeable habit, by the abiding love of the married couple. Unfortunately this, unreasoning, sentimental situation is often mistaken for love and is responsible for so many unhappy marriages.

Women alone cannot ordinarily provide for all the wants of her offspring. Of all animals, the infant man is the most helpless and the most dependent upon others; and, in proportion to his life, he remains so the longest. His wants, moreover, are not only of a higher material order, but, belonging as they do to a moral and intellectual sphere, they are of a different kind from the wants of the brute creation. In those animals, where the female is sufficient to provide for its young, the male does not remain with the female after colition, as we see in dogs; but where the female cannot alone provide for the young, there the male remains with the female so long as is necessary for the wants of the progeny. For human propagation, nature ordains the permanent union of man and woman. This union must be unconditionally permanent, because without the stability of an enduring matrimonial contract, binding upon both parties, the good of the offspring would not be sufficiently provided for; and the good of the race requires that the union should be binding in all cases, because nature has respect to the whole species, and not to fortuitous conditions. Divorce is not sanctioned by nature. Promiscuity is condemnable, because it prevents the expansion of the race, by producing sterility and disease, and, at best, by allowing the existing members a precarious existence.

But what has all this to do with the question, whether the prevention of conception is or is not allowable upon moral considerations? Just this, to clear the ground for the admission of the following principles and deductions:

1. That the inclination towards sexual intercourse does not exist for personal satisfaction, but for the good of the race.
2. That the sexual organs having no other purpose than that of generating, the voluntary emission of the semen for any other purpose is against nature.
3. That the indulgence of the sexual passion is never permissible outside marriage.
4. Therefore, that in the marital state, the marriage act should be exercised in accordance with the conditions and purposes of nature.

The advocates of practical Malthusianism must found their reasons upon considerations of propensity and inclination, pleasure and utility. These, as we have seen, are not sufficient motives to determine human acts, if reason opposes the claims of morality.

In all that is said above, we have abundant grounds on which to rest our condemnation of Malthusian practices. To prevent conception by any means, except abstinence, frustrates the end of nature and prevents the multiplying of the human race; it destroys the dignity of woman in destroying the ideal of motherhood, and reduces her to an instrument of untutored and sensual passion; the artificial means, by which conception is prevented, fosters immorality in the unmarried, as it gives them facilities to gratify themselves, without any corresponding burdens; it

opens the door to debauchery, and is a constant source of domestic unhappiness. It is the inevitable effect of wrenching the woman from the bosom of home. What more is required to show the practicality of Malthusianism, if the means resorted to obstruct intercourse?

The reasons brought forward to justify the prevention of conception under certain conditions, is amply refuted by the axiom: "The end does not justify the means," and by this other: "It is not allowed to do evil, that good may come from it." Certainly, if the woman is delicate, the husband ought to restrain himself and spare her strength as much as possible, without, however, having recourse to ways and means, which nature abhors. The dangers of child-bearing are inherent in the matrimonial contract, just as the dangers of the battlefield are the prospective lot of the soldier. Society must go to pieces if every one be allowed to shirk the obligations of his condition and the dangers of his state in life.

We have not touched upon the stock argument in favor of Malthusianism, that it checks the overgrowth of population. It is curious to observe, that (we are quoting from BACON'S Medical Jurisprudence, 7th edition, page 227) "ARISTOTLE, in his work on Government, enjoins the exposure of children that are feeble and deformed, in order to prevent an excess of population. He adds, 'If this idea be repugnant to the character of the nation, fix at least the number of children in each family and if the parents transgress the law, let it be ordained, that the mother shall destroy the fruit of her body before it shall have received the principles of life and sensation.' The mild PLATO also justifies this practice. In his Republic, he directs that 'children born with any deformity shall be removed and concealed in some obscure retreat PLINY, the elder defends the right of parents to destroy their children, upon the grounds of its being necessary to preserve the increase of population within proper bounds.' These philosophers lived more than 2,000 years ago, and seeing that Christianity opposed a barrier to the crime of foeticide and infanticide, has the world gained or lost by the prohibition of checking the excess of population? The argument that the population must be kept within the proportion of food supply, it may safely be asserted, may be an excuse, but is never the motive of Osmiats. Osmiats indulge in their nefarious practices from selfish motives. Nature, under the direction of a benign Providence, knows how to meet the so-called danger of overgrowth of population. In America the complaint is loud and frequent, that "the obstetrician finds his vocation disappearing among the American women from the face of the earth." This is what Dr. WALTER LINDLEY says in the *New York Medical Journal* for August 1895, and he adds that, "had the Rev. T. R. MALTHUS lived in the United States to-day, he would never have argued about the danger of over-population, as he did in his interesting volume on 'The Principles of Population'". The check on population, so far from being a physical good, is an unmitigated evil, morally and socially.

...the profession of medicine is a highly responsible one, and the public interest requires that the highest standards of education and training should be maintained.

The Government, therefore, has the duty of seeing that the medical profession is kept up to the mark, and that the public interest is protected.

In no branch of knowledge have more enormous strides been made, and with knowledge comes power; the wonderful advances of sanitary science and preventive medicine have enlarged the sphere of the physician's influence; no longer is it limited to the interchange of confidence between doctor and patient, it is felt by the whole State; medicine in its widest sense has become a portion of State craft, and the health of the people a matter of national importance.

There are certain questions connected with medical education, which at present are seriously occupying the attention of thoughtful men in England, and the best and surest road to their satisfactory solution is being earnestly sought; these very questions which have been made a subject of special representation to the Government of India, by the Indian Medical Association, are of paramount importance to the future of medicine and for the future of the medical profession in India.

This appeal for reform derives its importance from two distinct causes: first, from the intrinsic value of the results which are certain to follow their inception, secondly, from its urgency.

The question of urgency arises from the fact that the longer these reforms are postponed, the more difficult will they be to carry out, at present the changes advocated can be made with facility, postpone them and the obstacles will increase from year to year.

The lines upon which reform is asked for are (1) A uniform standard of preliminary examination, (2) a uniform standard of education and professional examination, (3) the formation of a Council to exercise disciplinary powers similar to those of the General Medical Council of Great Britain. Further details will be found in the Report of the fifteenth meeting of the Council of the Indian Medical Association, given in our last issue.

For the carrying out of these reforms, we are much better situated in India than our professional brethren in the British Isles; in both countries it is clearly seen that legislation is necessary, and that no further advancement can be made without it, but the simple form of Government in India renders this course much more easy for us.

In England the task of getting a medical bill safely through the complications of the House of Commons and of overcoming the obstacles that may be offered to it is one of the very greatest difficulty, and may take years in its accomplishment.

Should our requests be deemed reasonable and expedient, the path is at once cleared for their early inauguration, and that they cannot be considered either unreasonable or impracticable. We adduce the fact that the reforms asked for are the very reforms which a longer experience and ripe judgment have shown to be necessary in England.

...the public interest requires that the highest standards of education and training should be maintained.

Standing before the public interest, there is the great question of vested interests. Vested interests. What good is it to have not been wrecked upon these implacable rocks, but we would remind those who urge difficulties that vested interests do not stand; still they have, not the contrary, an unfortunate habit of growing, and of, what is even worse, multiplying. Judging from the rate we are at present proceeding at, the vested interests of to-day will have doubled in size and number in half as many years.

To-day they are few and weak, to-morrow they will be many and strong.

Medical education in Great Britain is conducted on a system as nearly perfect as can be; but who can say what obstacles to progress the nineteen different Examining Boards and the innumerable medical schools, with all their ancient rights and vested interests have not been?

It is freely recognised to-day that the competition amongst these various Examining Boards is an evil influence, and one that the urgency of the time is intent upon getting rid of.

How much greater would the difficulty be, in addition to the nineteen Examining Boards every medical school granted its own diplomas? Yet this is the unhappy and degrading process which medical education is at present undergoing in India.

Let an end be made to this system once and for all before it has gone too far. Let the different schools by all means undertake the instruction of the student, but let the final examination be a general one of uniform standard, conducted either by the universities or by some special body appointed for the purpose. Further, let no student commence his medical studies until he has passed a standard qualifying examination.

Difficulties so far there are none, should it be found necessary or expedient to permit the schools, that at present grant diplomas, to continue doing so, but little harm would result; for they would find it necessary to educate up to the general standard, and if the general examination became popular and gave a higher status, it is obvious that the majority of students would prefer it and the diplomas of these local schools would in time die of inanition.

As for a preliminary standard it is urgently needed. A perusal of the prospectus of some of the present existing schools reveals only too plainly that they have a difficulty in getting their requisite number of students, and that many students are permitted to enter upon the study of medicine without any preliminary test at all.

Many students, even amongst those who have succeeded in passing the very low standard of preliminary required of them, have not the mental calibre to profit by their course of medical study and to carry away a sufficient load of medical lore to elevate them into learned and useful men.

Is the science of medicine to be degraded in this way—a science which calls for the highest intellectual development, and where secrets are daily being sought after and unfolded by the keenest and most brilliant minds?

To elevate the standard simply means to get better men. It would appear indeed, from the present outlook of the question in India, as if the Government

looked upon a raised standard as synonymous with an increased expenditure.

Surely there is a future before Indian medicine, who can contemplate the vast extent of the country with its teeming population, millions of whom are out of the reach of skilled medical aid, whose births and deaths are unregistered, who suffer and die, and no man knows of what.

There must be a future also for scientific research, for the investigation of diseases, the elucidation of their etiology and the study of their therapeutics. Who is in the future to explore and make clear the vast and almost untrodden wilds of Indian pathology?

Surely a great portion of these noble and immense tasks must fall to those whose birth right is in the country!

True the native population of India is poor, but is this always to be the case; is there to be no improvement in this direction, and is this to be the final result of centuries of enlightened government? We refused to believe it; we have faith in the future of indigenous medicine, and we cannot refrain from noticing the vast strides that have been made in Japan under an active and go-ahead Government, in all matters of modern science.

We need add nothing more on this subject, save to say that we believe that the native princes and wealthy native gentlemen, if left perfectly free and unhampered, will take a large share in the progress of European methods of medicine in India.

It is only for the Government to pave the way, which will lead to the production of the proper material.

We have commented on some anomalies in the system of university education, and it may be said that as the universities are independent bodies, the Government can have no power to deal with them.

Now with regard to one point we touched upon, namely, the appointment of their professors; it is only too evident the universities have no independence whatever. They are entirely in the hands of the Government. Has any university the power to appoint a civilian professor of any branch of medicine or surgery, without any reference to the ruling body of the State, and yet for educational purposes what can be more important than that the teachers should be men carefully selected from the open field of competition, and that he should hold his "chair" as long as he can perform its duties in a satisfactory manner. The soldier surgeon, who is constantly being called away to active service, or moved to exercise his functions in some other sphere, is not the proper person for a professorial chair. In all cases when it is given to him he should be seconded for a certain number of years, as is done in every other branch of the service; but the rule for the university should be the best man apart from all other considerations.

As for the small point of unifying the standard of education and nomenclature, so that all the universities should have the same standard of examination and education and grant the same diplomas and degrees, the universities may be trusted to see to their own interests in this matter. Should the Government once show itself in earnest in the matter of putting its own schools in order, and suppressing the mushroom growth of hybrid imitations of the university titles, the universities will be only too ready to take their cue.

Ce n'est que le premier pas qui compte, let the Government but show itself in earnest and take the first step on the lines just indicated, and everything else will follow, like the parts of a machine when the fly wheel is set in motion.

As for the vaidas and hakims who at present to a large extent hold the field, let them alone for the present. Time will deal with them; in the present unsatisfactory state of our system they perhaps play a useful part, but when our house is set in order, and when the impetus that Indian medicine is at present feeling has gained a full power, and exercises a daily growing influence, vaidas and hakims will gradually sink into oblivion and be reckoned amongst the curiosities of the past.

COMMENTS AND NEWS.

THE CALCUTTA HEALTH OFFICER AND HIS DUTIES. A SERIOUS QUESTION.

THE following protest by the Indian Medical Association was submitted in its communication to the Bengal Government on the 14th May :-

"That the Health Officer be not permitted to employ his time in any other way except in fulfilling those duties which are strictly involved in the true sanitary interests of the town."

When the above protest was published in the daily papers, the *Englishman* thought fit to remark that this particular protest concerning the Health Officer "was not called for," and our contemporary even went the length of saying it was "impertinent." Subsequent events prove how necessary and just the protest was and how important it is in the best interests of the public in general and of Calcutta sanitation in particular that the above protest should not only be emphasised, but that it should form the subject of very serious consideration in the present hygienic crisis of the metropolis by not only the public themselves but by the Municipal Commissioners and the Bengal Government, who are responsible for this highly unsatisfactory and calamitous state of affairs.

To give point to the contention of the Council of the Indian Medical Association, we quote from the *Englishman* :-—"Dr. COOK's time was fully occupied on Saturday, the 21st May, in operating on about 250 members of Mahomedan families in Kumarabagan Lane. All these people volunteered themselves to be inoculated, and this is the largest number of operations that Dr. COOK has performed in one day since the commencement of the plague. Dr. (Miss) CHRISTIE operated on all the zenana women. Two hundred more Mahomedans of the same locality have offered to be operated on. The family priest of the Sovabazar family, Pandit Issua CHUNDER VIDYARATNA, was inoculated yesterday, with 15 others. Up to date 753 persons have been inoculated." This sort of news appears daily in the newspapers, and the question naturally arises, who is responsible for the sanitary work of Calcutta if its Health Officer is all day and every day inoculating for plague. Either Calcutta requires a whole-time Health Officer or a whole-time inoculator. Which of these is Dr. COOK? If inoculator, then who is Health Officer? We leave the Municipality to answer this question.

The following correspondence between Mr. R. T. GREEN, C.S., the Chairman, and Dr. J. N. COOK, the Health Officer, affords abundant justification to the above protest :-

"HEALTH OFFICER.

"Driving over the town to-day I noticed a large number of nuisances. The Nuisance Department might be stirred up."

30-5-98.

"CHAIRMAN.

"I have referred the matter to the Engineer."

30-5-98.

(Sd.) R. T. G.

(Sd.) J. N. C.

"The Health Officer, not the Engineer, is the officer responsible for reporting nuisances. I want the attention of the Health Officer to this branch of his duties."

1-6-98.

"CHAIRMAN.

"I should be obliged if you would inform me what my Nuisance Department consists of. Hitherto the conservancy staff has attended to nuisances, and I have not been informed of any alteration in this respect. Since the conservancy was transferred, I have had no inspectors of Nuisances and was

(Sd.) R. T. G.

not aware that I was responsible for reporting and dealing with nuisances.

(Ed.) J. N. C.

Does this not clearly prove that sanitary matters in Calcutta are in a state of utter confusion, and that however much such a condition of affairs might be condemned under ordinary circumstances, their existence at a time when the city is threatened with a most disastrous epidemic visitation—as officially declared,—it would be a most flagrant dereliction of public duty, for the press, more especially the medical press, to be silent when its voice should be heard in the most emphatic denunciation of those in authority upon whom such grave responsibility rests.

THE DANGER OF ASPIRATING THE LIVER.

SURGEON-COLONEL W. F. STEVENSON, A. M. S., Professor of Surgery, Army Medical School, writes to *The Lancet* as follows:—"Surgeon-Lieutenant-Colonel HATCH, I. M. S., has done well in drawing attention in the *Indian Medical Gazette* for April 1898, to the possibility of aspiration of the liver producing a fatal hemorrhage into the cavity of the peritoneum. This important fact is but little known and has been seldom referred to in writings on the treatment of liver abscess. Surgeon-Lieutenant-Colonel HATCH recommends caution in the operation of aspiration of the liver for diagnosis of abscess, but you go further and state that 'the operation offers no advantages to compensate for its undoubted risk' and recommend its total disuse. This view will not, I believe, commend itself to the majority of surgeons and, if adopted, will result in patients dying from liver abscess unrelieved because their condition remains undiagnosed. The advantages of the operation are the certainty of diagnosis as to the presence of an abscess and its position if a positive result be obtained, and its almost certain absence if pus be not reached on the insertion of the needle at three or four situations. The books notwithstanding, there are no symptoms or physical signs on which the surgeon can depend for indicating the necessity of operation in cases of suspected abscess of the liver; perhaps of the latter the lems of the skin is the most valuable, but it is very seldom apparent, not oftener than in 4 or 5 per cent. of the cases—a sense of fluctuation may be left out of consideration, as it is hardly ever perceptible. I have discovered by means of aspiration liver abscess in cases where the classical symptoms of this complaint were all absent and where only pain over the liver and the patient's history warranted a bare suspicion of its presence, and I have found it on post-mortem examination in cases which during life exhibited no sign of it. Probably no disease presents cases in which diagnosis is more difficult than it is in some cases of liver abscess, and in these 'prospecting' the organ with an aspirator affords the only certain data on which to form an opinion. I have treated a large number of cases (over 150) in which abscess of the liver was present or suspected, and my routine plan has been to aspirate first at one or more points and then to operate on a positive result being obtained. In those cases in which pus was not reached no evil effect was ever perceived, the only result being a very considerable decrease of the pain previously felt, and this whether the amount of blood removed was great or small. The needle employed should no doubt be small, and that it be too narrow to permit the pus to flow freely, through it in some cases is hardly an objection, because even under these circumstances sufficient for merely diagnostic purposes may be obtained on expelling the needle from the india-rubber tube and blowing the contents on to the palm of the hand.

"In the face of the cases related by Surgeon-Lieutenant-Colonel HATCH and of others one must admit a certain amount

of risk from aspiration of the liver, but the ratio of fatal cases to the total number treated is almost infinitesimal and should be disregarded. The fact that *The Lancet* is read all over the world by medical officers who are likely to have these cases to treat must be my excuse for asking you to give space to this letter."

MONS. W. M. HAFKINE'S PLAGUE PROPHYLACTIC IN TALUKA BARODA. SUCCESSFUL RESULTS.

We are indebted to the courtesy of Mons. W. M. HAFKINE for a report on the effect of protective inoculation in the epidemic of plague at Uadhwa, Taluka Baroda.

The inoculations were performed at Uadhwa on the 13th February 1898, in which place the plague continued up to the 26th March 1898, i.e., for 43 days after the inoculations.

On the day of inoculation the population of the village was 950; 47 of these had been inoculated before, between the 26th January and the 2nd February and were not done again; of the remainder 466 were inoculated and 487 remained uninoculated.

To make the experiment as searching and the results as conclusive as possible, the inoculations were carried out as follows: in each household, as nearly as possible, half the number of the male members, half the number of the females, and half the number of the children were inoculated.

The following is a summary of results:—

Amongst the 487 uninoculated from the 13th February to the close of the epidemic, 26th March, there were 27 attacks of plague with 26 deaths.

Amongst the total number inoculated 466 plus 47 equal to 513 there were only 8 attacks and 3 deaths.

Plague broke out in 28 families, in these 28 families there were 64 persons uninoculated and 71 inoculated.

The 64 uninoculated members had 27 attacks of which 26 were fatal. The 71 inoculated had 8 attacks, of which 3 were fatal.

If the inoculated had suffered to the same extent as their uninoculated relatives, they would have had 29 deaths from plague instead of only 3, this is a reduction of 26 or 89.6 per cent.

This result, it must be remarked, tallies in a remarkable manner with all the observations made up to now upon the protective effect of the plague prophylactic, the reduction of mortality effected by it averaging, as a rule, between 80 and 90 per cent.

Attached to the report before us are 28 sheets giving full details of the composition of each affected family and of the incidence of plague in each.

These results were all investigated and confirmed on the 4th April 1898 by Surgeon-Major General R. HARVEY, Acting Director-General, Indian Medical Service, Mons. W. M. HAFKINE, Surgeon-Major BANERMAN, M. Rao Bahadur V. M. SAMANTH, Rao Bahadur NILKANTHA K. AMBEGAS-KAR, Rao Sahab RAMLAL H. DESAI, B.A., LL.B., Vakiladar of Baroda Taluka, and Dr. CHAGANPRASAD D. DIVANJEE, L.M. & S.

They require no further comment on our part, as they speak for themselves in no uncertain way.

COMMENTS ON LORD LANSDOWNE'S SPEECH ON THE A.M.S.

SAYS the *British Medical Journal*:—"We have received a number of press comments of a favorable character on Lord LANSDOWNE'S announcements concerning the Army Medical Service.

"The *Army and Navy Gazette* asks:—'What's in a name?' and answers, 'That depends on the circumstances of the case to which the question refers. Lord LANSDOWNE has acceded

to the wishes of the army doctors and through their influence, said if that in any way conduces to their happiness, social and military position, and professional ambition, as summonable man—soldier, or surgeon, or civilian—was object to the organisation. It will be a source of immense satisfaction if the best men now come forward from the schools to join the new corps.'

"The *Broad Arrow* says:—'The medical profession may fairly congratulate itself on having gained a complete victory, and routed the War Office with all its traditions and distinctions between combatants and non-combatants. The army generally will be only too pleased to accept the alteration, shadowy as it is rather than substantial. We may hope, if we do not quite believe, that we have now heard the last of army medical troubles.'

"The *Freeman's Journal* says:—'There has been a long-continued conflict between the medical profession and the military authorities.....At last the army authorities found the game of defiance played out....The profession has won.'

"The *Pall Mall Gazette* says:—'The 'Royal Army Medical Corps' is to-day congratulated on the success which has attended the justifiable and well-managed agitation of its members; not less is Lord LANSDOWN to be congratulated upon having overcome certain old-fashioned prejudices and upon the accomplishment of an act of justice that will do much to promote good fellowship between the combatant officers and their medical comrades.'

"The *Naval and Military Record* says:—'The recognition of the combatant titles of the doctors is now to be carried to its logical conclusion. Thus on all important issue the War Office has given way.'

REWARDS FOR PLAGUE WORK.

ATTENTION is drawn by a contemporary to the great disparity in the rewards given by the Indian and other Governments for work in connection with plague. The comparison, we need hardly say, is not favorable to the Indian Government.

The Indian Government is prodigal of graceful phrases of recognition. But for rewards of any substantial value we have still to look to the future with whatever hope we may.

In vivid contrast to this is the prompt action of the German Government. We learn that Dr. GAFFKY and Dr. PFIEFFER have received an honorarium of 15,000 marks each, and Dr. STRICKER and Dr. DIEUDONNE 9,000 marks each.

The two first-named doctors receive in addition the order of the Red Eagle of the 2nd class, and the others the same order of the 3rd class.

These rewards have been given for about three months' plague work.

When we think of the long list of rewards and honors so freely, not to say promiscuously, given for a few months' service on the frontier, the meanness of the thanks so stingily doled out to those who have borne the brunt of the prolonged and trying plague campaign appears to us to be far from reflecting credit upon a Government which is supposed to be civilised.

In its actions we have at any rate no difficulty in tracing the primitive ideas handed down from barbarous days, when war was held to be the noblest field in which man could display his powers and gifts. The march of civilisation does not appear to have as yet changed the attitude of the British or Indian Governments in this respect.

LIGHTNING-STROKE IN A PATIENT.

A curious case of injury due to lightning is reported in the *Prager medicinische Wochenschrift* for 10th February 1900, by Dr. EDWARD WARTZ. The patient had been injured by lightning two years before his admission, and, according to his story, he was struck completely unconscious for three days, after which he gradually regained his powers, but never perfectly. He was completely paralysed for nearly three weeks, and even then required two months more to regain any power in walking. His hearing was also very defective in the left ear, though perfectly good previously. The whole anterior surface of the body and the inner surface of the left thigh and leg were deeply burned. Since the accident the patient had been able to do light work, but was compelled to stop work every month or so because of severe pain in his whole body and excessive weariness, which became more marked on any change of weather. At the time of his admission he was a moderately well-nourished man with no evident disease of the viscera. Over part of the anterior portion of the body the skin was perfectly white, with well-marked elevations like those seen on the skin of a plucked bird and with but a very few fine hairs. Below, on the inner surface of the thigh and leg, were broad parchment-like stripes, the remnants of the old burns. Nothing else could be found, except an increased knee-jerk, some ataxia of the lower extremities, and a rather weak hand grip. The hearing in the left ear was still very defective. As is well known, says the author, the effects of lightning are very various, at times simply destructive, without any great amount of heat generation. The case illustrates very well this combined action in the shock to the brain and the burns on the body, and an additional evidence is the partial melting of a colic carried by the patient. The other symptoms of the case seem to have been very probably functional, since they were much improved by hydrotherapeutic measures.

TREATMENT OF PELVIC SUPPURATION BY INCISION OF THE POSTERIOR CUL-DE-SAC.

M. MONOD in the *Société de Chirurgie* writes:—'I have employed the method of opening the posterior vaginal cul-de-sac on forty occasions. I do not desire to invite attention to those cases in which this proceeding is adopted to evacuate a collection that presents in the vagina; but rather to those cases where it is necessary to penetrate deeply to open an abscess that is situated high up, and when there exists at the same time a suppurative perisalpingitis and an ovarian suppuration or salpingitis, forming a second sac contained in the first and at such a distance from the vagina that there is a danger of its being overlooked and being left intact, if the operator merely opens the posterior vaginal cul-de-sac.'

'I have observed this condition 23 times in double salpingitis and perisalpingitis.'

'In four cases the contents of the peri-salpingitic sac, opened by incision of the posterior cul-de-sac, were serous, while higher up there was an abscess. In seventeen cases, which resulted in sixteen cures and one death, the suppuration was unilateral with two abscesses, and in the four other cases, of which two were cured and two died, the suppuration was bi-lateral.'

M. BOUTIER said:—'I have frequently observed the phenomena described by M. MONOD, when after the opening of a sac containing either serous or purulent matter, a second sac is found containing pus. On account of the possibility of multiple collections, incision through the posterior cul-de-sac should always be followed by careful exploration by the bi-manual method, so that these collections may not be overlooked.'

MR. GLADSTONE'S DEATH. THE PASSING OF A GREAT MAN.

SAYS THE LANCET:—"We do not intend to give any detailed obituary notice of the great man who has just passed from among us. Our readers have before them the ample story of Mr. GLADSTONE's grand career in all the daily papers and in most cases it will be the province of such papers to discuss political matters upon which we are unable as a medical journal to take a view. But at the same time we desire to register our feelings of profound admiration for the dead statesman's lofty ideals, unrivalled intellectual powers, and wonderfully sweet and buoyant temperament. In Mr. GLADSTONE a lowly trust in God was joined to the highest aspirations for the good of humanity, and the sense of the loss which the nation feels itself to have sustained by his death cannot be adequately expressed. Medicine, its science and practice, falls as a part of the social scheme beneath the domination of a real national leader, so that in common with the rest of the community we rejoice when our leader is a good man as well as a great one, and while rejoicing benefit. It is unnecessary to point to special acts or speeches that we may prove Mr. GLADSTONE to have been the friend of those who follow our calling, though to do so would be easy. Being the man that he was it was inevitable that he should sympathise with us and with all who work to help the weak. For Mr. GLADSTONE was exactly 'the man of mercy' whom the Son of SIRACH has described, as he was and is, also, one 'whose glory shall not be blotted out' but 'whose name liveth to all generations.'"

The President of the General Medical Council said a suggestion had been made to him that the Council should join other public bodies in recording their sense of the loss which had befallen the nation through the death of Mr. GLADSTONE. He therefore moved the following resolution which was carried unanimously by the Council in Session:—

"That this Council desires to place on record its sense of the grievous loss which has befallen the nation by the death of the Right Hon. W. E. GLADSTONE, whose interest in the profession of medicine was ever warm and sympathetic, and under whose administration the Medical Act of 1896 was passed into law. The Council further requests the President to transmit to the widow and family of the deceased statesman a suitable expression of the Council's heartfelt participation in the national sorrow."

ABSCESSES OF THE LIVER.

THE two following cases of liver abscess treated by free incision are related by M. RICHELOT:—

The first case was that of a young man aged 23 years, who had returned from a two years' residence in Saigon and Tonkin, where he had suffered from dysentery. The disease had been diagnosed as pulmonary tuberculosis with localised empyema. M. LAFONCADA (of Bagoune, under whose treatment he came) diagnosed liver abscess following dysentery, and according to LAMBELOUGU's method resected the lower margin of thorax, which enabled him to freely incise the liver abscess. The patient died on the 32nd day.

In the second case, M. LAFONCADA opened the abscess by transpleural laparotomy, recovery followed without incident.

M. RICHELOT related a case of his own, in a man who had returned to France 10 years previously after having served in the Tonkin Campaign, in the intervening time he had only suffered from occasional attacks of fever, the liver extended to a considerable distance below the arch of the ribs, and in this situation laparotomy was performed and about 550 grammes of pus evacuated from a liver abscess. Three months later he incised a second abscess which presented below the xiphoid cartilage, and shortly afterwards a third abscess appearing,

it was also opened. Complete cure followed. The pus from the third abscess was sterile, that from the other two was not tested.

A DEBT COLLECTOR ON THE SYMPTOMS OF PLAGUE.

A GENTLEMAN, who signs himself ALAN J. AGABO, Superintendent, Public Debt Office, Bank of Bombay, in a letter to the *Englishman* under the above heading, is kind enough to treat us to some very original views of his own as to the true nature and pathology of plague; the ideas will no doubt interest as well as afford considerable amusement to our readers. "This so-called plague," we are told, is nothing else but a most virulent attack of "malaria," and the bacillus which has been discovered is no other than the "bacillus malarie" which has not been known in India before. It is something to be thankful for that the dreadful "bacillus malarie" has not previously visited our shores, but whence all the malarial fevers with which we are so well acquainted!

"The microbe," we are informed, "appears to be a vegetable of a group Schizomycetes, and of a family near Algae, it is so small that it is difficult to imagine its size."

Mr. AGABO appears to be an individual of the group meddlers, of a family near muddles, but his errors are so enormous that it is difficult to imagine their size.

Regarding symptoms he says:—"The skin only in very exceptional cases has shown black patches, and normally can you find the whole body blackened." The meaning of this charming sample of English "as she is writ" in Hindustani we leave to the discernment of our readers, while we wonder at finding it admitted to the columns of the *Englishman*.

PROFESSIONAL SECRETS.

THE *Medical Times and Hospital Gazette* says:—"The question of professional secrecy is one which perpetually recurs in very different forms. There can be no doubt of the absolute necessity for inviolable secrecy as to matters made known to a doctor by a patient in the course of consultation. One cannot, of course, severely blame a doctor who deviates from his plain duty in this respect owing to fear of threats by those who administer the law; but at the same time we must admire those who decline at all risks to betray confidence reposed in them. To do as some suggest ought to be done, namely to give information to the police of every crime (or what the law calls crime), which comes under medical notice professionally, would be as wrong in principle, as it would be ruinous in practice. There are, however, cases in which secrecy would be sure to endanger either the patient or others, and here the doctor must, of course, undertake the responsibility attached of necessity to the information acquired. If a patient betrays to a doctor plain symptoms of homicidal or suicidal tendencies, it is an obvious duty to take suitable steps to guard against consequences, and no blame can be attached to a doctor who finds it desirable to convey the information to those who ought to have it. Again, if a patient is dangerously infective, a doctor, in the event of the patient refusing to take proper precaution for the safety of others, might under some circumstances be justified in warning those exposed to risk. The exceptions, however, should be very few. The fixed rule is absolute secrecy!"

ANTIRABIC INOCULATIONS.

SAYS the *British Medical Journal*:—"The *Annales de l'Institut Pasteur* contains a brief summary of the work for the year 1897. The number of 'bitons' bitten by rabid animals and treated at the Institute was 1,861, and of these 8 died. If 2, cases in which death occurred before treatment could take effect are excluded, the 4 deaths give a total mortality of 0.80 per cent. The cases are classified under three

black; 2. Those bitten by dogs proved by injection experiments to have been rabid. 3. Cases bitten by animals certified as mad by veterinary surgeons. 4. Cases in which the rabies is suspected only. The mortality in the first of these classes is always higher than in the other two. It never, however, exceeds 1 per cent., and during the year in question only reached 0.7 per cent. Bites on the face and head were most fatal, the hands and limbs coming next in order of danger. Of the fatal cases one died six months after treatment, most of the others at intervals of a few weeks only. It is interesting to note that in 3 of the fatal cases the rabid dogs which inflicted the wounds were known to have bitten other persons who have not subsequently developed any symptoms of rabies. One of these persons had undergone a course of treatment at the Institute, the other had not. Of the 1,531 persons treated in Paris 175 were foreigners; the countries contributing the greatest number being—England, 33; India, 23; and Switzerland, 22.

LAND AND FLOATING HOSPITALS AT RANGOON.

ARRANGEMENTS have been made by the Rangoon Municipality to procure a loan of a river flat from the Irrawaddy Flotilla Company. This flat will be properly fitted up to meet the requirements of a hospital, and will be anchored in the river. The lower deck of the flat is being lime-washed from stem to stern, while the upper one will be similarly treated. The top portion has been matted in and equipped with other necessary arrangements. Lying alongside this flat is another but smaller flat-bottomed boat, which will be utilized as a disinfecting apparatus. To answer this purpose it has been equipped at one end with a machine and large boiler for generating steam, which will escape through a number of pipes into three reservoirs specially fitted up for facilitating the work of disinfection. At the opposite end two cabs have been built, into which a pair of trolleys will be run from the reservoirs with the infected linen, which will undergo a further process of disinfection under steam in an enclosed cell. The work of completion is being rapidly pushed.

It has been decided to erect a portion of the new General Hospital for Rangoon in order to provide sufficient accommodation for European and paying patients, to alter the present hospital, to build an infectious diseases hospital for Europeans, and to convert the present infectious diseases wards into wards for females suffering from contagious diseases, at a total cost of four lakhs, excluding the cost of the site for the new buildings. The Provincial and Fort revenues pay one-fifth, and the Rangoon Municipality four-fifths of the expenditure of three lakhs and fifty thousand on the contagious diseases hospital under consideration, but the Municipal Committee thinks that if the present vaccination law is amended by making adult vaccination and re-vaccination compulsory, this expenditure will be necessary.

The steamer *Thibis* is being fitted up in the Rangoon river as a hospital, while on the bank will be a segregation camp. The steamer will serve as a hospital for the whole town. A hospital will also be built at Thibabyu, where the present infectious diseases hospital is. This will be for the Eastern half of the town, and, if necessary, there will be a segregation camp on the newly-reclaimed ground. A meeting of the medical men in town will be held shortly to discuss matters. Two trained nurses have been sent for from England.

ENTERIC FEVER AMONG THE TROOPS IN INDIA.

SAYS THE *Times*.—General RUSSELL asked the Secretary of State for India whether the Government of India had arrived at any conclusion regarding the cause of the great decrease in enteric fever among European troops in India;

whether the investigations which it was proposed should be made were extended; and whether it was proposed to adopt any special measures to arrest the spread of this disease. Lord GOSWICK HAMILTON replied: No definite conclusion has been arrived at as to the cause of the increase in enteric fever among British troops in India, and the investigations on this subject are still proceeding, selected medical officers having been specially detailed for this duty. Generally the measures taken to check the spread of the disease are the improvement of the water-supply, the provision of pure milk and butter, and improved sanitation of camp encampments and barracks. One encampment, Draghah, where there have been serious outbreaks of enteric fever, has been completely evacuated for a year, pending the installation of an improved water-supply and the disinfection of the barracks and their vicinity."

SURGEON-CAPTAIN O. DALTON, A. M. S.

ANOTHER case of distinguished heroism, says the *British Medical Journal*, is thus alluded to in the *Army and Navy Gazette* of 7th May.—

"When Lieutenant CRAIG-BROWN, 1st Battalion, West India Regiment, was severely wounded in the fighting recently in Lagos, Surgeon-Captain O. DALTON, A. M. S., dressed his wounds on the spot where he was shot down amidst a hail of fire. A carrier, who was by his side at the time, was shot dead. Another thrilling act was performed by the same officer together with Sargeant-Major M'KILLOP. It was found, when the company got into safe quarters, that a wounded West India native had been left behind. The man was badly wounded. Captain DALTON and M'KILLOP at once went back, a distance of 500 yards, into the enemy's quarters under fire, and brought the poor fellow back. Unfortunately the man, whose name was BARNETT, died. The act was none the less one of great gallantry, and, as a correspondent puts it, 'at time when some would try to make out that the army doctor is simply a civilian hanger-on to the army, it is right that all honorable men among combatant officers should rise in revolt against such a libel and injustice, which can in the long run only produce its proper result.'"

THE GENERAL HOSPITAL AND DR. PILGRIM.

SURGEON-CAPTAIN HERBERT WILSON PILGRIM, I. M. S., is M.R.C.S. Eng., L.S.A. Lond. (1884), and M.B. Lond., (1885). He hails from the West Indies, and was medically educated in the University of Edinburgh and in University College, London. He joined the Indian Medical Service in 1886, and has therefore 13 years' service. He was appointed junior Resident Surgeon of the Presidency General Hospital in June 1890, and was promoted to First Resident Surgeon on the 1st of April 1891 on a salary of Rs. 900 per mensem. His present position, as Superintendent of the hospital, just doubles his salary. There is not another officer in the Indian Medical Service of his rank who is in receipt of a salary of Rs. 1,800 per mensem. Dr. PILGRIM has had 8 years' practical experience of the working of the Calcutta General Hospital, and if merit and special experience are to be accorded their just reward, Dr. PILGRIM certainly deserves his promotion. There can be no question of a doubt however that from a service point of view, the selection of a junior surgeon for so important an administrative office, will evoke the severest criticism, as in making such a selection the Government has over-ridden the established rules and regulations of the service.

TREATMENT OF ENTERIC FEVER BY THE INTRAMUSCULAR INJECTION OF BACTERIA.—SURGEON-CAPTAIN F. J. W. GOSWICK, A. M. S. (India) writes to the *British Medical Journal*—

the greatest credit is due to Surgeon-Major LAMKIN for bringing this method of the treatment of syphilis to the notice of the profession. It has been adopted by very many medical officers in this country, and with the greatest benefit to the soldier and the State. The reasons why it is not more extensively used are (1) the difficulty of procuring a suitable syringe; (2) manufacture of the serum with impure mercury; (3) the large dose of the serum. I have not found the vulcanite syringe answer in this country; the barrel works loose and the needles separate from the vulcanite. I now use an ordinary syringe made by WILKIN in which the needles screw on, I make the serum from Asa's chemically pure dental mercury, and never inject more than 5 minims at a time. With the man standing, I insert the needle high up near the crest of the ilium, and push it downwards and forwards. I have given about 900 injections and have never had an abscess. The men are able to perform all their duties and even to ride.

A CHINESE CHRISTIAN PHYSICIAN IN LONDON

The Friend of China says:—"An interesting incident of the year's work has been the visit of Dr. TSAO YUNG-KWEI, physician to the Special Envoy who represented the Emperor of China at the Diamond Jubilee of our beloved Queen. Dr. TSAO, who is on the staff of the Methodist Episcopal Missionary College in Peking, was entertained by the Society at an informal afternoon gathering in Westminster Town Hall, when an address of welcome was presented to him. He feelingly acknowledged the efforts made by British Christians to put an end to this great curse that afflicts his country. The address was afterwards engrossed and illuminated and forwarded to Dr. TSAO, at Peking, and we have received from him a cordial acknowledgment, stating that he is bringing the matter before the Christian churches in Peking. Amongst those present at the reception was Dr. WALLACE, of Calcutta Editor of the *Indian Medical Record*, which has subtitled the Report of Sir WILLIAM ROBERT, as Medical member of the Royal Commission, to the incisive criticism referred to in our last report. Dr. WALLACE confirmed the testimony of his Chinese confrères as to the evil effects of the opium habit."

ANGLO-INDIAN CLAIMS AND ASPIRATIONS

SURGEON-COLONEL KENNETH MACLEOD, M.D., F.R.S., writes:—"I observe from Indian papers, recently received, that the agitation for obtaining encouragement and recognition by the State for members of the Anglo Indian or domiciled British community in India is being actively carried on. Nothing but good can come of representing the numbers, the importance, the services, the capabilities, the loyalty of that community in this country, (England) and for the purposes of such representation strong and wide associations are needed. I see that a point has been made of the disabilities of the communities, as well as of their merits and capabilities; and accusations have been cast on the Government of India that these disabilities are the creation, not of circumstances but of arbitrary administrative initiative, actuated by prejudiced and unfounded disparagement of a people peculiarly placed, who have not been able sufficiently to assert themselves under the conditions of their existence in India. I am inclined to think that this point is overdone and that the circumstances are more to blame for the disabilities than the authorities."

PRESENTATION TO SIR WILLIAM STOKES, F.R.C.S.

An interesting ceremony, says the *British Medical Journal*, took place in the Royal College of Surgeons, Dublin, on Saturday, 24th May, when an address and some valuable plate were presented to Sir WILLIAM STOKES on the completion of his twenty-fifth year of office as Professor of Surgery in the school. The presentations comprised many old and valuable

papers, his colleagues and numerous officers, including Lord LANSLOW, Sir JAMES PAGET, and Professor OOSTER, of Aberdeen, who was able to be present. The chair was occupied by Sir WILLIAM THOMSON, President of the College, who made the presentation, and speeches were delivered by Sir CHARLES CAMERON, Sir GEORGE DUFFY, and Mr. MYLNE. Sir WILLIAM STOKES made a most effective reply, marked as it was by great eloquence; and he made touching allusion to the gift in Lady STOKES which accompanied the presentation. In the evening the Professor entertained their colleagues at dinner. Sir CHARLES CAMERON was in the chair, and there were also present Sir Wm. THOMSON, F.R.C.S., Sir GEORGE DUFFY, Professor OOSTER, Dr. JAMES LITTLE, Professor FRANKS, Mr. MYLNE, Dr. J. W. MOORE, Mr. HURSTON, and many others.

THE TITLE OF "DR."

The British Medical Journal says:—"At Newcastle, THOMAS PAINE HETHERINGTON, styling himself 'Dr.' but not on the *Medical Register* or holding any respectable qualification, was charged before the magistrates under the 40th Section of the Medical Act, 1858, with wilfully and falsely pretending to be a doctor of medicine. It was stated that the defendant was a dentist and a doctor of medicine of the United States. The case was however practically undefended, no evidence being called on behalf of the defendant, and who in the absence of proof that he held any medical qualification, was fined £20 and costs. The prosecution was instituted by the Medical Defence Union."

"At the Newcastle County Court, recently, before Judge GREENWELL and a jury, THOMAS PAINE HETHERINGTON (who, as above stated, was fined £20 at the police-court for illegally using the title of 'Dr.') was sued by the Society of Apothecaries for having practised without having a medical diploma. The jury found for the Society, and judgment was given against the defendant for the full amount claimed, £20 and costs."

THE "JOURNAL OF TROPICAL MEDICINE."

SAYS The Lancet—It is proposed, if enough support can be obtained for the scheme, to publish in London a monthly journal dealing with the diseases of warm climates, to be devoted to the publication of papers on tropical diseases and to the discussion of subjects scientific and practical affecting the interests of medical men in tropical and subtropical climates. The annual subscription, including postage, is to be 17s. We wish the promoters success in their new venture. They deserve it, for there is no country which has such a large interest in the tropics and the diseases common to them as our own. Any communication addressed to the Editors, *Journal of Tropical Medicine*, Messrs. JOHN SALT, SONS and DANIELSON, 85 to 89, Great Titchfield-street, London, W., will receive attention. The editors are Mr. JAMES CANTLIE and Dr. W. J. SIMPSON."

CLIMATE AND MORALS

A CURIOUS investigation has been undertaken by the officers of the weather bureau in the United States. Colonel WILLIS MOORE originated the investigation, believing that there is a close connection between the condition of the atmosphere and the physical and moral welfare of the people. The results of these investigations are as follows:—During the whole country during January, February, and March, there were in round numbers 1,800 suicides reported in the United States; while in July, August, and September there were 1,000. In the same period there were 1,500 murders in the cold term, as compared with 1,200 in the three hot months. There were 50 persons hanged in January, the three cold months, and 118 hanged in July, August, and September, the three hot months.

months. The investigation is said to have been instituted with the idea of issuing in the near future warning of the appearance of crime waves.

THE PLAGUE IN CALCUTTA. NO NEW DISEASE.

Cases of malignant fever of a distinctly fatal type and officially declared to be "sporadic plague," continue to be ferreted out of the dirtiest and most unhealthy plague spots in the city. From the date of the official announcement of this disorder as plague, 108 suspected cases have been reported and 81 have turned out fatally up to the 18th instant. There is considerable doubt as to all of these cases being of one and the same kind, or even one of the three different types of "plague," so that, as a matter of fact, while dysentery, cholera and famine-stricken people in *articulo mortis*, have been pronounced as cases of "sporadic plague," there is infinite difficulty in correctly stating, as a matter of indisputable truth, how many of these cases are real and how many are spurious. For all this, however, the city is condemned as a *plague infected* locality, and its commercial prosperity is doomed. We say doomed, because house-to-house visitation, if commenced fifty years ago, would have produced similar results in the discovery of certain types of malignant fever; and if the same process is continued for the next half century, there will be no dearth of discovery of similar cases, for as long as such festering plague spots as are at present to be found, exist all over Calcutta, so long will our unfortunate experiences of "sporadic plague" be monotonously unchanging. These are stern and solemn facts, and they can be borne out by the experience of the oldest living medical practitioners of the city and by the writing of still older though long departed ones.

INDIAN MEDICAL REGISTRATION IN PARLIAMENT.

It must be extremely gratifying to the Indian Medical Association to find that its laudable efforts to bring about the enactment of a Medical Registration Act for India are rapidly moving towards success. The fact that this important measure was considered by the General Medical Council of Great Britain at its last session, though with no very definite results, is still satisfactory. That its further efforts have resulted in a question being asked in Parliament, is another step in advance, and ought to encourage India and the local profession with the hope that the goal is approaching and victory is nigh. We quote the following paragraph from the *Lancet* of the 28th May —

"Sir WALTER LOWE, M.D., asked the Secretary of State for India on Tuesday, the 19th May 1896, whether he was aware that at present uneducated and unqualified persons have as much right to practise medicine in India as fully qualified practitioners, and whether in view of the danger to which the Indian people are thereby exposed, he would consider the advisability of instituting a system of registration for medical practitioners similar to that which exists in Great Britain and Ireland. Lord GEORGE HAMILTON replied. The answer to the first branch of the question is in the affirmative and that to the second branch in the negative. It would be, in my judgment, impossible in the present condition of India to prevent the people of that country from resorting to native practitioners, even though they may be regarded by Europeans as not fully educated or qualified for the work they undertake."

HAVE THE PUBLIC FAITH IN OFFICIAL COMMITTEES?

In answer to the above question, Reuter telegraphs — "The Governor of the Bank of England, in a letter to Lord GEORGE HAMILTON, says that the majority of the Indian Currency Committee consists of officials, and as now constituted, the Committee fails to command the confidence of the city."

In spite of the fact that under the new "Sedition Act," anything "from winking one's eye to damning the Viceroy" may be construed into sedition, we daresay in answer to the question that heads this comment, the public have no

faith in the Bengal Plague Commission, the majority of whom are officials, who, as a matter of fact, are putting their heels in Darjeeling, and whose ~~thought~~ ^{thought} in connection with plague matters in Calcutta, may be summed up in a little word of three letters — *W.H.* Where is the Bengal Plague Commission! Echo answers: *where?*

ROYAL COLLEGE OF SURGEONS IN IRELAND.

SAYS the *British Medical Journal*:—"The election of President, Vice-President, and Council will take place on the first Monday of June. Mr. E. L. SWAN, Surgeon to Stevens's Hospital, will succeed to the presidential chair, which has now been occupied for two years by Sir WILLIAM THOMSON. For the vice-presidency, which becomes vacant by Mr. SWAN's promotion, there are two candidates, Dr. C. B. BAIN, Regius Professor of Surgery, Trinity College, and Mr. THOMAS MITCHELL, Surgeon to the Richmond Hospital. It is believed that the contest will be very close. For the Council Mr. H. G. O'ROLY, Mr. M'CAUSLAND, Mr. ROBERT H. WOODS (who retires from the secretaryship to Council), Dr. CRAWFORD, Mr. CHAWON, and Mr. J. HARRISON SCOTT will be candidates."

WHERE LIFE IS LONGEST.

Of all the countries in the world, says the *Philadelphia Medical Journal*, it is Serbia which contains the most centenarians. In this little country, which has less than 1,800,000 inhabitants, there are actually 575 persons whose age exceeds 100 years. Ireland comes next in the list with 578, but then her population is very much larger than that of Serbia. Spain has 401 out of a population of 17,000,000, and France counts 213 among her 38,000,000 inhabitants. England, Scotland and Wales can only muster 193 between them, and Germany with her enormous population of 55,000,000, has but 78. Norway has 23 out of 2,500,000 inhabitants and Sweden a population of nearly 5,000,000, and only 20 centenarians. Denmark has but 2, and in little Switzerland there is not a single person whose years number five score.

CHLOROFORM SYNCOPE RESTORED BY ARTIFICIAL RESPIRATION AND NITRITE OF AMYL.

In the *Lancet* of 19th September 1891, page 665, EDWARD RICE, M.D. London, of Oxford, reports a case of chloroform syncope restored by nitrite of amyl and artificial respiration. The subject was a woman, 40 years old, and was chloroformed through a Junker's Inhaler, for the purpose of having a growth excised. Three drachms of chloroform were inhaled and syncope ensued. Dr RICE insists that the pulse failed first and then the respiration. Immediately artificial respiration was resorted to, and a capsule containing three minims of nitrite of amyl was snapped and applied to her nostrils. An enema of brandy and water was also given. These means restored her. The patient had taken suicidal freely the previous night.

BEWARE OF TABLOIDS. DEATH BY MISTAKING ONE FOR ANOTHER.

THROUGH an error on the part of a chemist in Melbourne, who substituted sulphate of atropine for muriate of morphine, Dr. S. I. Williams met with a tragic death. He was on his way to visit a lady patient, and stopped at a chemist's to obtain some morphine solution. The chemist made a solution with atropine instead, and the doctor, who was in the habit of taking morphine largely, gave himself an injection before entering the house. After administering a dose to the patient, he gave himself a second injection and immediately afterwards became ill, then unconscious, and after lingering a while, sank and died. The patient also exhibited symptoms of poisoning, but recovered.

[illegible]

Dr. BOMFORD, President of the Medical College, and the late Surgeon-Lieutenant-Colonel J. F. MCCONNELL, who was for many years connected with the College as a Professor, were performed on Monday, August 18, 1896, by Surgeon-Lieutenant-Colonel Edward B. BOMFORD of the College, in the main hall of the new building known as Chooney Lall Seal's Dispensary, situated on the grounds south-east of the College. There was a large attendance of the students, and of members of the medical profession. On Dr. BOMFORD being voted to the chair, the Honorary Secretary of the MCCONNELL Memorial Committee read a short report of the work done by the Committee for the purpose of perpetuating the memorial of the late Professor to whom it was decided to erect a brass memorial tablet. The Committee was indebted to Dr. BOMFORD for his valuable advice and assistance, and for securing the site of the tablet in the Chooney Lall Seal's Dispensary. The Committee also tendered their thanks to Dr. R. BIRD, Dr. J. F. EVANS, Dr. KEDAR NATH DASE, and others, who have helped toward the erection of the tablet. In conclusion, the Secretary requested Dr. BOMFORD to unveil the tablet which is inscribed as follows:— "To the memory of Brigade-Surgeon-Lieutenant-Colonel JAMES FREDERICK PARRY MCCONNELL, M.D., F.R.C.P., L.M.S. for many years on the staff of this hospital, first as Resident Physician and Professor of Pathology and afterwards as second physician and Professor of Materia Medica. Born 18th January 1848, died 24th, August 1896. Erected by the students of the Medical College in token of their esteem and regard for one whom they revered as a teacher and loved as a friend." Before the unveiling ceremony was performed, Mr. WOOD read a letter from Mrs. MCCONNELL, who expressed her grateful acknowledgment of the kindly feeling which prompted the students to raise a permanent memorial to her husband's memory. Dr. BOMFORD, after unveiling the tablet, which occupies a prominent position in the main hall of the new building, addressed the assembly. He paid a generous tribute to the high attainments and medical skill of Dr. MCCONNELL. He had won the esteem of both his patients and the students of the College, in whose education and welfare he always took a deep interest. With the customary vote of thanks to the chair the proceedings terminated.

PLAGUE IN BOMBAY AND IN THE PUNJAB.

THE plague figures for the past three days shows that on Saturday there was 5 new cases and 2 deaths; the mortality from all causes being 79, being the same figures as those on the corresponding day last year. Sunday's returns show 18 new cases and 1 death. There were 68 deaths from all causes. On the corresponding date last year there were 7 seizures, with 4 deaths, and 91 deaths from all causes. To-day there were 2 fresh attacks and 4 deaths. There were 60 deaths from all causes. On the same day in 1897 there was 1 seizure. The plague deaths numbered 4, while those from all causes were 68.

The returns for the 12th instant for Karachi show 16 cases and 18 deaths; the totals to date being 2,849 cases and 2,287 deaths.

The plague returns from the infested area continue to be satisfactory and are re-assuring in both the Jullunder and Moinsapore districts of the Punjab. The returns of the 7th and 8th instant show no fresh cases and no deaths. Four villages are declared free of plague.

TO DISGUISE BITTER TASTING MEDICINE.

THE N. Y. Medical Record says:—"A plant grows in Assam, the botanical name of which is *Gynemna sylvestre*, which has the peculiar property, when chewed, of temporarily neutralizing the sense of taste as regards sweet and bitter things, while that for sour and saline substances remains unaffected. The Hindus claim that the plant is an antidote to snake-bite. "However that may be, it is believed that the plant might be advantageously introduced in our pharmacopoeia as a means of disguising the bitterness of quinine and other disagreeable medicines."

ANOTHER ANGLO-INDIAN SUCCESS.

Among the passengers who embarked from Madras the afternoon before the S. S. Anson for England was Mr. W. C. Brown, a son of Mr. JOHN Brown, the Presidency Town Magistrate and a pupil of the local medical college. Mr. Brown is an Anglo-Indian, and headed the list of the recom-

He was a member of the first expedition to the Arctic region, and was the first to discover the gold mine at the mouth of the Yukon. He was also the first to discover the gold mine at the mouth of the Yukon. He was also the first to discover the gold mine at the mouth of the Yukon.

THE I. M. S. AND THE NEW MEDICAL REFORM BILL.

Fortnight officially has yet reached India regarding the manner in which the Indian Medical Service will be affected by the re-organization of the Army Medical Staff. Presumably, says the *Pioneer*, the Secretary of State will send out a despatch on the subject shortly. It is not known when the new Warrant will be issued, but in the House of Commons a fortnight ago, Mr. Powell Williams stated that the delay was in regard to the settlement of "some minor points which required reference to India."

UNQUALIFIED MIDWIVES.

The opinion of Mrs. Garrett Anderson, who may be supposed to represent the best opinion of her own sex, and who writes with full knowledge of the fact, that if all women are to have skilled attention, the majority must now and always be attended by men, strongly objects to the measure, and fully recognizes the danger of labeling a whole host of unequalled women, and a handful of very intimately qualified ones, with any title whatever implying a Government guarantee.

THE ACTING PRINCIPAL OF THE CALCUTTA
MEDICAL COLLEGE

SURGEON-MAJOR G. F. A. HARRIS, D.S.O., L.R.C.P. Lond. (1878), M.B.C.S. Eng. (1877), who has been appointed to act as Principal of the Medical College Hospital while Dr. Seaford is away on furlough, has hosts of friends. He was a great favorite in Stirling society some eight years ago, when he was Civil Surgeon there. In musical circles Dr. Harris has proved quite an acquisition, and his delightful performances on the violin are pleasurable remembrances of many enjoyable evenings on the hills. But he is a thoroughly good practical physician as well as a trained medical administrator.

SHORT ITEMS.

A heavy disbeliever, who had suffered for years with symptoms of gastric atony, frequently vomited, and on several occasions found worms in the ejected material. These proved to be larvae of some species of fly. Buchmann prescribed an infusion of Persian insect-powder, with the result of finding in the stools masses of dead and partially digested larvae. The patient had no further symptoms.

The 1st January 1900 has been fixed for the awarding of the Samuel D. Gross prize of \$100 for the best original essay founded upon original investigation on some subject in surgical pathology or surgical practice. Only American citizens may compete, and the essay must not exceed 150 printed pages, octavo size. Further particulars may be obtained from D. J. Kwing Mears, 1429 Walnut Street, Philadelphia: Pa. U. S. America.

An exchange reports that in an examination that was made of some "electric bells" sold by a street fakir, it was found that beneath a strip of gauze was a layer of dry mustard. When the wearer perspired a little, the mustard was moistened and set up a burning sensation, and the deluded victim believed a current of electricity was passing through him.

The half-yearly examination for the Fellowship of the Royal Colleges of Surgeons in Ireland came to a conclusion by a conference on 21st May. The number of candidates was unusually large and included a lady graduate in medicine of the University of Calcutta. Miss Cohen passed and was entered on the roll as a Fellow of the College, she being the third lady who has received such honor.

Premature burial, it is reported, will share a large share of attention in the medical section of the National Exposition which will be held at Tunis, in Italy, this year. The object in view is to induce all countries to make laws requiring corpses to be kept for a fixed period before cremation or burial.

Assetan pharmacists ought to make a good thing of it while the people are many and the pharmacists few. Thus while Vienna has a population of 1,014,100, it boasts of 106 pharmacists or 1 for every 14,580 inhabitants. Kusolzeuthal with her 32,586 souls has but one pharmacy and the proportion of pharmacists to inhabitants is as 1 : 10,581 in Badenau.

Any person who spits in a street car or public building under Government control in the District of Columbia is liable to a fine of \$10. California carries things a bit further and the other day sentenced a millionaire to 24 hours' imprisonment in the San Francisco Jail, for spitting where he shouldn't.

In commemoration of the Queen's Diamond Jubilee, the American community in England has presented £1,000 to each of the five leading hospitals in London for the "endowment of a bed in perpetuity" on condition that Americans will be given the preference, though the beds may be used by any one else.

The Mysore Government have put an end to the exclusive privilege of distilling sandalwood oil in that State by rejecting the application of a Coonor distiller, Mr. H. S. Lee, who applied for the monopoly for a period of ten years. The monopoly granted to Mr. F. P. Hay, of Hunsur, some years ago, was cancelled in 1898.

A warrant has been issued for the arrest of Pilot Simmonds, of the Rangoon Service, on a charge of defaming Surgeon-Lieutenant-Colonel Thomas, Civil Surgeon and Port Health Officer of Rangoon. The accused, it is alleged, cast reflections upon the manner in which the inspection of female passengers from Calcutta was conducted.

A New York doctor sued a lady patient to recover \$80 for professional services. She opposed his claim as exorbitant and has raised a counter-claim of \$100 for "time lost" as she alleges that the majority of the doctor's visits were more of a social than of professional nature.

The will, with two codicils, of Sir Richard Quain, Bart, M.D., F.R.C.P., &c., who died on 13th March, has been proved by his brother, Mr. F. Quain, of Mincing Lane. The testator's gross estate is sworn at £118,121 13s. 2d., the net personality being £116,820.

Sir William Thomson, President of the Royal College of Surgeons in Ireland, was entertained at dinner by the Vice-President and Council on Saturday, 14th May, in the Shelbourne Hotel. The chair was occupied by Dr. R. L. Swan, the Vice-President.

In case of delirium tremens Crothers uses in the early period, free bathing and catharsis without narcotics. When exhaustion and sleep come on, the latter is encouraged and strychnin nitrate is given as a stimulant. Physical restraint should not be used, unless absolutely necessary.

Ribbert calls attention to the parasitic nature of tumors. The individual cells appear to have all the qualities of parasites, growing independently in the host, excepting that they prey upon it for nourishment without regard to the conditions necessary for its well-being.

I have not failed once for many years, by putting a blister over the fourth and fifth dorsal vertebrae, to put an end at once to sickness of pregnancy during the whole remaining period of gestation, no matter at what stage of the case I was consulted." So says Professor Parvin.

The Calcutta Homoeopathic Medical School has just passed twenty-one students as Licentiates, 5 in the First and 16 in the Second Division, among whom one comes from the Punjab. This School of Medicine will be opened on the 22nd within introductory address. This is another Indian Diploma will not under State control.

Mr. Charles Stansmore Toms, F.R.C.S., F.R.S., L.R.S., has been nominated a Crown Member of the Council of Medical Education and Registration of the United Kingdom in the vacancy created by the death of the late President, Sir Richard Quain.

The Colonial Office has received a telegram reporting that during the week ending 21st May there were 112 cases of plague in Hong-Kong and 107 deaths resulting from the plague. These figures show some decrease in the ravages of the disease.

The Ohio State Legislature are trying to pass a "bill" for the castration of any man who is convicted of criminal assault on a female and particularly upon any girl under fourteen years of age.

With the waning of the plague in Bombay, the Plague Committee there has been abolished and the Municipality is responsible for the sanitation of the city and affairs generally connected with the Health Department.

Surgeon-Major G. F. Harris, Civil Surgeon of Nagpur, succeeds Surgeon-Lieutenant-Colonel G. Bomford, who takes one year's furlough, as Principal of the Medical College, Calcutta.

Cardinal Gibbons, Bishop Faret and several prominent citizens of Baltimore have started an antivivisection crusade, which is particularly directed against the medical school of Johns Hopkins University.

Ausonia has at last adopted a medical examining board, while veterinary surgeons are not permitted to run dry stores in Missouri unless they have qualified and registered as pharmacists.

He was a very able linguist and one day a friend said to him: "They tell me professor that you have mastered all of the modern tongues." "Yes," replied he, "all but two my wife and her mother."

"Know syphilis in all its manifestations and relations," says Dr. W. Osler of Philadelphia, "and what remains to be learned will not stretch the pia mater of a megaloccephalic senior student."

There is every probability of Surgeon Lieutenant-Colonel Franklin succeeding Surgeon-Lieutenant-Colonel Kaye as Inspector-General of Civil Hospitals, Punjab, when the latter proceeds home on furlough.

In septic conditions the patient is often very uncomfortable by reason of dryness of the tongue. A bit of ordinary chewing-gum will usually start the oral secretions and in a very short time give relief.

The Madras Government has sanctioned an outlay of Rs. 1,70,000 for the construction of quarters near the Memorial Hall for the accommodation of the Apothecaries attached to the Madras General Hospital.

Surgeon-Colonel K. MacLeod, Professor of Military Medicine, Army Medical School, Netley, was presented to Her Majesty on the occasion of the Queen's recent visit to Netley Hospital.

The Council of the British Medical Association have just completed the purchase of the freehold site upon which are situated their premises at the corner of Agar Street, and the Strand. The purchase-price was £75,000.

Special leave for six months has been granted to Surgeon-Lieutenant Colonel G. Ranking, M.D., Secretary, Board of Examiners, with effect from 1st July next.

Surgeon-Major D. G. Crawford, Civil Surgeon of Monghyr, has been appointed to succeed Surgeon-Captain Pilgrim as officiating Civil Surgeon, 24-Parganas.

Surgeon Lieutenant-Colonel C. J. H. Warden, I. M. S., Medical Storekeeper to Government, Bengal Command, is granted two years' furlough.

Surgeon-Captain B. B. Grayfoot, I. M. S., officiates as Medical Storekeeper, Bombay Command, *vice* Surgeon-Lieutenant-Colonel J. Parker, on leave.

Dr. Gustmann, of Frankfort, has published a monograph showing that no less than 80,000 school-children in the German Empire suffer from stuttering.

Professor von Esmarch, who is over 76 years old, has announced his intention of resigning the chair of surgery which he has held at the University of Kiel since 1857.

Dr T. C. Hayes has been elected Professor of Obstetric Medicine and Diseases of Women and Children, and Dr. John Phillips, Lecturer in Practical Obstetrics in King's College.

The Lord Mayor's dinner in support of the London Hospital last week resulted in the collection of £75,000, with annual donations of over £4,000.

Professor Michael Foster will preside over the meetings of Council of the British Association to be held next year at Dover.

Brigade-Surgeon Lieutenant-Colonel W. Flood Murray, Civil Surgeon of Shahabad, has been allowed privilege leave for ninety days, from the 1st instant.

Surgeon-Major J. Grainger, on return from military duty, has been appointed Civil Surgeon of Champaran, during the absence, on deputation, of Surgeon-Major R. B. H. Whitwell.

Danner records a case of external feminine pseudo-hermaphroditism, the patients being 33 years old and of Italian descent. After marriage she became twice pregnant.

Surgeon-Lieutenant-Colonel W. Coates, M.D., Civil Surgeon of Lahore, proceeds on six months' leave, and is to be succeeded by Surgeon-Major J. A. Cunningham from Multan.

A very red tongue indicates the need of acids in the system. Five drops of dilute nitro-hydrochloric acid in water fills the want satisfactorily.

Brief Pointers — Whipped raw eggs possess great nutritive value, and are very easily digested.

Assistant Surgeon P. S. Blaker, of Calcutta, has successfully passed the M.R.C.S. England.

Mr. A. R. Khan has successfully passed the first professional examination of the University of Edinburgh.

Brigade-Surgeon-Lieutenant-Colonel W. McConaghy, Bombay, officiates on the Administrative Staff of the Army.

In future, physicians practising in any part of the State of Texas must pay an "occupation" tax.

On return from military duty, Surgeon-Captain E. Herald Brown, M.D., has been re-appointed Civil Surgeon of Purneah.

DEPARTED INDIAN WORTHIES.

DEPUTY-SURGEON-GENERAL S. B. PARTRIDGE,
F.R.C.S., C.I.E., Q.E.S.

Bengal Medical Service (Retired.)

On 11th May, in the presence of relatives, brother officers, and friends, the mortal remains of SAMUEL BOWEN PARTRIDGE were laid to rest in the cemetery at Norwood.

This distinguished medical officer was born at Cardiff in 1828 and was educated at King's College, London, where he had a most brilliant career, during which he gained many prizes. After passing the Royal College of Surgeons he entered the East India Company's service on the Bengal establishment as an Assistant Surgeon in the year 1852. Shortly after his arrival in India he was ordered to Burma to join the Bengal Field Force, and after performing excellent service in a variety of ways, on his return to Bengal he served as Civil Surgeon and also with a cavalry regiment. On the outbreak of the mutiny in 1857 he served with a cavalry regiment in Oudh, and when the siege of the Residency of Lucknow commenced he served throughout the whole of that eventful period in Dr. FAYRE's house in the garrison, where his energy, activity, and professional knowledge were of the greatest benefit. He was present with the expedition under Colonel BURNES, in which several officers were killed, and he also accompanied the ill-fated expedition to Chinbut, where he had a narrow escape of losing his life. Subsequently he distinguished himself as Field-Surgeon in the operations under the Commander-in-Chief at the recapture of Lucknow. For these services he received the brevet promotion of Surgeon, was allowed to count a year's service, and received the thanks of Government in general orders.

The state of his health after all these exceptional services rendered it necessary for him to return to England. After a short stay, during which he became a Fellow of the Royal College of Surgeons, he resumed his duties in India, and was then appointed to the Medical College of Calcutta, in which he had on a former occasion officiated for a short time, as Professor of Anatomy and Surgeon of the Medical College Hospital. He was also an Examiner in the University of Calcutta, a Member of the Senate, and for a short time President of the Medical Faculty of the University. Subsequently, on the retirement of Dr. FAYRE, he succeeded to his appointment as First Surgeon and Professor of Surgery in the Medical College Hospital, which appointment he continued to hold with the greatest distinction. In addition he had an extensive practice in Calcutta until 1880, when he retired from the service.

After his return to England Deputy Surgeon-General PARTRIDGE was appointed member of the India Medical Board at the India Office, where he rendered most valuable service, until loss of sight made his resignation of that appointment necessary, to the deep regret of his colleagues and friends.

The news of his death will be received in India, as it has been in this country, with the greatest sorrow. He was held in the highest esteem by everyone who knew him; no man was ever more deservedly loved and respected than he was. His intellectual powers were great, and he was as much characterised by the breadth as by the accuracy of his knowledge; most laborious in his studies, most persevering in pursuing to the end any object which he had undertaken; with the profoundest mathematical problems as with the simplest piece of mechanics he was equally at home. As an anatomist he was unrivalled in the clearness of his demonstrations; as a surgeon he was remarkable not only for his skill as an operator but for his great powers of diagnosis, nor

was his incomparable for his capacity for dealing with disease in its tropical and other forms, whilst his firm, gentle, and patient method of treatment inspired all who came under his care with confidence and affection. Notwithstanding his great attainments and his remarkable intellectual power, he was as humble as a child. The simplicity of his character was not less marked than its strength. He was naturally beloved by all his brother officers, associates, and pupils, and in fact by everyone who knew him. Whilst so gentle and tender in every way, a rock was not firmer than he where firmness was required. Not even HAYWARD himself, or OUTRAM (with whom he was justly compared) better deserved the title of "Chevalier sans peur et sans reproche."

On Deputy Surgeon-General FAIRBANKS's retirement from the India Office the Government signified their approval of his services by creating him a Companion of the Indian Empire. He had previously been made an Honorary Surgeon to the Queen, and had also received a medal and clasp for Burma, and a medal and clasp for the siege and for the capture of Lucknow.

ALFRED JOHN WALL, M.D. LOND, F.R.C.S.
Indian Medical Service (Retired)

DR. WALL, whose death was announced a few days ago, was the son of a medical man who had a large practice in the West End of London. He was born in 1847, and after receiving his preliminary education at Epsom College, matriculated at the University of London in 1865; he then entered St. Mary's Hospital, where he was known as a hard worker and won a number of prizes. In 1868 he gained the Scholarship of Anatomy of his school, a distinction which carried with it the title and duties of Assistant Demonstrator of Anatomy. In 1870 he was appointed Resident Medical Officer of the hospital, becoming Resident Obstetric Officer in 1871. He took the degree of M.B. in 1871, that of B.S. in the following year, and that of M.D. in 1878. In 1872 he became a Fellow of the Royal College of Surgeons of England by examination. He took a high place in the examination for the Indian Medical Service in 1873, and almost immediately on his arrival in India in the early part of 1874 he was appointed Resident Medical Officer at Bhaugulpore.

In 1875, when the Snake Poison Commission was appointed, Dr. WALL was offered a seat on it. The greater part of the practical work of the Commission fell upon him as the youngest member. He held the position for three years, and then, in consequence of failing health, he sent in his resignation. He was twice asked to reconsider this step, but when he adhered to it, he received a letter of thanks from the Government for the valuable work he had done, and was given his choice between an appointment as Residency Medical Officer in Nepal and Deputy Professor of Anatomy in Calcutta. Consideration of health led him to choose the former. Some time afterwards, when travelling on furlough, he contracted malarial fever, which became complicated with pneumonia. In consequence he came home invalided, and never recovered sufficiently to return to India.

In 1888 he published a book entitled *Indian Snake Poisons*, which made his name widely known. He next took up as a subject of special study the cholera, and followed successive outbreaks of the disease over Europe. In Italy and Sicily he was especially distinguished for his services during these. The Municipal Council of one town presented him with an address and the freedom of the town in recognition.

In 1898, as a result of those travels and investigations, he published a book on *Asiatic Cholera*, which was favorably received.

He had always been an indefatigable student of pathology, and he now turned his attention still more closely to it, working at it for many months together in Bonn, Paris, Berlin, and Paris.

In December 1897, he left England with the intention of going to the Riviera, in the quiet there to put his pathological notes into form. But whilst staying in Paris a rally he became so ill that by the advice of a specialist whom he consulted he returned to England and asked his sister to go to Hastings with him.

His condition became so much worse that on 31st April he was brought up, under care, to London, and after consultation with Dr. SAVAGE was placed in charge of a trained attendant under the care of a medical man. On Wednesday, 27th April, he managed to escape from his attendant by going out another way from St. George's Hospital, where he had gone, he said, to call upon some friends on the medical staff there. Although the police were at once communicated with in London, and telegraphed to stop him at the ports of Dover, Folkestone, Harwich, and Newhaven, nothing was heard of him by his friends until the following Monday, when, in consequence of information received by his sister, she went down to Guilford, and identified a body lying there as that of her brother. He had made his way there the previous Thursday and early in the morning had ended his life by stabbing himself to the heart. A *post-mortem* examination showed that Dr. WALL was suffering from thickening of the membranes of the brain, and this, together with the evidence his sister was able to give at the inquest that evening, caused an immediate and unanimous verdict of "Whilst of unsound mind" to be returned, in which the coroner fully concurred.

Another St. Mary's man and intimate friend of Dr. WALL from student days writes of him—

"In manner he was diffident, quiet, and retiring. He was extremely well informed in every subject of art, science, and literature—the best possible of companions. He talked German, French, and Italian fluently, and was keenly interested in the politics as well as the literature of the countries in which he made his home."

His brilliancy of mind continued to the last, and even whilst under medical care and restraint he captivated all whom he came in contact by his mental power and gentleness of demeanour. Throughout his life Dr. WALL had been singularly abstemious, and of very regular and quiet habits.

SURGEON-GENERAL JAMES IRVING, M.D.

Indian Medical Service (Retired).

THIS officer died at Clifton on 3rd May at the age of 75. He was born in Edinburgh in 1828 and after graduating in the University of that city in 1843, entered the Bengal Medical Service in 1847. He attained the rank of Deputy Surgeon-General in 1874, and retired with the honorary rank of Surgeon-General on 18th December 1879. He served with distinction throughout the Indian Mutiny. Most of his executive service was spent in the North-West Provinces, where he held important civil charges. For many years he filled the responsible office of Civil Surgeon of Allahabad, and gained a high reputation as a skillful physician and surgeon. Under a somewhat testy manner he concealed a kindly disposition and most charitable heart, and his advice and aid were eagerly sought and highly valued by those in sickness or trouble. He was an observant man and hard worker, and contributed several papers to the medical press, the best known being *Observations on the Falcx* caused by the Vetch (*Lathyrus sativus*).

His administrative life was spent in Bengal. He was the first Surgeon-General of the combined provinces of Bengal, Behar, and Orissa when the separation took place in 1876 between military and civil medical administration. His work in this capacity was characterized by competence, independence, and shrewdness. Since his retirement he has lived a quiet life, devoting himself to labors of charity and kindness. He was emphatically a conscientious, good man, able without, and devoted to his profession.

SANITARY MEASURES IN INDIA.

IV.

According to the death-rate of Madras, averaging, since 1873, 52.66 per 1,000, is considerably larger than that of other Sanitary or Calcutta, the information and particulars given in the volume on "Sanitary Measures in India" as to the sanitary condition are much more fragmentary and meagre than in the cases of those cities. For some unexplained reasons the report of the Health Officer for Madras is not published therein, and the report of the Madras Municipality is published without that part treating of its insanitary conditions.

Perhaps the insanitary condition of Madras, given in the compressed reports, is, in the opinion of the Indian authorities, too disgraceful to be made public, but, after the revelations published as to Bombay and Calcutta, if this is the case, it is very much resembles straining at a gnat and swallowing a camel.

The year 1894 was, for Madras, a comparatively healthy one, the death-rate being the lowest since 1885.

The Army Sanitary Commission remarks on the subject "It is evident from the small sums expended during the year in improving the drainage and water supply of the city, that no substantial progress has been made towards remedying the radical defects in either, only £6,849 10s. having been expended on the former and £6,863 on the latter. The drainage scheme proposed by Mr. COUSINS may be excellent, but it is very expensive, and the municipal authorities may be excused if they hesitate to undertake a work estimated at £280,000, until after they have become convinced that the effectual drainage of their town cannot be carried out at less expense. When once the main arteries of a good sewerage system are laid down, the sanitation of the town will be much simplified.

A water supply scheme has also been proposed by Mr. COUSINS; but as this would involve an annual expenditure of £40,000, it is considered beyond the utmost strain that the municipal finances could bear. It is clear from the description given of the water supplied to the city that this should undergo filtration before distribution; but as it has not a sufficient head to admit of its being conveyed on to the filter beds unless first lifted by pumping, and as the cost of this would be prohibitive, the difficulty seems to be for the present insurmountable.

Other improvements having for their object the more efficient removal of night soil and refuse, the prevention of intemural burial, the opening up of overcrowded parts of the town, the admission of sea water into the stagnant and fetid Cooum river, and such like, need not be interrupted because of the delay in arriving at a decision regarding the proposed drainage and water supply. But until these latter are undertaken and carried out, Madras will almost certainly continue to enjoy the unenviable reputation of being the unhealthiest of the three Presidency towns. All other improvements are of comparatively minor importance, and their effects, as measured by the death-rate, will probably be inappreciable.

The death-rate fell from 41, in 1893, to 36.5 per 1,000, but was still considerably higher than that recorded in the other two Presidency towns, although in these latter the year was an exceptionally unhealthy one. Of the chief diseases, fever was, as usual, credited with the larger share of the deaths. Although less fatal than during the preceding year, the mortality caused by it was much in excess of the average for the previous 10 years. Until Madras is provided with an efficient drainage and sewerage system, diminution in the annual mortality from fever need not be looked for. On the contrary, as pollution and sewage logging of the soil must go on increasing in the absence of effectual drainage, the death-rate from fever may be expected to likewise increase. The mortality from dysentery and diarrhoea, although high, was below the average. The indifferent quality of the water supply doubtless favours the prevalence of these diseases.

The number of deaths in 1894 was 16,842, a decrease of 2,468, or 11.42 per cent. under 1893; of 1,706, or 20.65 per cent. under 1892; of 7,304, or 29.6 per cent. under 1891; and of 1,021, or 5.79 per cent. under 1890. The death-rates per 1,000 were, in 1894, 36.5; in 1893, 41; in 1892, 42; and in 1891, 43. As in the case of Bombay, statistics date from 1874, and the average death-rate per 1,000 for the period

1874-94, is 43.74. The highest rate, 59.9 per 1,000, was in 1877; the nearest to the average, 42, in 1893; and the lowest, 34.7 per 1,000, in 1879. Dividing the whole period into three terms of seven years gives an average death-rate of 52.73 per 1,000 for 1874-80; of 40.17 per 1,000 for 1881-87; and of 42.88 per 1,000 for 1888-94. Dividing the period into seven terms of three years, there was considerable fluctuation, the highest rate, 64.8 per 1,000, being in 1877-79; the nearest to the average, 42.6 per 1,000, in 1874-76; and the lowest, 37.8 per 1,000, in 1890-92. Bearing in mind the necessary caution as to the value of registration statistics in India, these figures show a great improvement in the middle period which was not kept up in the third period.

The great difficulty in dealing with the problem of Madras sanitation lies in the fact that the high death-rate is not the result of any one cause, but of a combination of nearly all the causes that affect mortality all over the world. The most important, briefly, are, an insufficient water-supply, defective drainage, and, over a considerable portion of the municipality no drainage at all, a system not loaded with organic impurity, a putrid and disgusting fetid water rising comparatively near the surface, what in other places is some parts of the town, crowded premises for the poor, overcrowded and ill-ventilated houses for the middle classes, in many cases directly connected with the surface water by wells in their interior, burial grounds and slaughter houses in the city, and lastly, the general squalor, conjugal, and religious habits of the people. These are matters which can only be remedied by a heavy expenditure of money and years of systematic and patient work. There can be no doubt that the high death-rate is due to local conditions and not to climatic influence, for both Europeans and natives who live in well-built houses in the better parts of the town, and are properly clothed and fed, enjoy a comparative immunity from disease and death.

The chief causes of death in Madras were fever, dysentery, and measles, and formed 52.66 per cent. of the total. Deaths from fever, 37.05 of the whole, were 5,128, a decrease of 500, or 8.02 per cent. under 1893. Although this is an improvement, it cannot be considered satisfactory, as it is still far above the average. The death rate per 1,000, 19.5, fluctuated from 8.5 in the Eighth Division, South Ward, to 31.7 in the Third Division, Centre Ward. The mortality was much less in the rural and suburban areas in the south and south-west of the municipality, where aggregation is less, and there are plenty of trees to dry the ground, than in the crowded area of Black Town.

The general conditions which produce a heavy mortality from fever in Madras are the general insanitary conditions which prevail, especially those due to the want of good drainage and pure air. The result is materially affected by the want of ventilation and overcrowding of houses, in which people breathe air vitiated by organic matter given off by the lungs and skin mingled with which are the gases from the sewage-polluted grounds and from the drains both inside and in the streets beneath the door and windows.

It is a matter of the greatest difficulty to diagnose a non-eruptive fever among people who rarely attend a hospital or avail themselves of the ministrations of a medical attendant of any grade, and who, for the most part, die in their parishes without being seen by anyone but their relatives.

According to a report of Mr. COUSINS, who visited Madras and examined the drainage and water-supply, Madras is drained on the open-channel system, that is, the drainage of the houses is discharged into open channels in the street, some of which are formed in the soil without brickwork, concrete, or any proper construction, whilst others are of defective brickwork with open joints, &c.

The open channels in Black Town and a few other parts of the district have been recently reconstructed in a very superior manner to those generally found. Under the system now pursued, all rubbish, dust, ashes, and the principal part of the solid excrementations are collected and removed by the conservancy carts and disposed of in various ways. The fouled water from the houses, the urine, part of the excreta mixed with the water used for the daily washing out of privies, bath, and sink water, &c., are discharged through the house drains into the open drains in the street.

House drains are usually constructed of very imperfect brickwork, having open joints and generally laid but a few inches below the level of the floors of the houses with

insufficient gradients. The soil for some distance round these drains must of necessity be saturated with sewage, which must infallibly affect the health of the occupants. These drains usually terminate at the front walls of the houses at a height of 2 or 3 feet above the public drains in the street; here the sewage pours or trickles down the surface of the front walls of houses until it reaches the open channel, which conveys the sewage to a large open drain. Then it passes on into other wider and deeper drains, until, eventually, it is discharged into covered sewers, which convey the sewage to pumping station where it is pumped on to one or other of the 11 sewage farms.

When the engines or pumps at these stations are not at work, or if there is more sewage than the land and pumps can deal with, the overflow at such times is discharged directly either into the River Cooum, the Buckingham or Junction canals, or into the sea.

In some parts drains are found which do not connect with sewage farms, but empty their contents into the river and canals or stagnant pools. Thus the sanitary aspect of a Madras street presents the spectacle of a row of open house drains on either side of it discharging sewage matter into two open public drains. It is no matter for wonder that in all parts of the town the subtle odor of sewage, more or less strong, is distinctly apparent; and when the abnormally high death-rate accelerated by these insanitary conditions are considered together with the moral effect which the constant sight of the filth must have on the native mind, no more crushing arguments against the open channel system could be adduced. One disgusting practice alone under this system should be sufficient to ensure its abolition—the present method of the collection of the faeces by men and women.

If no back entrance exists to the house, the native must enter the back yard by a small covered inlet generally provided with a door. This opens from the street to the privy, where the man or woman collects the excreta of the household and conveys it to the pails in the carts in the streets, which are provided for its removal to the depot. The privy is generally washed out at the same time, the fouled water going into the open drain in the street. I cannot speak too strongly against such a repulsive and loathsome practice. To the inhabitants it must be a source of supreme disgust, while its degrading influence upon those carrying out such work cannot be over-estimated.

Even in Black Town, where the open-channel system is seen at its best, the concurrent evils can be plainly noted; but in other parts, where, either through choked-up channels or insufficient gradients, the sewage remains stagnant or soaks through badly constructed or broken drains into the subsoil, the evil effects are patent to all.

A large proportion of the native population are shopkeepers; these, with their assistants sit month after month vending their wares in the impure atmosphere arising from the open drain immediately in front of their shops, while their customers stand over the same foul-smelling channel to make their purchases. The wonder is, not that the mortality returns are so high, but that they are so low under these conditions.

The solid contents of the sewage settle in the bed of the River Cooum, and form layer upon layer of horrible deposit, while the fluid portion emits the stench which has gained for the river its unenviable notoriety. As the hot weather increases, the river gains in potency until the noxious exhalations are apparent at a considerable distance.

The nuisance and inconvenience which must result for the numerous dwellers upon or near the banks must be very great; many large buildings, such as Government House, the Government Office, the Senate House, and the Penitentiary, are near it; whilst the effects on the inmates of the General Hospital and the Women's and Children's Hospital are matters for grave consideration. The river, also, breeds myriads of organisms, and is credited with producing the plague of mosquitoes which at times infests Madras. In this cesspool of stagnant filth men may be seen every day fishing, and doubtless the results of their labors are vend for human consumption. Thus the river in its present condition is a standing menace to the health of the inhabitants of Madras during the time it remains a motionless pool in the centre of the town; even when tidal it is a source of great danger under the present conditions, as the decomposed and decomposing deposits on the bed of the river are disturbed by the action of the tidal waters, and thus permitted to freely throw off obnoxious gases. The greater part of this sediment

would doubtless be removed when the river is in flood and flowing freely outwards to the sea, but this may only occur for two or three months in each year, the remaining nine or ten months the mouth of the river is blocked by the bar, and the matters held in suspension must be deposited.

No scheme of drainage for the town of Madras will be in the remotest degree satisfactory unless it provides for the total elimination of all sewage matter from the River Cooum.

Although the report was written in the middle of 1893, and in October 1895 the Army Sanitary Commission stated that Madras had arrived at a critical point in its sanitary history, it was not until last March that the Madras Government sanctioned the long-contemplated drainage scheme, but the main part thereof was postponed pending arrangements between the Government and the Municipality.

The deaths from dysentery and diarrhoea were 2,392, a decrease of 316, or 11.66 per cent. under 1893.

The principal water supply of the town is received from the Red Hills tank, arriving at the town after flowing through about six miles of more or less inhabited area. The distribution is on the "constant system," but pressure is insufficient, and at times the pipes at certain points are empty, irrespective of the whole town supply being turned off for two hours weekly. Flushing pipes dip directly over and into drains, certain mains pass through streets, pipes to fountains pass beneath permeable gutters, and run close to old underground permeable drains; contamination by aspiration of air on fluids is therefore possible during temporary cessations of flow.

Another source of water-supply—the "town wells"—and that used by the British troops is derived from the subsoil flow in a belt of sand within the inhabited area of the town, and in former days yielded a fairly pure supply, but the wells are within the subsoil flow of the site of a sewage farm that is not under-drained, the farm being made of rubbish deposits that must contain tons of faecal matter. It is not to be wondered at that the water is now pronounced chemically bad. Typhoid fever has been frequent and coincident with a general fall of the subsoil water level of the town site, and the source must therefore be regarded with suspicion, though no direct proof of specific contamination has been forthcoming. The conservancy arrangements of the municipality are bad in the extreme, both staff and plant being below actual requirements. Many of the old tanks of the town have been in former days, and up to the present time are, filled with town rubbish, and, therefore—in the absence of a complete night-soil system—with much excreta. Without entering into further details, it stands to reason that the subsoil of the town is peculiarly and unusually contaminated with organic matter, and is unfit for use as a water-collecting area.

No substantial improvement was produced during the year in the sanitation of Madras, but £40,000 was borrowed for expenditure upon the improvement and extension of the water supply. A scheme for the purification of the Cooum was approved by Government, and estimates for carrying it out were under preparation. The drainage scheme prepared by Mr. COVINGS was also under consideration, but the Government were of opinion that the cost of its execution, which would necessitate an increase of 62 per cent. in the taxation of the city, was prohibitive, and that native habits and the conditions existing in the city would render the closed connection with houses proposed in it unworkable, and a source of danger rather than of benefit to the inhabitants. A modification of the scheme has since been proposed by a committee of the Commissioners and was under the consideration of the Government. Estimates were also drawn up for carrying out Mr. COVINGS' scheme of water supply. In addition to the above proposals for the more satisfactory disposal of the rubbish of the city were being matured, and other improvements were in contemplation. The execution of these schemes of improvement is expected to produce a real advance in the sanitary condition of the city.

The municipality was carefully inspected during the year. The highly unhealthy condition of the city having attracted the attention of the Madras Government, in 1890, a special committee was appointed to advise as to the nature of the urgent sanitary improvements, in connection with drainage and water supply, that were considered necessary. Rough schemes were formulated, and the Government, on the advice of the committee, employed a European expert sanitary engineer to advise and estimate the complete scheme—the Public Health Engineer.

(To be cont. next.)

VITAL STATISTICS OF CALCUTTA.

Statement of Deaths from Principal Diseases in Calcutta during the week ending 14th May to the 4th June 1902.

Week ending	Cholera.	Small-pox.	Fever.	Bowel complaints.	Also other diseases.	Total.	Total population, according to the census of 1891.	Ratio per 1,000 of population per annum.
14th May	24	4	92	57	179	356	6,81,540	27.2
21st May	17	1	101	62	217	398	..	30.4
28th May	15	2	86	62	168	333	...	25.4
4th June	7	3	79	67	179	335	...	25.6

Current Medical Literature.

MEDICINE.

Varieties of Diabetes Mellitus.

DR. LEPINE shows that clinical observation distinguishes between certain varieties of diabetes mellitus. In the nervous variety the glycosuria is often quite moderate, and may even disappear, leaving behind a simple polyuria. The type developed under the influence of gout in arthritic individuals is associated with an intermittent but abundant glycosuria, and is comparatively benign. Certain diseases of the pancreas, such as calculi of Wirsung's canal and sclerosis of the whole parenchyma, may be followed by a rapid and dangerous diabetes. There are other varieties difficult to classify. Each case is constituted by several pathogenic elements of varying importance. Hyperglycæmia may be caused by lack of the physical storing of glycogen by the hepatic cells (azocyemia) and this condition of the cells may be caused by lesions or irritation of the nervous system, various poisons, ablation of the pancreas, etc. Another cause may lie in the excess of primary proteolysis and in glyco-genesis without glycogen. It is a positive fact that in many cases of diabetes there is exaggerated destruction of nitrogen, and some diabetic patients excrete large quantities of sugar after the ingestion of much meat. There is ample justification of the assumption that sugar produced in the organism may be derived directly from albuminoid substances. In certain forms of diabetes the sugar may be lacking. It may disappear either by transformation into fat or by oxidation. The inadequacy of one or other of these two processes may constitute a pathogenic element of diabetes. There may also be a reduction in the amount of the glycolytic ferment, and the renal element must not be overlooked. In pancreatic diabetes there is azocyemia, diminution of the glycolytic ferment, diminished formation of fat, diminished production of sugar. In the nervous variety there is azocyemia, exaggerated hepatic glyco-genesis, and diminution of glycolytic ferment. The theory of multiple factors explains the infinite varieties of the disease.—*Sem. Med.*

Splenic Tumor in Rachitis.

DR. VON STABOK says, that in one hundred cases of rachitis the diagnosis of splenic enlargement was made sixty-eight times. The situation of the tumor is the same as in the adult. There is no ground for the belief that the spleen is relatively larger during the first year of life than in the later years of childhood, yet during the first year the spleen shows an extraordinary tendency to enlarge under pathological conditions. The splenic enlargement, in the cases of rachitis examined, was generally medium. There is no constant relation between the severity of rachitic bone changes and the amount of enlargement of the spleen: the latter is more constantly governed by the severity of the accompanying anemia. Autopsies on rachitic children (where other causes of splenic enlargement, e.g., infectious diseases, could be excluded) showed a splenic tumor in over fifty per cent. of the cases.

The tumor was more generally found in those presenting marked rachitic bone alterations, yet even if the latter be very severe the enlargement may not exist. The splenic tumor, either macroscopically or microscopically, shows nothing characteristic. The writer concludes that tumefaction of the spleen can hardly be considered a symptom of rachitis in children, and that it is caused by the same unknown noxious product that produces the rachitis.—*N. Y. Med. Jour.*

Differential Diagnosis between Gastritis and Cancer of the Stomach.

CHAUFFARD recognizing the difficulty in differentiating hypopeptic gastritis from cancer of the stomach, says that variation in weight of the patient is a sign of great value. As a general rule, if a cancerous patient is put upon suitable diet and is given a great deal of rest, his weight will slightly increase, perhaps to the extent of three or four pounds. Such increase in weight is invariably followed by a progressive loss which continues without interruption until the patient is emaciated. A dyspeptic patient, on the other hand, will continue, under suitable treatment, to gain weight until a maximum point is reached, at which the weight is constantly maintained—a point which may be fifteen or twenty, or even thirty pounds in excess of the weight at the beginning of the treatment.—*Med. News*

Pyretic Drugs.

IN his Croonian lectures, Dr. W. HALE WHITE stated that there are many pyretic drugs. Thus strychnine and caffeine both raise the temperature a little and large doses of quinine cause considerable elevation of temperature, which may suddenly rise to 104°F. in belladonna poisoning; but the rise produced by 5 tetrahydronaphthylamine in the pulse, respiration and temperature so resembles in extent and rapidity that caused by injuries to corpus striatum that it is probable that in this drug we have an agent that stimulates the thermogenetic centre without exciting the motor function of muscle; or, in other words, this drug, acting on the muscles through the central nervous system, is capable of producing a rise of 8° to 9.9°F. in one hour, and that if it is to be used as fever remedy, great caution is required on account of its marked effect on the heart.—*Brit. Med. Jour.*

Chronic Glycosuria.

IN a paper presented to the Académie de Médecine, WORMS who has a wide clinical experience of this disease, advises patients to determine each his own diet and take plenty of out-door exercise if they wish to ensure longevity. He examined the urine of 100 brain workers, who led sedentary lives and found considerable quantities of sugar in 7 of them; whereas among 607 artisans and laborers sugar was not found in one. After excluding the hepatic cases he classifies diabetes as:—(1) Those who have large proportions of sugar, but easily reducible. (2) Those whose sugar is not reducible; and (3) those in whom the sugar altogether ceases, but reappears after a long interval—sometimes as long as 12 months generally after some violent emotion, and this is particularly the case in gouty subjects.—*Cal. Jour. of Med.*

SURGERY.

Transplantation of Skin, evenness without Pedicle from one part of the Body to another and from one Patient to another.

HAVING, some years ago, to operate on a woman for psoas, Dr. C. HELL TAYLOR inadvertently excised rather more than he wanted of the upper lid, but finding it impracticable to transplant a piece of skin with pedicle from the immediate neighbourhood, he replaced the apparently dead eyelid which took kindly to its old quarters and the shrinkage due to its temporary denude (transplanted skin shrinks to nearly $\frac{1}{2}$ of its original size) sufficed to restore the normal position of the lid. Since this he has frequently transplanted skin from one part of the body to another, and from one patient to another. On one occasion he cured extensive symblepharon by transplanting a large piece of skin on to the surface of the eyelid itself and in another case where the facial tissues were so completely destroyed by burn as to make it impossible to find healthy tissue in the neighbourhood of the orbit, he restored an eyelid by a piece of skin taken from the forearm. The points necessary to success are (1) clear away subcutaneous tissue, (2) closely approximate the edges, (3) apply pressure and (4) keep the flap warm.—*Lancet*.

Lumbar Nephropexy without Suturing.

SMITH, who strongly objects to the practice of incising and detaching the fibrous capsule and thus permanently and seriously injuring the kidney, relies on extensive excision of the adipose capsule in the fixation of movable kidney and altogether dispensing with sutures, trusts exclusively to (1) extensive removal of the perirenal fat, (2) scarification of the fibrous capsule, (3) direct temporary support of the kidney by a strip of iodoform gauze, (4) plugging the wound with gauze, and (5) prolonged rest on the back with (6) localised compression of the front of the abdomen.—*Jour. Amer. Med. Assoc.*

Spontaneous Straightening of Bickety Curvatures of the Leg.

FROM a study of a large number of cases at the Tubingen Clinic, KAMPE concludes: (1) The greater number of all cases of bickety curvatures of the legs undergo spontaneous cure. Of the author's cases, all severe, seventy-five per cent. were cured, 16.8 per cent. improved, in only 9.7 per cent. was there no improvement of the deformity. (2) The process of spontaneous straightening lasts usually from two to four years. If the curvatures began in the first or second year of life the legs are quite straight by the fourth or fifth. (3) If the curvatures are unchanged by the sixth year, spontaneous cure does not take place at all. There are always cases of most severe general rickets. (4) The chief aim in treatment is to improve the general health so as to strengthen the muscles. In KAMPE's experience, as soon as the disease is past the acute stage, being about on the legs is not detrimental, but, on the contrary, helps the cure. Orthopaedic treatment by plaster-of-paris, splints, etc., is not necessary. Osteotomy is indicated only when the curvatures persist after the sixth year.—*Canad. Prac.*

Operative Surgery of Gastric Ulcer.

EXAMINATION gives the indications for surgical interference in gastric ulcer: (1) In perforation it is absolutely necessary as early as possible before the perforation, and to wash out the abdomen. Since 1884 the mortality after operation has fallen to 53.94 per cent., and without operation the condition is almost invariably fatal. (2) For stric-

ture of the pylorus. In this condition it is hard to distinguish obstruction from swelling of the tissues round the ulcer or from pyloric spasm from pyloric stenosis. For the latter there are three possible operations: (a) Resection of the pylorus; (b) gastro-enterostomy; (c) pyloroplasty. Of these the first is the most dangerous, and has no advantages over the others, unless the ulcer can be excised with the pylorus. Pyloroplasty is not applicable if the ulcer extends to the pylorus, or where the pylorus is adherent, and its walls have lost their softness. When there is choice between the second and third methods, MIXTER prefers pyloroplasty. (3) Operation may be required for adhesions or abscesses in connection with the ulcer. These are mostly very hard to diagnose, but it must be remembered that in some cases of persistent pain exploratory laparotomy is justified. (4) For hæmatemesis. Since sudden death is the exception, and many cases recover with medical treatment, the propriety of operation is still doubtful. HARTMAN's 12 cases gave 8 deaths and 4 recoveries. The author believes the chief point to be the quantity of blood lost. For violent hæmorrhage laparotomy has almost always failed. Sometimes the infiltration of the surrounding tissues has rendered excision of the ulcer or ligaturing the bleeding vessel impossible. Often the bleeding comes from a branch of the splenic artery, whose territory is very difficult to reach, and sometimes the ulcer has been too small to be found. For slighter hæmorrhages which become dangerous through repetition operation may be successful; usually pyloroplasty or more often gastro-enterostomy have been performed in such cases with a view to procuring rest of the stomach, and consequently of the ulcer and its healing. (5) This last consideration has led some to propose gastro-enterostomy for cases of uncomplicated gastric ulcer. The general death-rate for all cases of gastric ulcer is 25 to 30 per cent., for gastro-enterostomy only 16.2 per cent., and therefore the operation has less danger than the disease. Another advantage of not waiting for complications is that the patient is in better health. At any rate cases which do not improve with medical treatment in a reasonable time should be treated surgically.—*Brit. Med. Jour.*

A Story with a Moral.

DR. FREDERICK HOLME WIGGIN said that the great mortality following operations for intestinal obstruction was due, in his opinion, to the delay in operating. The usual history was that the attending physician had purged the patient freely with saline, and had lost very valuable time before calling in a surgeon. He referred to a case in which the patient had refused operation and the friends had besought him to give morphine. He had given some dose, but, finding no amelioration of the symptoms, he had positively refused to continue its administration. Finally consent was obtained to an operation, and when it was performed it was evident, from the beginning gangrene of the parts, that had he yielded to their entreaties and continued the morphine, death would have been the result. It should be remembered that occlusion of the large intestine might exist for ten days or two weeks without any marked symptoms, except vomiting. In chronic cases there was often a history of a blow or some injury which would aid one in locating the seat of the trouble. If there was a history of constipation, and rectal examination and rectal enema gave a negative result, there was reason for believing that the case was one of intestinal obstruction. The general practitioner often made the diagnosis of intestinal obstruction, but delayed in sending for a surgeon until he had determined the particular cause of the obstruction.—*N. Y. Med. Jour.*

MR. GLADSTONE'S DEATH. THE PASSING OF A GREAT MAN.

SAYS THE LANCET:—"We do not intend to give any detailed obituary notice of the great man who has just passed from among us. Our readers have before them the ample story of Mr. GLADSTONE's grand career in all the daily papers and in most cases it will be the province of such papers to discuss political matters upon which we are unable as a medical journal to take a view. But at the same time we desire to register our feelings of profound admiration for the dead statesman's lofty ideals, unrivalled intellectual powers, and wonderfully sweet and buoyant temperament. In Mr. GLADSTONE a lowly trust in God was joined to the highest aspirations for the good of humanity, and the sense of the loss which the nation feels itself to have sustained by his death cannot be adequately expressed. Medicine, its science and practice, falls as a part of the social scheme beneath the domination of a real national leader, so that in common with the rest of the community we rejoice when our leader is a good man as well as a great one, and while rejoicing benefit. It is unnecessary to point to special acts or speeches that we may prove Mr. GLADSTONE to have been the friend of those who follow our calling, though to do so would be easy. Being the man that he was it was inevitable that he should sympathise with us and with all who work to help the weak. For Mr. GLADSTONE was exactly 'the man of mercy' whom the Son of SIRACH has described, as he was and is, also, one 'whose glory shall not be blotted out' but 'whose name liveth to all generations.'"

The President of the General Medical Council said a suggestion had been made to him that the Council should join other public bodies in recording their sense of the loss which had befallen the nation through the death of Mr. GLADSTONE. He therefore moved the following resolution which was carried unanimously by the Council in Session:—

"That this Council desires to place on record its sense of the grievous loss which has befallen the nation by the death of the Right Hon. W. E. GLADSTONE, whose interest in the profession of medicine was ever warm and sympathetic, and under whose administration the Medical Act of 1896 was passed into law. The Council further requests the President to transmit to the widow and family of the deceased statesman a suitable expression of the Council's heartfelt participation in the national sorrow."

ABSCESSES OF THE LIVER.

THE two following cases of liver abscess treated by free incision are related by M. RICHELOT:—

The first case was that of a young man aged 23 years, who had returned from a two years' residence in Saigon and Tonkin, where he had suffered from dysentery. The disease had been diagnosed as pulmonary tuberculosis with localised empyema. M. LAFONCADA (of Bagonne, under whose treatment he came) diagnosed liver abscess following dysentery, and according to LANNELONGUE'S method resected the lower margin of thorax, which enabled him to freely incise the liver abscess. The patient died on the 22nd day.

In the second case, M. LAFONCADA opened the abscess by transpleural laparotomy, recovery followed without incident.

M. RICHELOT related a case of his own, in a man who had returned to France 10 years previously after having served in the Tonkin Campaign, in the intervening time he had only suffered from occasional attacks of fever, the liver extended to a considerable distance below the arch of the ribs, and in this situation laparotomy was performed and about 350 grammes of pus evacuated from a liver abscess. Three months later he incised a second abscess which presented below the xiphoid cartilage, and shortly afterwards a third abscess appearing,

it was also opened. Complete cure followed. The pus from the third abscess was sterile, that from the other two was not tested.

A DEBT COLLECTOR ON THE SYMPTOMS OF PLAGUE.

A GENTLEMAN, who signs himself ALEX. J. AGASS, Superintendent, Public Debt Office, Bank of Bombay, in a letter to the *Englishman* under the above heading, is kind enough to treat us to some very original views of his own as to the true nature and pathology of plague; the ideas will no doubt interest as well as afford considerable amusement to our readers. "This so-called plague," we are told, is nothing else but a most virulent attack of "malaria," and the bacillus which has been discovered is no other than the "bacillus malarie" which has not been known in India before. It is something to be thankful for that the dreadful "bacillus malarie" has not previously visited our shores, but whence all the malarial fevers with which we are so well acquainted!

"The microbe," we are informed, "appears to have vegetable of a group Schizomycetes, and of a family near Algae, it is so small that it is difficult to imagine its size."

Mr. AGASS appears to be an individual of the group mediocres, of a family near maddies, but his errors are so enormous that it is difficult to imagine their size.

Regarding symptoms he says:—"The skin only in very exceptional cases has shown black patches, and scarcely can you find the whole body blackened." The meaning of this charming sample of English "as she is writ" in Hindostan we leave to the discernment of our readers, while we wonder at finding it admitted to the columns of the *Englishman*.

PROFESSIONAL SECRETS.

THE *Medical Times and Hospital Gazette* says:—"The question of professional secrecy is one which perpetually recurs in very different forms. There can be no doubt of the absolute necessity for inviolable secrecy as to matters made known to a doctor by a patient in the course of consultation. One cannot, of course, severely blame a doctor who deviates from his plain duty in this respect owing to fear of threats by those who administer the law; but at the same time we must admire those who decline at all risks to betray confidence reposed in them. To do as some suggest ought to be done, namely to give information to the police of every crime (or what the law calls crime), which comes under medical notice professionally, would be as wrong in principle, as it would be ruinous in practice. There are, however, cases in which secrecy would be sure to endanger either the patient or others, and here the doctor must, of course, undertake the responsibility attached of necessity to the information acquired. If a patient betrays to a doctor plain symptoms of homicidal or suicidal tendencies, it is an obvious duty to take suitable steps to guard against consequences, and no blame can be attached to a doctor who finds it desirable to convey the information to those who ought to have it. Again, if a patient is dangerously infective, a doctor, in the event of the patient refusing to take proper precaution for the safety of others, might under some circumstances be justified in warning those exposed to risk. The exceptions, however, should be very few. The fixed rule is absolute secrecy!"

ANTIRABIC INOCULATIONS.

SAYS the *British Medical Journal*:—"The *Annales de l'Institut Pasteur* contains a brief summary of the work for the year 1897. The number of persons bitten by rabid animals and treated at the Institute was 1,551, and of these 8 died. If 2 cases in which death occurred before treatment could take effect are excluded, the 6 deaths give a total mortality of 0.39 per cent. The cases are classified under three

cases of those bitten by dogs proved by injection experiments to have been rabid. 2. Cases bitten by animals certified in kind by veterinary surgeons. 3. Cases in which the wounds are suspected only. The mortality in the first of these classes is always higher than in the other two. It never, however, exceeds 1 per cent., and during the year in question only reached 0.7 per cent. Bites on the face and head were most fatal, the hands and limbs coming next in order of danger. Of the fatal cases one died six months after treatment, most of the others at intervals of a few weeks only. It is interesting to note that in 3 of the fatal cases the rabid dogs which inflicted the wounds were known to have bitten other persons who have not subsequently developed any symptoms of rabies. One of these persons had undergone a course of treatment at the Institute, the other had not. Of the 1,531 persons treated in Paris 175 were foreigners; the countries contributing the greatest number being—England, 55; India, 50; and Switzerland, 34.

LAND AND FLOATING HOSPITALS AT RANGOON.

ARRANGEMENTS have been made by the Rangoon Municipality to procure a loan of a river flat from the Irrawaddy Flotilla Company. This flat will be properly fitted up to meet the requirements of a hospital, and will be anchored in the river. The lower deck of the flat is being lime-washed from stem to stern, while the upper one will be similarly treated. The top portion has been matted in and equipped with other necessary arrangements. Lying alongside this flat is another but smaller flat-bottomed boat, which will be utilised as a disinfecting apparatus. To answer this purpose it has been equipped at one end with a machine and large boiler for generating steam, which will escape through a number of pipes into three reservoirs specially fitted up for facilitating the work of disinfection. At the opposite end two cells have been built into which a pair of trolleys will be run from the reservoirs with the infected linen, which will undergo a further process of disinfection under steam in an enclosed cell. The work of completion is being rapidly pushed.

It has been decided to erect a portion of the new General Hospital for Rangoon in order to provide sufficient accommodation for European and paying patients, to alter the present hospital, to build an infectious diseases hospital for Europeans, and to convert the present infectious diseases wards into wards for females suffering from contagious diseases, at a total cost of four lakhs, excluding the cost of the site for the new buildings. The Provincial and Port revenues pay one-fifth, and the Rangoon Municipality four-fifths of the expenditure of three lakhs and fifty thousand on the contagious diseases hospital under consideration, but the Municipal Committee thinks that if the present vaccination law is amended by making adult vaccination and re-vaccination compulsory, this expenditure will be necessary.

The steamer *Telfer* is being fitted up in the Rangoon river as a hospital, while on the bank will be a segregation camp. The steamer will serve as a hospital for the whole town. A hospital will also be built at Theinbyn, where the present infectious diseases hospital is. This will be for the Eastern half of the town, and, if necessary, there will be a segregation camp on the newly-reclaimed ground. A meeting of the medical men in town will be held shortly to discuss matters. Two trained nurses have been sent for from England.

ENTERIC FEVER AMONG THE TROOPS IN INDIA.

SAIR'S The Lancet:—"General BOWEN asked the Secretary of State for India whether the Government of India had arrived at any conclusion regarding the cause of the great increase in enteric fever among European troops in India;

whether the investigations made were concluded; and whether it was proposed to adopt any special measures to diminish the spread of the disease. Lord GOWAN HAMILTON replied: "The definite conclusion has been arrived at as to the cause of the disease, it enters fever among British troops in India, and the investigations on this subject are still progressing. Several medical officers having been specially detailed for this duty. Generally the measures taken to check the spread of the disease are the improvement of the water-supply, the provision of pure milk and butter, and improved sanitation of camp, cantonments and barracks. One cantonment, Daghada, where there have been serious outbreaks of enteric fever, has been completely evacuated for a year, pending the installation of an improved water-supply and the disinfection of the barracks and their vicinity."

SURGEON-CAPTAIN C. DALTON, A. M. S.

ANOTHER case of distinguished heroism, says the *British Medical Journal*, is thus alluded to in the *Army and Navy Gazette* of 7th May—

"When Lieutenant CRAIG-BROWN, 1st Battalion, West India Regiment, was severely wounded in the fighting recently in Lagos, Surgeon-Captain C. DALTON, A. M. S., dressed his wounds on the spot where he was shot down amidst a hail of fire. A carrier, who was by his side at the time, was shot dead. Another thrilling act was performed by the same officer together with Sergeant-Major M'KILLOP. It was found, when the company got into safe quarters, that a wounded West India native had been left behind. The man was badly wounded. Captain DALTON and M'KILLOP at once went back, a distance of 500 yards, into the enemy's quarters under fire, and brought the poor fellow back. Unfortunately the man, whose name was BARRETT, died. The act was none the less one of great gallantry, and, as a correspondent puts it, 'at time when some would try to make out that the army doctor is simply a civilian hanger-on to the army, it is right that all honorable men among combatant officers should rise in revolt against such a libel and injustice, which can in the long run only produce its proper result.'"

THE GENERAL HOSPITAL AND DR. PILGRIM.

SURGEON-CAPTAIN HERBERT WILSON PILGRIM, I. M. S., is M.R.C.S. Eng., L.S.A. Lond. (1884), and M.B. Lond., (1885). He hails from the West Indies, and was medically educated in the University of Edinburgh and in University College, London. He joined the Indian Medical Service in 1886, and has therewith 13 years' service. He was appointed Junior Resident Surgeon of the Presidency General Hospital in June 1890, and was promoted to First Resident Surgeon on the 1st of April 1896 on a salary of Rs. 900 per mensem. His present position, as Superintendent of the hospital, just doubles his salary. There is not another officer in the Indian Medical Service of his rank who is in receipt of a salary of Rs. 1,800 per mensem. Dr. PILGRIM has had 8 years' practical experience of the working of the Calcutta General Hospital, and his merit and special experiences are to be accorded their just reward. Dr. PILGRIM certainly deserves his promotion. There can be no question of a doubt however that from a service point of view, the selection of a Junior surgeon for so important an administrative office, will evoke the severest criticism, as in making such a selection the Government has over-riden the custom rules and regulations of the service.

TREATMENT OF STYPTIC IN THE ARMY BY INTRAMUSCULAR INJECTIONS OF MERCURY.

SURGEON-CAPTAIN F. F. W. FORSTER, R. M. F. writes to the *British Medical Journal*:—"I think

the present state of the art in Europe, and the progress for the future, and the importance of the treatment of the disease to the notice of the public. It has been attended by very many medical men of this country, and with the greatest benefit to the public and the State. The reason why it is not more extensively used are (1) the difficulty of procuring a suitable alloy; (2) the necessity of the use of impure mercury; (3) the large size of the crown. I have not found the vulcanite alloy as good in this country; the barrel works loose and the needles separate from the vulcanite. I now use an ordinary syringe made by WILKINS in which the needles screw on. I make the crown from AMALGAM chemically pure dental mercury, and never inject more than 5 minims at a time. With the man standing, I insert the needle high up near the crest of the ilium, and push it downwards and forwards. I have given about 800 injections and have never had an abscess. The men are able to perform all their duties and even to ride.

A CHINESE CHRISTIAN PHYSICIAN IN LONDON.

THE *Friend of China* says:—"An interesting incident of the year's work has been the visit of Dr. TAO YUNG-KWAI, physician to the Special Envoy who represented the Emperor of China at the Diamond Jubilee of our beloved Queen. Dr. TAO, who is on the staff of the Methodist Episcopal Missionary College in Peking, was entertained by the Society at an informal afternoon gathering in Westminster Town Hall, when an address of welcome was presented to him. He feelingly acknowledged the efforts made by British Christians to put an end to this great curse that afflicts his country. The address was afterwards engrossed and illuminated and forwarded to Dr. TAO, at Peking, and we have received from him a cordial acknowledgment, stating that he is bringing the matter before the Christian churches in Peking. Amongst those present at the reception was Dr. WALLACE, of Calcutta, Editor of the *Indian Medical Record*, which has subjected the Report of Sir WILLIAM ROBERT, as Medical member of the Royal Commission, to the incisive criticism referred to in our last report. Dr. WALLACE confirmed the testimony of his Chinese confidante as to the evil effects of the opium habit."

ANGLO-INDIAN CLAIMS AND ASPIRATIONS.

SURGEON-COLONEL KENNETH MACLEOD, M.D., F.R.C.S., writes:—"I observe from Indian papers, recently received, that the agitation for obtaining encouragement and recognition by the State for members of the Anglo-Indian or domiciled British community in India is being actively carried on. Nothing but good can come of representing the numbers, the importance, the services, the capacities, the loyalty of that community in this country, (England) and for the purposes of such representation strong and wide associations are needed. I see that a point has been made of the disabilities of the communities, as well as of their merits and capabilities; and accusations have been cast on the Government of India that these disabilities are the creation, not of circumstances but of arbitrary administrative initiative, actuated by racial prejudice and unfounded disparagement of a people peculiarly placed, who have not been able sufficiently to assert themselves under the conditions of their existence in India. I am inclined to think that this point is sound and that the circumstances are more to blame for the disabilities than the authorities."

PRESENTATIONS TO SIR WILLIAM STOKES, F.R.C.S.

AN interesting ceremony, says the *British Medical Journal*, took place in the Royal College of Surgeons, Dublin, on Saturday, 27th May, when an address and some valuable plate were presented to Sir WILLIAM STOKES on the completion of his twenty-fifth year of office as Professor of Surgery in the School. The subscribers comprised thirty-one old and present

members of the college, and included Lord Lister, Sir THOMAS SWAN, and Professor OGDON, of Aberdeen, who was able to be present. The chief gift was accepted by Sir WILLIAM THOMSON, President of the College, who made the presentation, and speeches were delivered by Sir CHARLES CAMERON, Sir GEORGE DUFFY, and Mr. WYLLIE. Sir WILLIAM STOKES made a most effective reply, marked as it was by great eloquence; and he made touching allusion to the gift to Lady STOKES which accompanied the presentation. In the evening the Professors entertained their colleagues at dinner. Sir CHARLES CAMERON was in the chair, and there were also present Sir W. THOMSON, F.R.C.S., Sir GEORGE DUFFY, Professor OGDON, Dr. JAMES LIFTON, Professor FRANK, Mr. MYLES, Dr. J. W. MOORE, Mr. HEUSTON, and many others.

THE TITLE OF "DR."

THE *British Medical Journal* says:—"At Newcastle, THOMAS PAINE HETHERINGTON, styling himself 'Dr.' but not on the *Medical Register* or holding any registrable qualification, was charged before the magistrate under the 40th Section of the Medical Act, 1858, with wilfully and falsely pretending to be a doctor of medicine. It was stated that the defendant was a dentist and a doctor of medicine of the United States. The case was however practically undefended, no evidence being called on behalf of the defendant, and who in the absence of proof that he held any medical qualification, was fined £20 and costs. The prosecution was instituted by the Medical Defence Union."

"At the Newcastle County Court, recently, before Judge GREENWELL and a jury, THOMAS PAINE HETHERINGTON (who, as above stated, was fined £20 at the police-court for illegally using the title of 'Dr.') was sued by the Society of Apothecaries for having practised without having a medical diploma. The jury found for the Society, and judgment was given against the defendant for the full amount claimed, £20 and costs."

THE "JOURNAL OF TROPICAL MEDICINE."

SAYS *The Lancet*:—"It is proposed, if enough support can be obtained for the scheme, to publish in London a monthly journal dealing with the diseases of warm climates, to be devoted to the publication of papers on tropical diseases and to the discussion of subjects scientific and practical affecting the interests of medical men in tropical and subtropical climates. The annual subscription, including postage, is to be 17s. We wish the promoters success in their new venture. They deserve it, for there is no country which has such a large interest in the tropics and the diseases common to them as our own. Any communication addressed to the Editors, *Journal of Tropical Medicine*, Messrs. JOHN BALE, SOHN and DANKLEIN, 85 to 89, Great Titchfield-street, London, W., will receive attention. The editors are Mr. JAMES CARTER and Dr. W. J. SIMPSON."

CLIMATE AND MORALS.

A CURIOUS investigation has been undertaken by the officers of the weather bureau in the United States. Colonel WILLIS MOORE originated the investigation, believing that there is a close connection between the condition of the atmosphere and the physical and moral well-being of the people. The results of these investigations are as follows:—Taking in the whole country during January, February, and March, there were in round numbers 1,800 suicides reported in the United States; while in July, August, and September there were 1,400. In the same period there were 1,700 murders in the cold term, as compared with 1,200 in the three hot months. There were 50 persons hanged or lynched in the three cold months, and 115 hanged or lynched in the three hot

months. The investigation is said to have been instituted with the idea of issuing in the near future warning of the approaches of crime waves.

THE PLAGUE IN CALCUTTA. NO NEW DISEASE.

Cases of malignant fever of a distinctly fatal type and officially declared to be "sporadic plague," continue to be ferreted out of the dirtiest and most unhealthy plague spots in the city. From the date of the official announcement of this disorder as plague, 106 suspected cases have been reported and 61 have turned out fatally up to the 18th instant. There is considerable doubt as to all of these cases being of one and the same kind, or even one of the three different types of "plague," so that, as a matter of fact, while dysentery, cholera and famine-stricken people in *articulo mortis*, have been pronounced as cases of "sporadic plague," there is infinite difficulty in correctly stating, as a matter of indispensible truth, how many of these cases are real and how many are spurious. For all this, however, the city is condemned as a *plague infected* locality, and its commercial prosperity is doomed. We say doomed, because house-to-house visitation, if commenced fifty years ago, would have produced similar results in the discovery of certain types of malignant fever; and if the same process is continued for the next half century, there will be no dearth of discovery of similar cases, for as long as such festering plague spots as are at present to be found, exist all over Calcutta, so long will our unfortunate experiences of "sporadic plague" be monotonously unchanging. These are stern and solemn facts, and they can be borne out by the experience of the oldest living medical practitioners of the city and by the writing of still older though long departed ones.

INDIAN MEDICAL REGISTRATION IN PARLIAMENT.

It must be extremely gratifying to the Indian Medical Association to find that its laudable efforts to bring about the enactment of a Medical Registration Act for India are rapidly moving towards success. The fact that this important measure was considered by the General Medical Council of Great Britain at its last session, though with no very definite results, is still satisfactory. That its further efforts have resulted in a question being asked in Parliament, is another step in advance, and ought to encourage India and the local profession with the hope that the goal is approaching and victory is nigh. We quote the following paragraph from the *Lancet* of the 28th May:—

"Sir WALTER FOTHER, M.D., M.P., asked the Secretary of State for India on Tuesday, the 17th May 1891, whether he was aware that at present uneducated and unqualified persons have as much right to practise medicine in India as fully qualified practitioners; and whether in view of the danger to which the Indian people are thereby exposed, he would consider the advisability of instituting a system of registration for medical practitioners similar to that which exists in Great Britain and Ireland. Lord GEORGE HAMILTON replied: The answer to the first branch of the question is in the affirmative and that to the second branch in the negative. It would be, in my judgment, impossible in the present condition of India to prevent the people of that country from resorting to native practitioners, even though they may be regarded by Europeans as not fully educated or qualified for the work they undertake."

HAVE THE PUBLIC FAITH IN OFFICIAL COMMITTEES?

In answer to the above question, Reuter telegraphs:—"The Governor of the Bank of England, in a letter to Lord GEORGE HAMILTON, says that the majority of the Indian Currency Committee consists of officials, and as now constituted, the Committee fails to command the confidence of the city."

In spite of the fact that under the new "Sedition Act," anything "from winking one's eye to damning the Viceroy" may be construed into sedition, we desire to say in answer to the question that heads this comment, that the public have no

faith in the Bengal Plague Commission, the majority of whom are officials, who, as a matter of fact, are sending their heels in Darjeeling, and whose toll and thought in connection with plague matters in Calcutta, may be summed up in a little word of three letters—NIL. Where is the Bengal Plague Commission? Echo answers where?

ROYAL COLLEGE OF SURGEONS IN IRELAND.

SAYS the *British Medical Journal*:—"The election of President, Vice-President, and Council will take place on the first Monday of June. Mr. R. L. SWAN, Surgeon to Steevens's Hospital, will succeed to the presidential chair, which has now been occupied for two years by Sir WILLIAM THOMSON. For the vice-presidency, which becomes vacant by Mr. SWAN's promotion, there are two candidates, Dr. C. B. BALL, Regius Professor of Surgery, Trinity College, and Mr. THOMAS MYLES, Surgeon to the Richmond Hospital. It is believed that the contest will be very close. For the Council Mr. H. G. OROLY, Mr. M'CAUSLAND, Mr. ROBERT H. WOODS (who retires from the secretaryship to Council), Dr. CRAWF, Mr. CHANCE, and Mr. J. HARRISON SCOTT will be candidates."

WHERE LIFE IS LONGEST.

OF all the countries in the world, says the *Philadelphia Medical Journal*, it is Servia which contains the most centenarians. In this little country, which has less than 1,800,000 inhabitants, there are actually 575 persons whose age exceeds 100 years. Ireland comes next in the list with 573, but then her population is very much larger than that of Servia. Spain has 401 out of a population of 17,000,000, and France counts 218 among her 88,000,000 inhabitants. England, Scotland and Wales can only muster 192 between them, and Germany with her enormous population of 55,000,000, has but 78. Norway has 23 out of 2,500,000 inhabitants and Sweden a population of nearly 5,000,000, and only 20 centenarians. Denmark has but 2, and in little Switzerland there is not a single person whose years number five score.

CHLOROFORM SYNCOPE RESTORED BY ARTIFICIAL RESPIRATION AND NITRITE OF AMYL.

In the *Lancet* of 19th September 1891, page 665, EDWARD RICE, M.D. London, of Oxford, reports a case of chloroform syncope restored by nitrite of amyl and artificial respiration. The subject was a woman, 40 years old, and was chloroformed through a Junker's inhaler, for the purpose of having a growth excised. Three drachms of chloroform were inhaled and syncope ensued. Dr. RICE insists that the pulse failed first and then the respiration. Immediately artificial respiration was resorted to, and a capsule containing three minims of nitrite of amyl was snapped and applied to her nostrils. An enema of brandy and water was also given. These means restored her. The patient had taken sulfolal freely the previous night.

BEWARE OF TABLOIDS. DEATH BY MISTAKING ONE FOR ANOTHER.

THROUGH an error on the part of a chemist in Melbourne, who substituted sulphate of atropine for muriate of morphine, Dr. S. I. Williams met with a tragic death. He was on his way to visit a lady patient, and stopped at a chemist's to obtain some morphine solution. The chemist made a solution with atropine instead, and the doctor, who was in the habit of taking morphine largely, gave himself an injection before entering the house. After administering a dose to the patient, he gave himself a second injection and immediately afterwards became ill, then unconscious, and after lingering a while, sank and died. The patient also exhibited symptoms of poisoning, but recovered.

THE MCCONNELL STUDENT MEMORIAL.

The following summary of the "McConnell Memorial" tablet erected by the students of the Calcutta Medical College to the memory of the late Brigade-Surgeon Lieutenant-Colonel J. F. McCONNELL, who was for many years connected with the College as a Professor, was performed on Monday, 18th June 1898, by Surgeon-Lieutenant-Colonel BOMFORD, Principal of the College, in the main hall of the new building known as Chooney Lall Seal's Dispensary, situated on the grounds south-east of the College. There was a large attendance of the students, and of members of the medical profession. On Dr. BOMFORD being voted to the chair, the Honorary Secretary of the McConnell Memorial Committee read a short report of the work done by the Committee for the purpose of perpetuating the memorial of the late Professor, to whom it was decided to erect a brass memorial tablet. The Committee was indebted to Dr. BOMFORD for his valuable advice and assistance, and for securing the site of the tablet in the Chooney Lall Seal's Dispensary. The Committee also tendered their thanks to Dr. E. BIRD, Dr. J. F. EVANS, Dr. KIDAR NATH DASS, and others, who have helped toward the erection of the tablet. In conclusion, the Secretary requested Dr. BOMFORD to unveil the tablet which is inscribed as follows:—"To the memory of Brigade-Surgeon-Lieutenant-Colonel JAMES FREDERICK PARRY MCCONNELL, M.D., F.R.C.P., I.M.S. for many years on the staff of this hospital, first as Resident Physician and Professor of Pathology and afterwards as second physician and Professor of Materia Medica. Born 18th January 1848, died 24th August 1896. Elected by the students of the Medical College in token of their esteem and regard for one whom they revered as a teacher and loved as a friend." Before the unveiling ceremony was performed, Mr. WOOD read a letter from Mrs. McCONNELL, who expressed her grateful acknowledgment of the kindly feeling which prompted the students to raise a permanent memorial to her husband's memory. Dr. BOMFORD, after unveiling the tablet, which occupies a prominent position in the main hall of the new building, addressed the assembly. He paid a generous tribute to the high attainments and medical skill of Dr. McCONNELL. He had won the esteem of both his patients and the students of the College, in whose education and welfare he always took a deep interest. With the customary vote of thanks to the chair the proceedings terminated.

PLAGUE IN BOMBAY AND IN THE PUNJAB.

The plague figures for the past three days shows that on Saturday there was 5 new cases and 3 deaths; the mortality from all causes being 70, being the same figures as those on the corresponding day last year. Sunday's returns show 18 new cases and 1 death. There were 68 deaths from all causes. On the corresponding date last year there were 7 seizures, with 4 deaths, and 91 deaths from all causes. To-day there were 2 fresh attacks and 4 deaths. There were 60 deaths from all causes. On the same day in 1897 there was 1 seizure. The plague deaths numbered 4, while those from all causes were 68.

The returns for the 12th instant for Karachi show 16 cases and 13 deaths; the totals to date being 2,549 cases and 2,287 deaths.

The plague returns from the infected area continue to be satisfactory and are re-assuring in both the Jullundur and Hoshiarpore districts of the Punjab. The returns of the 7th and 8th instant show no fresh cases and no deaths. Four villages are declared free of plague.

TO DISGUISE BITTER TASTING MEDICINE.

THE *N. Y. Medical Record* says:—"A plant grows in Assam, the botanical name of which is *Gymnetes sylvestre*, which has the peculiar property, when chewed, of temporarily neutralizing the sense of taste as regards sweet and bitter things, while that for sour and saline substances remains unaltered. The Hindus claim that the plant is an antidote to snake-bite. However that may be, it is believed that the plant might be advantageously introduced in our pharmacopoeia as a means of disguising the bitterness of quinine and other disagreeable medicines."

ANOTHER ANGLO-INDIAN SUCCESS.

Among the persons who embarked from Madras the other day up bound for the S. S. *Assam* for England, was Mr. W. C. BOWEN, a son of Mr. JOHN BOWEN, the Frankfort "Papa" who had a pupil of the local medical college. Mr. BOWEN is an Anglo-Indian, and has been the first of the students

for candidates at the last second S. S. Examination; won the medal for Midwifery, the Fraser Memorial Prize and the Johnston Gold Medal. His object in going to England is to compete for the Indian Medical Service.

THE I. M. S. AND THE NEW MEDICAL REFORM BILL.

Nothing officially has yet reached India regarding the manner in which the Indian Medical Service will be affected by the re-organization of the Army Medical Staff. Presumably, says the *Pioneer*, the Secretary of State will send out a despatch on the subject shortly. It is not known when the new Warrant will be issued, but in the *States of Mysore* a fortnight ago, Mr. Powell Williams stated that the delay was in regard to the settlement of "some minor points which required reference to India."

UNQUALIFIED MIDWIVES

The opinion of Mrs. Garrett Anderson, who may be supposed to represent the best opinion of her own sex, and who writes with full knowledge of the fact, that if all women are to have skilled attention, the majority must now and always be attended by men, strongly objects to the measure, and fully recognises the danger of labelling a whole host of unqualified women, and a handful of very indifferently qualified ones with any title whatever implying a Government guarantee.

THE ACTING PRINCIPAL OF THE CALCUTTA MEDICAL COLLEGE.

SURGEON MAJOR G. F. A. HARRIS, L.R.C.P. Lond. (1878), M.R.C.S. Eng. (1877), who has been appointed to act as Principal of the Medical College Hospital while Dr. BOMFORD is away on furlough, has hosts of friends. He was a great favorite in Simla society some eight years ago, when he was Civil Surgeon there. In musical circles Dr. Harris has proved quite an acquisition, and his delightful performances on the violin are pleasurable remembrances of many enjoyable evenings on the hills. But he is a thoroughly good practical physician as well as a trained medical administrator.

SHORT ITEMS.

A heavy drinker, who had suffered for years with symptoms of gastric atony, frequently vomited, and on several occasions found worms in the ejected material. These proved to be larvae of some species of fly. Bachmann prescribed an infusion of Persian insect-powder, with the result of finding in the stools masses of dead and partially digested larvae. The patient had no further symptoms.

The 1st January 1900 has been fixed for the awarding of the Samuel D. Gross prize of \$100 for the best original essay founded upon original investigation on some subject in surgical pathology or surgical practice. Only American citizens may compete, and the essay must not exceed 180 printed pages, octavo size. Further particulars may be obtained from D. J. Swing Mears, 1429 Walnut Street, Philadelphia. Pa. U. S. America.

An exchange reports that in an examination that was made of some "electric bells" sold by a street fakir, it was found that beneath a strip of gauze was a layer of dry mustard. When the wearer perspired a little, the mustard was moistened and set up a burning sensation, and the deluded victim believed a current of electricity was passing through him.

The half-yearly examination for the Fellowship of the Royal Colleges of Surgeons in Ireland came to a conclusion by a conference on 21st May. The number of candidates was unusually large and included a lady graduate in medicine of the University of Calcutta. Miss Cohen passed and was entered on the roll as a Fellow of the College, she being the third lady who has received such honor.

Premature burial, it is reported, will claim a large share of attention in the medical section of the National Exposition which will be held at Turin, in Italy, this year. The object in view is to induce all countries to make laws requiring corpses to be kept for a fixed period before cremation or burial.

Austrian pharmacists ought to make a good thing of it since the people are many and the dispensaries few. Thus while Vienna has a population of 2,244,222, it boasts of 106 pharmacies or 1 for every 19,900 inhabitants. Harbin in central China with her 25,896 souls has but one pharmacy and the proportion of pharmacies to inhabitants is as 1:10,561 in Sudwars,

Any person who spits in a street or in public building under Government control in the District of Columbia is liable to a fine of \$10. California carries things a bit further and the other day sentenced a millionaire to 24 hours' imprisonment in the San Francisco Jail, for spitting where he shouldn't.

In commemoration of the Queen's Diamond Jubilee, the American community in England has presented £1,000 to each of the five leading hospitals in London for the "endowment of a bed in perpetuity" on condition that Americans will be given the preference, though the beds may be used by any one else.

The Mysore Government have put an end to the exclusive privilege of distilling sandalwood oil in that State by rejecting the application of a Coimbatore distiller, Mr. H. S. Lee, who applied for the monopoly for a period of ten years. The monopoly granted to Mr. F. P. Hay, of Hunsur, some years ago, was cancelled in 1896.

A warrant has been issued for the arrest of Pilot Simmonds, of the Rangoon Service, on a charge of defaming Surgeon-Lieutenant-Colonel Thomas, Civil Surgeon and Port Health Officer of Rangoon. The accused, it is alleged, cast reflections upon the manner in which the inspection of female passengers from Calcutta was conducted.

A New York doctor sued a lady patient to recover \$60 for professional services. She opposed his claim as exorbitant and has raised a counter-claim of \$100 for "time lost" as she alleges that the majority of the doctor's visits were more of a social than of professional nature.

The will, with two codicils, of Sir Richard Quain, Bart, M.D., F.R.C.P., &c., who died on 18th March, has been proved by his brother, Mr. F. Quain, of Mincing Lane. The testator's gross estate is sworn at £118,121 13s. 2d., the net personality being £118,820.

Sir William Thomson, President of the Royal College of Surgeons in Ireland, was entertained at dinner by the Vice-President and Council on Saturday, 14th May, in the Shelbourne Hotel. The chair was occupied by Dr. K. L. Swan, the Vice-President.

In case of delirium tremens Crothers uses in the early period, free bathing and cathartics without narcotics. When exhaustion and sleep come on, the latter is encouraged and strychnin nitrate is given as a stimulant. Physical restraint should not be used, unless absolutely necessary.

Ribbert calls attention to the parasitic nature of tumors. The individual cells appear to have all the qualities of parasites, growing independently in the host, excepting that they prey upon it for nourishment without regard to the conditions necessary for its well-being.

I have not failed once for many years, by putting a blister over the fourth and fifth dorsal vertebra, to put an end at once to sickness of pregnancy during the whole remaining period of gestation, no matter at what stage of the case I was consulted." So says Professor Parvix.

The Calcutta Homoeopathic Medical School has just passed twenty-one students as Licentiates, 5 in the First and 16 in the Second Division, among whom one comes from the Punjab. This School of Medicine will be opened on the 22nd without introductory address. This is another Indian Diploma still not under State control.

Mr. Charles Sumner Towne, M.D., M.B., F.R.C.S., L.D.S., has been nominated a Crown Member of the General Council of Medical Education and Registration of the United Kingdom in the vacancy created by the death of the late President, Sir Richard Quain.

The Colonial Office has received a telegram reporting that during the week ending 21st May there were 112 cases of plague in Hong-Kong and 107 deaths resulting from the plague. These figures show some decrease in the ravages of the disease.

The Ohio State Legislature are trying to pass a "bill" for the castration of any man who is convicted of criminal assault on a female and particularly upon any girl under fourteen years of age.

With the waning of the plague in Bombay, the Plague Committee there has been abolished and the Municipality is responsible for the sanitation of the city and affairs generally connected with the Health Department.

Surgeon-Major G. F. Harris, Civil Surgeon of Nagpur, succeeds Surgeon-Lieutenant-Colonel G. Bomford, who takes one year's furlough, as Principal of the Medical College, Calcutta.

Cardinal Gibbons, Bishop Paret and several prominent citizens of Baltimore have started an antivivisection crusade, which is particularly directed against the medical school of Johns Hopkins University.

Auxona has at last adopted a medical examining board, while veterinary surgeons are not permitted to run dry stores in Missouri unless they have qualified and registered as pharmacists.

He was a very able linguist and one day a friend said to him "They tell me professor that you have mastered all of the modern tongues." "Yes," replied he, "all but two my wife and her mothers."

"Know syphilis in all its manifestations and relations," says Dr. W. Osler of Philadelphia, "and what remains to be learned will not stretch the pia mater of a megaloccephalic senior student."

There is every probability of Surgeon-Lieutenant-Colonel Franklin succeeding Surgeon-Lieutenant-Colonel Haye as Inspector-General of Civil Hospitals, Punjab, when the latter proceeds home on furlough.

In septic conditions the patient is often very uncomfortable by reason of dryness of the tongue. A bit of ordinary chewing-gum will usually start the oral secretions and in a very short time give relief.

The Madras Government has sanctioned an outlay of Rs. 1,70,000 for the construction of quarters near the Memorial Hall for the accommodation of the Apothecaries attached to the Madras General Hospital.

Surgeon-Colonel K. MacLeod, Professor of Military Medicine, Army Medical School, Netley, was presented to Her Majesty on the occasion of the Queen's recent visit to Netley Hospital.

The Council of the British Medical Association have just completed the purchase of the Freshford site upon which are situated their premises at the corner of Agar Street and the Strand. The purchase-price was £72,000.

~~Education~~, ~~with~~ ~~effect~~ ~~from~~ ~~1st~~ ~~July~~ ~~next~~.

Surgeon-Major D. G. Crawford, Civil Surgeon of Monghyr, has been appointed to succeed Surgeon-Captain Pilgrim as officiating Civil Surgeon, 24-Parganas.

Surgeon Lieutenant-Colonel C. J. H. Warden, I. M. S., Medical Storekeeper to Government, Bengal Command, is granted two years' furlough.

Surgeon Captain B. B. Grayfoot, I. M. S., officiates as Medical Storekeeper, Bombay Command, *vice* Surgeon-Lieutenant-Colonel J. Parker, on leave.

Dr. Gustmann, of Frankfurt, has published a monograph showing that no less than 80,000 school-children in the German Empire suffer from stuttering.

Professor von Esmarsch, who is over 76 years old, has announced his intention of resigning the chair of surgery which he has held at the University of Kiel since 1857.

Dr T. C. Hayes has been elected Professor of Obstetric Medicine and Diseases of Women and Children, and Dr John Phillips, Lecturer in Practical Obstetrics in King's College.

The Lord Mayor's dinner in support of the London Hospital last week resulted in the collection of £75,000, with annual donations of over £4,000.

Professor Michael Foster will preside over the meetings of Council of the British Association to be held next year at Dover.

Brigade-Surgeon Lieutenant-Colonel W. Flood Murray, Civil Surgeon of Shahabail, has been allowed privilege leave for ninety days, from the 1st instant.

Surgeon-Major J. Grainger, on return from military duty, has been appointed Civil Surgeon of Champaran, during the absence, on deputation, of Surgeon-Major R. R. H. Whitwell.

Danner records a case of external feminine pseudo hermaphroditism, the patients being 33 years old and of Italian descent. After marriage she became twice pregnant.

Surgeon-Lieutenant-Colonel W. Coates, M.D., Civil Surgeon of Lahore, proceeds on six months' leave, and is to be succeeded by Surgeon-Major J. A. Cunningham from Multan.

A very red tongue indicates the need of acids in the system. Five drops of *deute* nitro-hydrochloric acid in water fills the want satisfactorily.

Brief Pointers—Whipped raw eggs possess great nutritive value, and are very easily digested.

Assistant Surgeon P. S. Blaker, of Calcutta, has successfully passed the M.R.C.S. England.

Mr. A. B. Khan has successfully passed the first professional examination of the University of Edinburgh.

Brigade-Surgeon-Lieutenant-Colonel W. McConaghy, Bombay, officiates on the Administrative Staff of the Army.

In future, physicians practising in any part of the State of Texas must pay an "occupation" tax.

On return from military duty, Surgeon-Captain E. Harold Brown, M.D., has been re-appointed Civil Surgeon of Purneah.

DEPARTED INDIAN WORKINGS.

DEPUTY-SURGEON-GENERAL E. E. PARTRIDGE,
F.R.C.S., C.I.E., C.B. & L.
Bengal Medical Service (Retired.)

On 11th May, in the presence of relatives, brother officers, and friends, the mortal remains of SAMUEL BOWEN PARTRIDGE were laid to rest in the cemetery at Norwood.

This distinguished medical officer was born at Cardiff in 1828 and was educated at King's College, London, where he had a most brilliant career, during which he gained many prizes. After passing the Royal College of Surgeons he entered the East India Company's service on the Bengal establishment as an Assistant Surgeon in the year 1852. Shortly after his arrival in India he was ordered to Burmah to join the Bengal Field Force, and after performing excellent service in a variety of ways, on his return to Bengal he served as Civil Surgeon and also with a cavalry regiment. On the outbreak of the mutiny in 1857 he served with a cavalry regiment in Oudh, and when the siege of the Residency of Lucknow commenced he served throughout the whole of that eventful period in Dr FAYAR's house in the garrison, where his energy, activity, and professional knowledge were of the greatest benefit. He was present with the expedition under Colonel BURNES, in which several officers were killed, and he also accompanied the ill-fated expedition to Chinbut, where he had a narrow escape of losing his life. Subsequently he distinguished himself as Field Surgeon in the operations under the Commander-in-Chief at the recapture of Lucknow. For these services he received the brevet promotion of Surgeon, was allowed to count a year's service, and received the thanks of Government in general orders.

The state of his health after all these exceptional services rendered it necessary for him to return to England. After a short stay, during which he became a Fellow of the Royal College of Surgeons, he resumed his duties in India, and was then appointed to the Medical College of Calcutta, in which he had on a former occasion officiated for a short time, as Professor of Anatomy and Surgeon of the Medical College Hospital. He was also an Examiner in the University of Calcutta, a Member of the Senate, and for a short time President of the Medical Faculty of the University. Subsequently, on the retirement of Dr FAYAR, he succeeded to his appointment as First Surgeon and Professor of Surgery in the Medical College Hospital, which appointment he continued to hold with the greatest distinction. In addition he had an extensive practice in Calcutta until 1880, when he retired from the service.

After his return to England Deputy Surgeon-General PARTRIDGE was appointed member of the India Medical Board at the India Office, where he rendered most valuable service, until loss of sight made his resignation of that appointment necessary, to the deep regret of his colleagues and friends.

The news of his death will be received in India, as it has been in this country, with the greatest sorrow. He was held in the highest esteem by everyone who knew him; no man was ever more deservedly loved and respected than he was. His intellectual powers were great, and he was as much characterised by the breadth as by the accuracy of his knowledge; most laborious in his studies, most persevering in pursuing to the end any object which he had undertaken, with the profoundest mathematical problem as with the simplest piece of mechanics he was equally at home. As an anatomist he was unrivalled in the clearness of his demonstrations; as a surgeon he was remarkable not only for his skill as an operator but for his great powers of diagnosis, not

was remarkable for his capacity for dealing with disease in its tropical and other forms, whilst his firm, gentle, and patient method of treatment inspired all who came under his care with confidence and affection. Notwithstanding his great attainments and his remarkable intellectual power, he was as humble as a child. The simplicity of his character was not less marked than its strength. He was naturally beloved by all his brother officers, associates, and pupils, and in fact by everyone who knew him. Whilst so gentle and tender in every way, a spot was not firmer than he where firmness was required. Not even BAYARD himself, or OUTRAM (with whom he was justly compared) better deserved the title of "Chevalier sans peur et sans reproche."

On Deputy Surgeon-General PARTRIDGE's retirement from the India Office the Government signified their approval of his services by creating him a Companion of the Indian Empire. He had previously been made an Honorary Surgeon to the Queen, and had also received a medal and clasp for Burma, and a medal and clasp for the siege and for the recapture of Lucknow.

ALFRED JOHN WALL, M.D. LOND. F.R.C.S.
Indian Medical Service (Retired.)

Dr. WALL, whose death was announced a few days ago, was the son of a medical man who had a large practice in the West End of London. He was born in 1847, and after receiving his preliminary education at Epsom College, matriculated at the University of London in 1865; he then entered St. Mary's Hospital, where he was known as a hard worker and won a number of prizes. In 1868 he gained the Scholarship of Anatomy of his school, a distinction which carried with it the title and duties of Assistant Demonstrator of Anatomy. In 1870 he was appointed Resident Medical Officer of the hospital, becoming Resident Obstetric Officer in 1871. He took the degree of M.B. in 1871, that of B.S. in the following year, and that of M.D. in 1873. In 1872 he became a Fellow of the Royal College of Surgeons of England by examination. He took a high place in the examination for the Indian Medical Service in 1873, and almost immediately on his arrival in India in the early part of 1874 he was appointed Resident Medical Officer at Bhaugulpore.

In 1875, when the Snake Poison Commission was appointed, Dr. WALL was offered a seat on it. The greater part of the practical work of the Commission fell upon him as the youngest member. He held the position for three years, and then, in consequence of failing health, he sent in his resignation. He was twice asked to reconsider this step, but when he adhered to it, he received a letter of thanks from the Government for the valuable work he had done, and was given his choice between an appointment as Residency Medical Officer in Nepal and Deputy Professor of Anatomy in Calcutta. Consideration of health led him to choose the former. Some time afterwards, when travelling on furlough, he contracted malarial fever, which became complicated with pneumonia. In consequence he came home invalided, and never recovered sufficiently to return to India.

In 1868 he published a book entitled *Indian Snake Poisons*, which made his name widely known. He next took up as a subject of special study the cholera, and followed successive outbreaks of the disease over Europe. In Italy and Sicily he was especially distinguished for his services during these. The Municipal Council of one town presented him with an address and the freedom of the town in recognition.

In 1888, as a result of these travels and investigations, he published a book on *Asiatic Cholera*, which was favorably received.

He had always been an indefatigable student of medicine, and he now turned his attention still more earnestly to working at it for many months before he left for Berlin, and Paris.

In December 1897, he left England with the intention of going to the Riviera, in the quiet of which he put his medical notes into form. But while staying in Paris he became so ill that by the advice of a specialist whom he consulted he returned to England and asked his sister to go to Hastings with him.

His condition became so much worse that on 31st April he was brought up, under care, to London, and after consultation with Dr. SAVAGE was placed in charge of a trained attendant under the care of a medical man. On Wednesday, 27th April, he managed to escape from his attendant by going out another way from St. George's Hospital, where he had gone, he said, to call upon some friends on the medical staff there. Although the police were at once communicated with in London, and telegraphed to stop him at the ports of Dover, Folkestone, Harwich, and Newhaven, nothing was heard of him by his friends until the following Monday, when, in consequence of information received by his sister, she went down to Gullford, and identified a body lying there as that of her brother. He had made his way there the previous Thursday and early in the morning had ended his life by stabbing himself to the heart. A post-mortem examination showed that Dr. WALL was suffering from thickening of the membrane of the brain, and this, together with the evidence his sister was able to give at the inquest that evening, caused an immediate and unanimous verdict of "Whist of unsound mind" to be returned, in which the coroner fully concurred.

Another St. Mary's man and intimate friend of Dr. WALL from student days writes of him :—

"In manner he was diffident, quiet, and retiring. He was extremely well informed in every subject of art, science, and literature—the best possible of companions. He talked German, French, and Italian fluently, and was keenly interested in the politics as well as the literature of the countries in which he made his home."

This brilliancy of mind continued to the last, and even whilst under medical care and restraint he captivated all whom he came in contact by his mental power and gentleness of demeanour. Throughout his life Dr. WALL had been singularly abstemious, and of very regular and quiet habits.

SURGEON-GENERAL JAMES IRVING, M.D.
Indian Medical Service (Retired.)

THIS officer died at Clifton on 3rd May at the age of 75. He was born in Edinburgh in 1822 and after graduating in the University of that city in 1843, entered the Bengal Medical Service in 1847. He attained the rank of Deputy Surgeon-General in 1874, and retired with the honorary rank of Surgeon-General on 18th December 1879. He served with distinction throughout the Indian Medley. Most of his executive service was spent in the North-West Provinces, where he held important civil charges. For many years he filled the responsible office of Civil Surgeon of Allahabad, and gained a high reputation as a skillful physician and surgeon. Under a somewhat taciturn manner he possessed a kindly disposition and most charitable heart, and his advice and aid were eagerly sought and highly valued by those in sickness or trouble. He was an observant man and hard worker, and contributed several papers to the medical press, the best known being *Observations on the Fever caused by the Vetch (Lathyrus Sativus)*.

His administrative life was spent in Bengal. He was the first Surgeon-General of the combined provinces of Bengal, Behar, and Orissa when the separation took place in 1876 between military and civil medical administration. His work in this capacity was characterized by competence, independence, and shrewdness. When his retirement he had led a quiet life, devoting himself to books of science and medicine. He was emphatically a conscientious, good man, able, vigilant, and devoted to his profession.

INSANITARY MEASURES IN INDIA.

The death-rate of Madras, averaging, since 1877, 34.7 per 1,000, is considerably larger than that of Bombay or Calcutta, the information and particulars given in the volume on "Sanitary Measures in India" as to the sanitary condition are much more fragmentary and meagre than in the case of these cities. For some unexplained reason the report of the Health Officer for Madras is not published annually, and the report of the Madras Municipality is published without that part treating of its insanitary conditions.

Perhaps the insanitary condition of Madras, given in the appended reports, is, in the opinion of the Indian authorities, too disagreeable to be made public, but, after the revelations published as to Bombay and Calcutta, if this is the case, it very much resembles straining at a gnat and swallowing a camel.

The year 1894 was, for Madras, a comparatively healthy one, the death-rate being the lowest since 1885.

The Army Sanitary Commission remarks on the subject: "It is evident from the small sums expended during the year in improving the drainage and water supply of the city, that no substantial progress has been made towards remedying the radical defects in either, only £6,649 10s. having been expended on the former and £4,363 on the latter. The drainage scheme proposed by Mr. COUSINS may be excellent, but it is very expensive, and the municipal authorities may be excused if they hesitate to undertake a work estimated at £280,000, until after they have become convinced that the effectual drainage of their town cannot be carried out at less expense. When once the main arteries of a good sewerage system are laid down, the sanitation of the town will be much simplified.

A water supply scheme has also been proposed by Mr. COUSINS, but as this would involve an annual expenditure of £40,000, it is considered beyond the utmost strain that the municipal finances could bear. It is clear from the description given of the water supplied to the city that this should undergo filtration before distribution, but as it has not a sufficient head to admit of its being conveyed on to the filter beds unless first lifted by pumping, and as the cost of this would be prohibitive, the difficulty seems to be for the present insurmountable.

Other improvements having for their object the more efficient removal of night soil and refuse, the prevention of intramural burial, the opening up of overcrowded parts of the town, the admission of sea water into the stagnant and fetid Cooum river, and such like, need not be interrupted because of the delay in arriving at a decision regarding the proposed drainage and water supply. But until these latter are undertaken and carried out, Madras will almost certainly continue to enjoy the unenviable reputation of being the unhealthiest of the three Presidency towns. All other improvements are of comparatively minor importance, and their effects, as measured by the death-rate, will probably be unappreciable.

The death-rate fell from 41, in 1893, to 30.5 per 1,000, but was still considerably higher than that recorded in the other two Presidency towns, although in these latter the year was an exceptionally unhealthy one. Of the chief diseases, fever was, as usual, credited with the larger share of the deaths. Although less fatal than during the preceding year, the mortality caused by it was much in excess of the average for the previous 10 years. Until Madras is provided with an efficient drainage and sewerage system, diminution in the annual mortality from fever need not be looked for. On the contrary, as pollution and sewage logging of the soil must go on increasing in the absence of effectual drainage, the death-rate from fever may be expected to likewise increase. The mortality from dysentery and diarrhoea, although high, was below the average. The indifferent quality of the water supply doubtless favours the prevalence of these diseases.

The number of deaths in 1894 was 12,442, a decrease of 10.5 per cent. under 1893, or 4,265, or 30.55 per cent. under 1892, or 7,330, or 52.5 per cent. under 1891, and 10,470, or 75.5 per cent. under 1890. The death-rate per 1,000 was 30.5 in 1894, 41 in 1893, 53.5 in 1892, and 64 in 1891. As in the case of Bombay, statistics date from 1877, and the average death-rate per 1,000 for the period

1877-94, is 44.2. The highest death-rate per 1,000, was in 1877; the nearest to the average, 44.2, in 1888; and the lowest, 34.7 per 1,000, in 1879. Dividing the whole period into three terms of seven years, gives an average death-rate of 53.73 per 1,000 for 1877-83, of 46.17 per 1,000 for 1884-90; and of 34.25 per 1,000 for 1891-97. Dividing the period into seven terms of three years, there was considerable fluctuation, the highest rate, 64.9 per 1,000, being in 1877-79; the nearest to the average, 45.8 per 1,000, in 1874-76, and the lowest, 37.8 per 1,000, in 1894-96. Bearing in mind the necessary caution as to the value of registration statistics in India, these figures show a great improvement in the middle period which was not kept up in the third period.

The great difficulty in dealing with the problem of Madras sanitation lies in the fact that the high death-rate is not the result of any one cause, but of a conjunction of nearly all the causes that affect mortality all over the world. The most important, briefly, are, an insufficient water-supply, defective drainage, and, over a considerable portion of the municipality no drainage at all; a poor, well-laden with organic impurity, a putrid and fermenting surface water rising comparatively near the surface, want of open spaces in some parts of the town, crowded tenements for the poor, overcrowded and ill-ventilated houses for the middle classes, in many cases directly connected with the subterranean water by wells in their interior, burial grounds and slaughter houses in the city, and lastly, the general social, conjugal, and religious habits of the people. These are matters which can only be remedied by a heavy expenditure of money and years of systematic and patient work. There can be no doubt that the high death-rate is due to local conditions and not to climatic influence, for both Europeans and natives who live in well-built houses in the better parts of the town, and are properly clothed and fed, enjoy a comparative immunity from disease and death.

The chief causes of death in Madras were fever, dysentery, and measles, and formed 53.66 per cent. of the total. Deaths from fever, 37.05 of the whole, were 6,138, a decrease of 500, or 8.02 per cent., under 1893. Although this is an improvement, it cannot be considered satisfactory, as it is still far above the average. The death rate per 1,000, 78.5, fluctuated from 8.5 in the Eighth Division, South Ward, to 21.7 in the Third Division, Centre Ward. The mortality was much less in the rural and suburban areas in the south and south-west of the municipality, where aggregation is less, and there are plenty of trees to dry the ground, than in the crowded area of Black Town.

The general conditions which produce a heavy mortality from fever in Madras are the general insanitary conditions which prevail, especially those due to the want of good drainage and pure air. The result is materially affected by the want of ventilation and overcrowding of houses, in which people breathe air vitiated by organic matter given off by the lungs and skin mingled with which are the gases from the sewage-polluted grounds and from the drains both inside and in the streets beneath the door and windows.

It is a matter of the greatest difficulty to diagnose a non-eruptive fever among people who rarely attend a hospital or avail themselves of the ministrations of a medical attendant of any grade, and who, for the most part, die in their parishes without being seen by anyone but their relatives.

According to a report of Mr. COUSINS, who visited Madras and examined the drainage and water-supply, Madras is drained on the open-channel system; that is, the drainage of the houses is discharged into open channels in the street, some of which are formed in the soil without brickwork, concrete, or any proper construction, whilst others are of defective brickwork with open joints, &c.

The open channels in Black Town and a few other parts of the district have been recently reconstructed in a very superior manner to those generally found. Under the system now pursued, all rubbish, dirt, &c., and the principal part of the solid excrementations, are collected and removed by the conservancy carts and disposed of in various ways. The fouled water from the houses, the urine, part of the sewage mixed with the water used in the daily washing out of privies, bath, and sink, &c., are discharged through the house drains into the open channels in the street.

House drains are usually constructed of very imperfect brickwork, having open joints and generally laid but a few inches below the level of the flags of the houses with

inadequate. The soil for some distance round these drains must of necessity be saturated with sewage, which must injuriously affect the health of the occupants. These drains usually terminate at the front walls of the houses at a height of 2 or 3 feet above the public drains in the street; here the sewage pours or trickles down the surface of the front walls of houses until it reaches the open channel, which conveys the sewage to a large open drain. Then it passes on into other wider and deeper drains, until, eventually, it is discharged into covered sewers, which convey the sewage to pumping station where it is pumped on to one or other of the 11 sewage farms.

When the engines or pumps at these stations are not at work, or if there is more sewage than the land and pumps can deal with, the overflow at such times is discharged directly either into the River Cooum, the Buckingham or Junction canals, or into the sea.

In some parts drains are found which do not connect with sewage farms, but empty their contents into the river and canals or stagnant pools. Thus the sanitary aspect of a Madras street presents the spectacle of a row of open house drains on either side of it discharging sewage matter into two open public drains. It is no matter for wonder that in all parts of the town the subtle odour of sewage, more or less strong, is distinctly apparent; and when the abnormally high death-rate accompanied by these unsanitary conditions are considered together with the moral effect which the constant sight of the filth must have on the native mind, no more crushing arguments against the open channel system could be adduced. One disgusting practice alone under this system should be sufficient to ensure its abolition—the present method of the collection of the faeces by men and women.

If no back entrance exists to the house, the native must enter the back yard by a small covered inlet generally provided with a door. This opens from the street to the privy, where the man or woman collects the excreta of the household and conveys it to the pails in the carts in the streets, which are provided for its removal to the depot. The privy is generally washed out at the same time, the fouled water going into the open drain in the street. I cannot speak too strongly against such a repulsive and loathsome practice. To the inhabitants it must be a source of supreme disgust, while its degrading influence upon those carrying out such work cannot be over-estimated.

Even in Black Town, where the open-channel system is seen at its best, the concurrent evils can be plainly noted; but in other parts, where, either through choked-up channels or insufficient gradients, the sewage remains stagnant or soaks through badly constructed or broken drains into the subsoil, the evil effects are patent to all.

A large proportion of the native population are shopkeepers; these, with their assistants sit month after month vending their wares in the impure atmosphere arising from the open drains immediately in front of their shops while their customers stand over the same foul-smelling channel to make their purchases. The wonder is, not that the mortality returns are so high, but that they are so low under these conditions.

The solid contents of the sewage settle in the bed of the River Cooum, and form a layer upon layer of horrible deposit, while the fluid portion emits the stench which has gained for the river its unenviable notoriety. As the hot weather increases, the river gains in potency until the noxious exhalations are apparent at a considerable distance.

The nuisance and inconvenience which must result for the numerous dwellers upon or near the banks must be very great; many large buildings, such as Government House, the Government Office, the Senate House, and the Penitentiary, are near it; whilst the effects on the inmates of the General Hospital and the Women's and Children's Hospital are matters for grave consideration. The river, also, breeds myriads of organisms, and is credited with producing the plagues of mosquitoes which at times infest Madras. In this cesspool of stagnant filth men may be seen every day fishing, and doubtless the results of their labors are vended for human consumption. Thus the river in its present condition is a standing menace to the health of the inhabitants of Madras during the time it remains a motionless pool in the centre of the town; even when tidal it is a source of great danger under the present conditions, as the decomposed and decomposing deposits on the bed of the river are disturbed by the action of the tidal waters, and thus permitted to freely throw off obnoxious gases. The greater part of this sediment

would doubtless be removed when the river is in flood and flowing freely onwards to the sea, but this may only occur for two or three months in each year; for the sedimenting time or ten months the mouth of the river is blocked by the bar, and the matters held in suspension once more deposited.

No scheme of drainage for the town of Madras will be in the remotest degree satisfactory unless it provides for the total elimination of all sewage matter from the River Cooum.

Although the report was written in the middle of 1895, and in October 1895 the Army Sanitary Commission stated that Madras had arrived at a critical point in its sanitary history, it was not until last March that the Madras Government sanctioned the long-contemplated drainage scheme, but the main part thereof was postponed pending arrangements between the Government and the Municipality.

The deaths from dysentery and diarrhoea were 2,392, a decrease of 814, or 17.66 per cent. under 1893.

The principal water supply of the town is received from the Red Hills tank, arriving at the town after flowing through about six miles of more or less inhabited area. The distribution is on the "constant system," but pressure is insufficient, and at times the pipes at certain points are empty, irrespective of the whole town supply being turned off for two hours weekly. Flushing pipes dip directly over and into drains, certain mains pass through sewers, pipes to fountains pass beneath permeable gutters, and run close to old underground permeable drains; contamination by aspiration of air on fluids is therefore possible during temporary cessations of flow.

Another source of water-supply—the "town wells"—and that used by the British troops is derived from the subsoil flow in a belt of sand within the inhabited area of the town, and in former days yielded a fairly pure supply, but the wells are within the subsoil flow of the site of a sewage farm that is not under-drained, the farm being made of rubbish deposits that must contain tons of faecal matter. It is not to be wondered at that the water is now pronounced chemically bad. Typhoid fever has been frequent and coincident with a general fall of the subsoil water level of the town site, and the source must therefore be regarded with suspicion, though no direct proof of specific contamination has been forthcoming. The conservancy arrangements of the municipality are bad in the extreme, both staff and plant being below actual requirements. Many of the old tanks of the town have been in former days, and up to the present time are, filled with town rubbish, and, therefore—in the absence of a complete night-soil system—with much excreta. Without entering into further details, it stands to reason that the subsoil of the town is peculiarly and unusually contaminated with organic matter, and is unfit for use as a water-collecting area.

No substantial improvement was produced during the year in the sanitation of Madras, but £40,000 was borrowed for expenditure upon the improvement and extension of the water supply. A scheme for the purification of the Cooum was approved by Government, and estimates for carrying it out were under preparation. The drainage scheme prepared by Mr. COUBINS was also under consideration, but the Government were of opinion that the cost of its execution, which would necessitate an increase of 68 per cent in the taxation of the city, was prohibitive, and that native habits and the conditions existing in the city would render the closed connection with houses proposed in it unworkable, and a source of danger rather than of benefit to the inhabitants. A modification of the scheme has since been proposed by a committee of the Commissioners and was under the consideration of the Government. Estimates were also drawn up for carrying out Mr. COUBINS' scheme of water supply. In addition to the above proposals for the more satisfactory disposal of the rubbish of the city were being matured, and other improvements were in contemplation. The execution of these schemes of improvement is expected to produce a real advance in the sanitary condition of the city.

The municipality was carefully inspected during the year. The highly unhealthy condition of the city having attracted the attention of the Madras Government, in 1890, a special committee was appointed to advise as to the nature of the urgent sanitary improvements, in connection with drainage and water supply, that were considered necessary. Rough schemes were formulated, and the Government, on the advice of the committee, employed a European expert sanitary engineer to advise and estimate for complete schemes—the Public Health Engineer.

(To be continued.)

VITAL STATISTICS OF CALCUTTA.

Statement of Deaths from Principal Diseases in Calcutta during the week ending 14th May to the 4th June 1896.

Week ending.	Cholera.	Small-pox.	Fever.	Bowel complaints.	Also other diseases.	Total.	Total population, according to the census of 1891.	Ratio per 1,000 of population per annum.
14th May	24	4	92	57	179	356	6,61,540	27.2
31st May	17	1	101	63	217	393	...	30.4

4th June	7	3	79	67	179	336	...	25.6

Current Medical Literature.

MEDICINE.

Varieties of Diabetes Mellitus.

DR. LEPINE shows that clinical observation distinguishes between certain varieties of diabetes mellitus. In the nervous variety the glycosuria is often quite moderate, and may even disappear, leaving behind a simple polyuria. The type developed under the influence of gout in arthritic individuals is associated with an intermittent but abundant glycosuria, and is comparatively benign. Certain diseases of the pancreas, such as calculi of Wirsung's canal and sclerosis of the whole parenchyma, may be followed by a rapid and dangerous diabetes. There are other varieties difficult to classify. Each case is constituted by several pathogenic elements of varying importance. Hyperglycemia may be caused by lack of the physical storing of glycogen by the hepatic cells (asomylia) and this condition of the cells may be caused by lesions or irritation of the nervous system, various poisons, ablation of the pancreas, etc. Another cause may lie in the excess of primary proteolysis and in glyco-genesis without glycogen. It is a positive fact that in many cases of diabetes there is exaggerated destruction of nitrogen, and some diabetic patients excrete large quantities of sugar after the ingestion of much meat. There is ample justification of the assumption that sugar produced in the organism may be derived directly from albuminoid substances. In certain forms of diabetes the sugar may be lacking. It may disappear either by transformation into fat or by oxidation. The inadequacy of one or other of these two processes may constitute a pathogenic element of diabetes. There may also be a reduction in the amount of the glycolytic ferment, and the renal element must not be overlooked. In pancreatic diabetes there is asomylia, diminution of the glycolytic ferment, diminished formation of fat, diminished production of sugar. In the nervous variety there is asomylia, exaggerated hepatic glyco-genesis, and diminution of glycolytic ferment. The theory of multiple factors explains the infinite varieties of the disease.—*Ann. Med.*

Splenic Tumor in Rachitis.

DR. VON STAECK says, that in one hundred cases of rachitis the diagnosis of splenic enlargement was made sixty-eight times. The situation of the tumor is the same as in the adult. There is no ground for the belief that the spleen is relatively larger during the first year of life than in the later years of childhood, yet during the first year the spleen shows an extraordinary tendency to enlarge under pathological conditions. The splenic enlargement, in the cases of rachitis examined, was generally medium. There is no constant relation between the severity of rachitic bone changes and the amount of enlargement of the spleen; the latter is more constantly governed by the severity of the accompanying anemia. Autopsies on rachitic children (when other causes of splenic enlargement, e.g., infectious diseases, could be excluded) showed a splenic tumor in over fifty per cent. of the cases.

The tumor was more generally found in those presenting marked rachitic bone alterations, yet even if the latter be very severe the enlargement may not exist. The splenic tumor, either macroscopically or microscopically, shows nothing characteristic. The writer concludes that tumefaction of the spleen can hardly be considered a symptom of rachitis in children, and that it is caused by the same unknown noxious product that produces the rachitis.—*N. Y. Med. Jour.*

Differential Diagnosis between Gastritis and Cancer of the Stomach.

CHAUFFARD recognising the difficulty in differentiating hypo-peptic gastritis from cancer of the stomach, says that variation in weight of the patient is a sign of great value. As a general rule, if a cancerous patient is put upon suitable diet and is given a great deal of rest, his weight will slightly increase, perhaps to the extent of three or four pounds. Such increase in weight is invariably followed by a progressive loss which continues without interruption until the patient is emaciated. A dyspeptic patient, on the other hand, will continue, under suitable treatment, to gain weight until a maximum point is reached, at which the weight is constantly maintained—a point which may be fifteen or twenty, or even thirty pounds in excess of the weight at the beginning of the treatment.—*Med. News*

Pyretic Drugs.

In his Croonian lectures, Dr. W. HALE WHITE stated there are many pyretic drugs. Thus strychnine and caffeine both raise the temperature a little and large doses of quinine cause considerable elevation of temperature, which may suddenly rise to 104°F. in belladonna poisoning; but the rise produced by *δ* tetrahydrocannabylamine in the pulse, respiration and temperature so resembles in extent and rapidity that caused by injuries to corpus striatum that it is probable that in this drug we have an agent that stimulates the thermogenic centre without exciting the motor function of muscle; or, in other words, this drug, acting on the muscles through the central nervous system, is capable of producing a rise of 8° to 9.9°F. in one hour, and that if it is to be used as fever remedy, great caution is required on account of its marked effect on the heart.—*Brit. Med. Jour.*

Chronic Glycosuria.

In a paper presented to the Académie de Médecine, Worms who has a wide clinical experience of this disease, advises patients to determine each his own diet and take plenty of out-door exercise if they wish to ensure longevity. He examined the urine of 100 brain workers, who led sedentary lives and found considerable quantities of sugar in 7 of them; whereas among 607 artisans and laborers sugar was not found in one. After excluding the hopeless cases he classifies diabetes as:—(1) Those who have large proportions of sugar, but easily reducible. (2) Those whose sugar is not reducible; and (3) those in whom the sugar altogether ceases, but reappears after a long interval—sometimes as long as 12 months generally after some violent emotion, and this is particularly the case in gouty subjects.—*Cal. Jour. of Med.*

SURGERY.

Transplantation of Skin Grafts without Pedicle from one part of the Body to another and from one Patient to another.

HAYES, some years ago, operated on a woman for ptoch, Dr. C. BELL TAYLOR inadvertently excised rather more than he wanted in of the upper lid; but finding it impracticable to transplant a piece of skin with pedicle from the immediate neighbourhood, he replaced the apparently dead eyelid which took kindly to his old quarters and the shrinkage due to its temporary desiccation (transplanted skin shrinks to nearly 2/3 of its original size) sufficed to restore the normal position of the lid. Hence this he has frequently transplanted skin from one part of the body to another, and from one patient to another. On one occasion he cured extensive symblepharon by transplanting a large piece of skin on to the surface of the eyelid itself and in another case where the facial flaps were almost completely destroyed by burn so to make it impossible to find healthy tissue in the neighbourhood of the split, he restored an eyelid by a piece of skin taken from the forearm. The points necessary to success are (1) clear away subcutaneous tissue, (2) clean, approximate the edges, (3) apply pressure and (4) keep the flap warm.—*Lancet*.

Lumbar Nephropexy without Suturing.

SMITH, who strongly objects to the practice of incising and detaching the fibrous capsule and thus permanently and seriously injuring the kidney, relies on extensive excision of the adipose capsule in the fixation of movable kidney and altogether dispensing with sutures, trusts exclusively to (1) extensive removal of the perirenal fat, (2) sacrifice of the fibrous capsule, (3) direct temporary support of the kidney by a strip of iodoform gauze, (4) plugging the wound with gauze, and (5) prolonged rest on the back with (6) localised compression of the front of the abdomen.—*Jour. Amer. Med. Assn.*

Spontaneous Straightening of Bickety Curvatures of the Leg.

FROM a study of a large number of cases at the Tubingen Clinic, KAMPE concludes: (1) The greater number of all cases of bickety curvature of the legs undergo spontaneous cure. Of the author's cases, all severe, seventy-five per cent. were cured, 15.3 per cent. improved, in only 9.7 per cent. was there no improvement of the deformity. (2) The process of spontaneous straightening lasts usually from two to four years. If the curvature began in the first or second year of life the legs are quite straight by the fourth or fifth. (3) If the curvatures are unchanged by the sixth year, spontaneous cure does not take place at all. There are always cases of most severe general rachitis. (4) The chief aim in treatment is to improve the general health so as to strengthen the muscles. In KAMPE's experience, as soon as the disease is past the acute stage, being about on the legs is not detrimental, but, on the contrary, helps the cure. Orthopaedic treatment by plaster of Paris, splints, etc., is not necessary. Osteotomy is indicated only when the curvatures persist after the sixth year.—*Canad. Pres.*

Operative Surgery of Gastric Ulcer.

THOMPSON gives the indications for surgical intervention in gastric ulcer: (1) In general it is absolutely necessary as early as possible before perforation, and to reach out the abdomen. Since 1902 the mortality after operation has fallen to 33.34 per cent., and without operation the condition is almost hopelessly fatal. (2) For sten-

ture of the pylorus. In this condition it is best to distinguish obstruction from swelling of the pylorus, and the latter from pyloric spasm from the former. In the latter there are three possible operations: (a) resection of the pylorus; (b) gastro-enterostomy; (c) pyloroplasty. Of these the first is the most dangerous, and has no advantages over the others, unless the ulcer can be excised with the pylorus. Pyloroplasty is not applicable if the ulcer extends to the pylorus, or where the pylorus is adherent, and its walls have lost their softness. When there is choice between the second and third methods, THOMPSON prefers pyloroplasty. (3) Operation may be required for adhesions or abscesses in connection with the ulcer. These are mostly very hard to diagnose, but it must be remembered that in some cases of persistent pain exploratory laparotomy is justified. (4) For hæmatemesis. Since sudden death is the exception, and many cases recover with medical treatment, the propriety of operation is still doubtful. HARRMAN'S 12 cases gave 8 deaths and 4 recoveries. The author believes the chief point to be the quantity of blood lost. For violent hæmorrhage laparotomy has almost always failed. Sometimes the infiltration of the surrounding tissues has rendered excision of the ulcer or ligaturing the bleeding vessel impossible. Often the bleeding comes from a branch of the splenic artery, whose territory is very difficult to reach, and sometimes the ulcer has been too small to be found. For slighter hæmorrhages which become dangerous through repetition operation may be successful; usually pyloroplasty or more often gastro-enterostomy have been performed in such cases with a view to procuring rest of the stomach, and consequently of the ulcer and its healing. (5) This last consideration has led some to propose gastro-enterostomy for cases of uncomplicated gastric ulcer. The general death-rate for all cases of gastric ulcer is 25 to 30 per cent. for gastro-enterostomy only 16.2 per cent., and therefore the operation has less danger than the disease. Another advantage of not waiting for complications is that the patient is in better health. At any rate cases which do not improve with medical treatment in a reasonable time should be treated surgically.—*Brit. Med. Jour.*

A Story with a Moral.

DR. FREDERICK HOLME WIGGIN said that the great mortality following operations for intestinal obstruction was due, in his opinion, to the delay in operating. The usual history was that the attending physician had purged the patient freely with salines, and had lost very valuable time before calling in a surgeon. He referred to a case in which the patient had refused operation and the friends had besought him to give morphine. He had given one dose, but, finding no amelioration of the symptoms, he had positively refused to continue its administration. Finally consent was obtained to an operation, and when it was performed, it was evident, from the beginning gangrene of the parts that had he yielded to their entreaties and continued the morphine, death would have been the result. It should be remembered that occlusion of the large intestine might exist for ten days or two weeks without any marked symptoms, except vomiting. In chronic cases there was often a history of a blow or some injury which would aid one in locating the seat of the trouble. If there was a history of obstruction, and rectal examination and digital examination gave a negative result, there was reason for believing that the case was one of intestinal obstruction. The general practitioner often made the diagnosis of intestinal obstruction, but delayed consulting a surgeon until he had destroyed the particular nature of the obstruction.—*N. Y. Med. J.*

OBSTETRIC AND GYNECOLOGY.**Vaginal Cesarean Section with Total Extirpation of a Carcinomatous Uterus at Term.**

SURVEY applied the procedure advocated in DUNBAR'S monograph on vaginal Cesarean section. The child was saved alive, but the mother died two days after the operation of heart failure. The patient was 37 years of age, and had had five children by two marriages, and sought advice only two weeks before her expected confinement on account of repeated and offensive discharges of blood. A cancerous mass, the size of a man's fist, was discovered arising from the posterior wall of the cervix. Part of the anterior lip and the whole of the unpravginal portion of the cervix were free from growth. After the usual preparations the cancerous mass was looped out and the tumour remains energetically disinfectant. Later in the day the operation was performed. The whole of the posterior lip of the cervix was first removed, the bladder was separated off, and the lower part of each broad ligament ligatured. The anterior lip was then split, and the division carried on to the body of the uterus, the cut edges being bound with ligatures to control bleeding. The bag of membranes was ruptured, and the head of the child was driven down, rendering forceps necessary, it had been intended to turn. The child was born partly asphyxiated, but was soon revived with a few swings on SCHULTZ'S plan. The placenta was at once removed, the anterior uterine wall folded in, and the fundus turned out, after which the posterior wall was split, and each half of the uterus removed after securing the broad ligament with clamps. The patient went on well till the morrow midday, after this she gradually sank of heart failure. The author speaks well of vaginal Cesarean section, but inasmuch as the patient might, he thinks, have recovered if he had postponed the total extirpation of the uterus, he recommends that this part of the operation should always be postponed if the delivery procedures are difficult or the patient weak, but with a small child and favorable conditions he counsels completion of the operation at one sitting.—*Brit. Med. Jour.*

Hydramnios in Several Successive Pregnancies.

DR. CARLIN E. LINBERG reports the case of a lady who had four hydramniotic pregnancies in succession. She first aborted at eight months with a female child weighing six pounds whose head and face were perfect, but the body and limbs horribly distorted. This was the first pregnancy in the lady's fifth year of married life and twenty third of age. Five years later a second pregnancy ended in abortion at the third month, a mass of about the size of a foetal head being cast off, which proved to be an amniotic sac containing a foetus of the size of a white bean, without any sign of placental attachment. Four years later the lady had married again, when at eight months another discharge of water occurred, and a male child weighing five pounds and deformed in the lower extremities was born. The placenta, as before, was exceedingly small. The child lived and with care has become a hearty boy, the deformities having been corrected. A subsequent pregnancy ended in abortion with a bag of water at the third month. The lady is healthy in every way and has nothing peculiar in her family history, and her pregnancies and recoveries have all been uneventful.—*N. Y. Med. Rec.*

Puerperal Septicæmia.

NOBIS sums up as follows:—1. Puerperal sepsis is caused most frequently by the physician or midwife. 2. In a particular woman internal examinations should be made as infrequently as possible. 3. Antepartum and post-partum vaginal irrigations are to be omitted. 4. At the first symptom of puerperal sepsis, circumscribed pelvic inflammations should not be overlooked and operative interference should be undertaken at the proper time. 5. For the further treatment, energetic stimulation, intravenous, subcutaneous, and intra-rectal injections of a dechlorinated salt solution, and insulin play a most important part. 6. The use of antistreptococcus serum proves efficacious only in those cases in which a pure streptococcus infection exists.—*N. Y. Med. Rec.*

Pelvic Disease in Women the Subject of Hereditary Syphilis.

HAVING to deal with a 'virgo intacta' for white backache and leucorrhœa there was no apparent origin, Dr. J. SHAW-MACKENZIE, who thinks it especially difficult and undesirable to inquire too much into histories in such cases, noted that on her face and at the angles of her mouth and nose were several cicatrices left by an eruptive condition in infancy, and which no doubt was syphilitic. Further investigations led him to conclude:—(1). That the acquired syphilitic origin of pelvic disease in parous women was largely overlooked and rarely mentioned at the present day, though (2) few mothers of syphilitic offspring escaped some subsequent uterine, ovarian or tubal disease, and (3) these might be transmitted through the mother to the third generation much more commonly than is supposed. He lays great stress on the fact that (1) the subjects of hereditary had recurring sorethroat, falling out of hair, leucorrhœa, menorrhagia, sometimes Hutchinsonian teeth, and frequently pelvic inflammatory disease, which marriage and conception aggravated; (2) sisters sometimes presented similar symptoms, (3) there is positive or suggestive history of syphilis in the patient's father and none in her husband, while (4) her mother presents a suggestive history of abortions, premature births, dead children, possibly floodings and puerperal fever.—*Glin Jour.*

Operation for the Prevention of Conception.

A WOMAN, who was still young, had fallen into a state of grave anemia after seven successive confinements, and Dr. KREMER, Professor of Obstetrics and Gynecology at Heidelberg, performed the following operation, according to *La Semaine Médicale*, in order to prevent further pregnancies. By a median vaginal incision he penetrated the peritoneal cavity, then drawing the tubes into view he placed around them two catgut ligatures. This done, he performed vaginal hysteropexy immediately above the internal orifice of the uterus, introducing into the vesico-uterine cavity a strip of gauze and suturing the wound into the vagina so as to leave a small opening for the passage of the drainage. Apart from a little fever and slight suprapubic pain there were no sequelæ. This process of artificial sterilisation possesses the advantages over castration of being a less serious operation and of not bringing in its train the nervous troubles that double ovariectomy does. Dr. KREMER thinks this could be done in certain grave affections (anæmia, pulmonary and cardiac lesions) which render pregnancy dangerous. He acknowledges that from a moral point of view the legitimacy of this operation could be questioned, and believes it ought not to be performed without the written consent of the parties concerned and a statement of the motives for such intervention.—*N. Y. Med. Rec.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

The Physiology of Anesthetics.

MANY valuable and voluminous papers on anesthetics have appeared during the year, notably one in which HILL carried further his research, published this year in the *Journal of Physiology*. He pointed out that the circulation of the blood depends upon the vaso-motor mechanism being intact.

The abdominal wall is able to support the veins and so prevents their distention under the hydrostatic pressure of gravity. Muscular contraction during expiration compresses the hepatic and other veins helping to fill the right heart. When the vaso-motor tone is maintained the splanchnic area abrogates the effect of gravity. In vaso-motor paralysis gravity at once causes accumulation of blood in the abdominal vessels. This leads to anemia of the brain and the respiratory center is driven to greater activity. Powerful muscular movements take place and the blood again enters the right heart. Contraction of the abdominal muscles limits the outflow from the splanchnic vessels. When both the vaso-motor tone and the respiratory pump are paralyzed the circulation cannot be maintained in the "feet down" position. Chloroform paralyzes both these factors of the circulation. No amount of compression of the abdominal veins will produce paralytic distention of the heart. Both chloroform and asphyxia will do so. HILL finds that such a condition is at once relieved by dropping the patient into the "feet down" position as the blood at once flows from the right heart by the force of gravity. The teaching of physiology has thus a practical value and tells us that the vaso-motor paralysis is a danger to be looked for and provided against as well as the always accepted danger of respiratory paralysis, a condition which HILL finds may arise from anemia of the brain centers as well as from accumulation of the drug.—*Med. Age.*

Man's Ancestors.

WE can point now to the long since extinct ancestors of the lowest vertebrates, we are able to introduce all the reptiles, the birds, and the mammals to their primitive prototypes. In the mammals particularly, gap after gap which seemed to separate species and genera and orders has been successfully spanned by the discovery of intermediate forms; and we have now the genealogical types of the deer, musk, horse, tapir, rhinoceros, cat, lemur, monkey, and many others; and yet, as regards the pedigree of man, we are still in the dark. Professor HUXLEY's impressive words still hold. Paleontology sheds no light on man's origin for, "so far as that light is bright, it shows him substantially as he is now, and when it grows dim it permits us to see no sign that he was other than he is now." Missing links to connect the human species with the demonstrated evolutionary law of the world of life and matter are quoted, of course; but it seems well nigh impossible to prove that an alleged link is anything more than an extreme instance of some particular type. And it is pretty certain that if missing links exist, they must be sought for in a period much farther back than we are at present able to explore.—*N. Y. Med. Rec.*

Acquired Immunity.

QUOTING from Marshall statistics of 23 second attacks of scarlet fever, 37 of measles, 514 of small-pox and a large number of typhoid and of whooping cough, and arguing on the strength of Voorn's proofs of precisely similar immunity as that conferred by injections of attenuated cultures of specific

serum being obtained by serum from perfectly healthy animals GOLTSTEIN dismisses the prophylactic claims of vaccination as so much rubbish and considers it just as justifiable to conclude that because a man does not have an infectious disease twice he has become immune to it through the first attack, as it would be to insist that the same person should win the first prize in a lottery twice running. He maintains that the experimentally established immunity of PASTEUR is not true immunity but merely a heightened power of resistance, and urges that human acquired immunity should be investigated without reference to experiments on animals. The rarity of the recurrence of infectious disease in the same person he attributes to the law of probabilities aided by three factors:—(1) Many diseases, such as diphtheria, being particularly associated with the early years of life, the patient exposed to a second infection has very often passed the age of especial liability (2). Other affections, such as typhus, occurring typically in short infrequent epidemics, minimize the subjects chances of re-attack. (3) Deadly diseases, such as cholera, spare those only who are most resistant, and in these persons the probabilities of recurrence are indeed few. Again, acquired immunity not being transmissible family and racial non susceptibility to disease cannot be explained except by heightened resistance by the elimination of the weak in the struggle for existence, while in many of the exanthemata the true cause of immunity may be due to toughening of the skin by the first eruption preventing cutaneous infection.—*Brit. Med. Jour.*

On the Sputum of Pulmonary Carcinoma.

P. HAMPLEN claims that carcinoma of the lungs is not very rare, nor is the diagnosis so very difficult. He admits, however, that the symptoms produced by isolated, oftentimes metastatic carcinomatous tumors are very obscure. On the other hand, diffuse carcinomas of the lung, generally primary, gives a fairly characteristic symptom complex: 1, symptoms of unilateral consolidation of lung tissue, causing either retraction or expansion of the thorax; 2, irritation of the bronchi, producing cough and expectoration; 3, irritation of the pleura, producing exudation of all kinds; 4, pressure on the neighboring organs, particularly on the nerves and veins; 5 increasing cachexia. Added to these symptoms is the character of the sputum. Macroscopically the bloody character of the sputum is to be observed; generally the hæmoptysis is very mild and recurs two or three times; more rarely the pulmonary hemorrhage lasts a long time, though at no time is the bleeding copious. The hemorrhagic character of the sputum, its tenacious consistence, its early occurrence—these facts are of great diagnostic importance. The discovery of carcinomatous tissue in the sputum is of course almost pathognomonic, though this is extremely rarely found. Microscopically the writer lays great stress upon the discovery of polygonal alveolar epithelium, often pigmented, which in isolated cases is found in the sputum of many diseases, very rarely in normal sputum. If, on repeated or even on comparatively few examinations, such polymorphous polygonal epithelial cells alone are found, or there are found in overwhelming numbers cells with sharp contour, containing nucleoli the cells either occurring in masses or separated, the inference is that a pulmonary new growth is present; indeed, the writer claims that the above microscopical picture presents itself only in cases of malignant tumour of the lung. The above described cells are easily differentiated from the pavement and cylindrical cells; besides, the latter contain no pigment.—*N. Y. Med. Rec.*

PUBLIC AND DOMESTIC HYGIENE AND SANITATION.

Does the Cooking of Animal Food Kill Pathogenic Organisms?

Two papers on this subject have lately appeared. One by Dr. FROMM and the other by M. VALLIN. In such investigations two methods are applicable. The one is to determine the temperature in different parts of the cooked meat, and this was adopted by M. VALLIN; the other is to place it in or on the raw meat, portions of a culture of a pathogenic organism whose lethal temperature is known, and, after cooking, to determine by experiments on animals if it has been killed, and this was largely relied upon by FROMM. By using fine drawn-out tubes, containing a small portion of a crystallisable organic body whose fusing point was known, and inserting these in different parts of the meat, M. VALLIN got the following results:—The weight operated upon was in each case about 6 lbs. Gigot of mutton, roasted in Dutch oven one hour and ten minutes, at no part was above 59°C., and some parts not even 56°C. Gigot of veal, roasted two and a quarter hours, had all parts above 69°C. Roast beef, roasted one and a quarter hours, had some parts above 59°C., and others under 56°C. Gigot braised for three hours, all parts above 69°C. FROMM used cultures of anthrax bacillus, sometimes spore-bearing and sometimes not. The cooking was only considered complete when the section was no longer reddish nor moist. After cooking, the piece of flesh was cut in two; one part placed in sterile conditions under a bell jar to allow any organisms present to grow, and the other at once examined. In both the subsequent procedure was the same, namely, to scrape the meat both superficially and deep with a sterilised knife, and mix the scrapings with distilled water. This fluid was used for injecting into animals, to prove whether the cooking had removed the virulence. His results are shortly as follows:—

1. Prolonged boiling of animal food is the most certain method of destroying pathogenic organisms contained in it, whether these are spore-bearing or not. 2. Thin slices of beef when grilled, or roasted done in the oven, never attain a temperature sufficient to destroy spores, though, when this method of cooking is continued long enough, it is sufficient to kill the bacillary form. 3. The braising of beef kills neither bacilli nor spores.—*Edin. Med. Jour.*

Distribution of the Meats.

WHEN an interval of over 5 hours elapsed between one meal and the next, Professor IMANUEL MUNK found that the body was forced to consume its own albumen, fat and carbohydrates. Brain workers require food more often and at shorter intervals than do manual laborers, and the different meal-hours of different countries has as much to do with custom as with physiological requirements. He also shows that the common regulation and distribution of the day's food, both as to time for meals and the quantity to be eaten at one meal, though entirely empirical, closely approximates the hygienic and physiological requirements of the human body.—*Zeit. fur Kran.*

Differential Reaction of Woman's and Cow's Milk.

AMONG a series of investigations on the albuminoids of human and cow's milk, URETSKY demonstrates that the addition of ammonia to woman's milk causes a dark red coloration, while on cow's milk no such change is elicited.

According to the amount of ammonia added, the more pronounced is the reaction, the color passing from red to violet on increasing the amount of the reagent; the minimum quantity of ammonia capable of giving a violet tint being a drop of a 10 per cent. solution to 5 c.c. of milk. This reaction

is accentuated by heating the milk to 60°C, while, on boiling, the violet hue is changed to brown.

Perhaps its most practical bearing is derived from the fact that the more intense does the reaction become the greater the length of time after the confinement; thus it might be used with advantage in testing the accuracy of the statements of wet nurses.—*L'Obetrique.*

Women who Smoke.

THE *London Daily Telegraph* says that "the great middle class is smoking the cigarette as unconstrainedly as the aristocratic order, and working womanhood is taking it up to an extent which is certain ere long to attract the attention of those stern moralists who see in even the purchase of a penny-worth of sweets a growing tendency to self-indulgence. Inquiries among doctors, district visitors, tobacconists, and others who are most capable of expressing an opinion on the subject, have brought forward some very curious facts. Nowhere are to be found more inveterate female smokers than in those long streets in the less considered suburbs of 'genteel' residences, rented at from £24 to £30 a year. The clerk or the shopman marries the typist or waitress, and two such couples share one of these houses. The women soon fulfil their modest household duties, they have slight resources in themselves for reading or artistic work, and have very little, indeed, to spend on amusements. And so, alone or in company, they turn to the cheap cigarette, finding in it something at least to deaden the craving for more exciting pleasure. The low price, too, of the cigarette accounts largely for the increase of smoking among factory and servant girls. Thanks to exquisitely ingenious mechanism, by which one cigarette-making machine can do as much in a day as one hundred and fifty girls could turn out, and can produce five hundred finished cigarettes a minute, these are now within reach, not only of the man in the street, but also the boy, who begins, to puff them while still in the infant classes at school. His small sister tries them also. The West End shop-girls 'living in,' on the other hand, scarcely ever smoke, probably because indoors it would be absolutely forbidden, and outside custom is still strong against it. Most convincing proof, however, of all, that smoking is on the increase among the sex, is that the great wholesale manufacturers are beginning to find it necessary to cater especially for female demands. Women, when they smoke for their enjoyment and not merely to puff a cigarette because it is Bohemian and daring to do so, have remarkably fastidious palates, and in the high-class West End shops demand the most delicate and refined cigarettes, when they do not call for cigars."—*N. Y. Med. Rec.*

Permanent Blindness not due to Belladonna—A Physician wins his Case.

THE effect of belladonna upon the human vision was considered in a libel suit which has recently been reviewed by the Appellate Division of the Supreme Court at Albany, New York. The plaintiff in the action was a physician who treated the defendant's daughter for some ailment of the eyes, and in the course of the treatment administered belladonna. The girl subsequently became blind, and her father attributed the loss of her eyesight to the unskillfulness of the plaintiff and his ignorance in giving her belladonna, and thus producing her blindness. The doctor sued him for libel for publishing statements of this purport, and upon the trial a material inquiry was what were the actual effects of administering belladonna in like cases. Every medical witness testified that belladonna would not, and indeed, could not cause blindness in any person. They all agreed that the drug produced a dilation of the pupil, accompanied by a partial loss of vision, but that this was only temporary and the effect would gradually pass away. The proof on this point was so clear and conclusive as to leave no doubt in the mind of the Appellate Court that the unhappy father was mistaken in holding the doctor responsible for the misfortune of his child.—*Med. News.*

THERAPEUTICS AND PHARMACOLOGY.

Wet Sheet in Pneumonia.

"THE most striking example that I ever saw of the use of cold was in the case of a patient suffering from pneumonia, who was dying from hyperpyrexia without anyone knowing it, for it was before the days of clinical thermometers in this country. The patient was under the care of the late Professor J. HUGHES BENNETT, whose boast it was that he had never lost a case of uncomplicated pneumonia since the time that he discarded the old system of blood-letting and began that of simply supporting the patient's strength. One day, on going round, he was a good deal disgusted to find that one of his patients suffering from double pneumonia was apparently about to spoil his statistics by dying. The man was completely comatose, and apparently moribund. It seemed as if nothing could possibly be done to help him; and Professor BENNETT was passing on to the next bed, when a Swedish doctor, named SOOLBERG, who happened to be attending BENNETT's clinic, said to the Professor, 'May I treat the patient, Professor BENNETT?' 'You can do what you like with him,' was the answer. Forthwith SOOLBERG ordered in a big tub of cold water. All the bed clothes were pulled off, a wet sheet was dipped in the water, and the patient was wrapped in it. In a few minutes it was taken off and a second cold sheet applied. How long this went on I do not know, because, like all the rest who were watching the process, I thought that it was useless, and I went away to have my lunch. On going back about an hour afterwards, simply from curiosity to see whether the man was dead or not, I was greatly astonished, instead of finding an empty bed, as I expected, to see the patient lying quiet and comfortable, apparently in an easy slumber, and he went on from that time forward without a bad symptom, and recovered perfectly in due course. So a wet sheet simply wrung out of cold water, put upon the patient for a short time, taken off again, dipped again, and frequently renewed, tends to bring down the patient's temperature."—*Practitioner.*

Treatment of Chronic Constipation by Creosote.

CREOSOTE, according to HOLESTEIN, is an excellent remedy for chronic constipation if given in doses of 7 or 8 drops immediately after lunch and dinner, in a glass of milk, beer, wine, or water. As the dose which is necessary to relieve constipation is different for different persons, it is well to commence with a single drop and to increase the amount by one drop daily, until the required dose is ascertained. Creosote, when administered in this way for several months, will not only relieve chronic constipation but will bring back the appetite, improve the general condition, and clear up the skin. Under its influence the stools become regular, soft and abundant, and are not accompanied by any pain or any sign of intestinal irritation. The drug is supposed to act by neutralising an intestinal toxin which in chronic constipation paralyzes the intestine.—*Med. News.*

Capitol or Tanno-Chloral in Seborrhoea Capitis.

A TWO PER CENT alcoholic solution of this drug, which combines the secrete inhibitory effects of tannin with the antiparasitic action of chloral, was added to water by J. ERMENOFF and used night and morning with excellent results in seborrhoea capitis. The scabs disappeared in 8 to 14 days, the gland secretion stopped and the hair fell less and less until the fall was finally arrested.—*Deutsches Med. Woch.*

THE PRESENT SITUATION OF THE C. D. ACTS QUESTION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It is no easy matter to say what are the present and immediate intentions of the Government of India on this most important question. If we were to review what had been attempted and carried out up till 1892 or 1893, and if we had to write the history of the Regulations for the previous thirty years, we would have to repeat much that has already appeared in these columns from time to time. We have all along contended that a study of the records supplied by Government itself and a careful reading of the instructions issued on this subject must lead the medical mind to regard the efficacy of these Regulations, on purely medical grounds, as extremely doubtful, to say the least of it. We never come across the note of medical success, and there is no single year's figures which unmistakably tell us that substantial progress has been made. And when we embrace in our investigation a succession of years, we are reluctantly compelled to confess that the medical stratagem tightened up and amended, as it has been year after year, reveals a steady advance of venereal diseases. We use the word reluctantly in this connection, for we have no desire to rejoice over any such increase among the soldiers. If the Regulations had been put forward as a purely temporary measure, a stop-gap, until some measure resting on a firmer foundation—medical, political and ethical—had been sought out and elaborated, then until such a measure had been formulated we would have been pleased to have seen some temporary alleviation of those diseases. Just as we have regretfully to see martial law enforced for a brief period, while red ruin stalks abroad, but only for the briefest of periods and to be recalled as quickly as possible, so for a brief period if the case for so vile a measure as the C. D. "Regulations" could be proved, we might endure it. But we would be equally insistent on its speedy removal to give place to some measure more worthy of our high profession and the high civilization we represent.

The "Regulations" were and are opposed to the highest political spirit of our laws. Mr. HERBERT SPENCER in his "Study of Sociology" thus alludes to them: "A popular Government has established, without the slightest hindrance, an official organization which treats with contempt the essential principles of constitutional rule." And later on he adds:—"This Bill which even had there been some urgent need (which we have seen there was not) for dispensing with precautions against injustice, should, at any rate, have been passed only after full debate and anxious criticism, was passed with every effort to maintain secrecy, on the pretext that decency forbade discussion of it; while Mordant cases and the like, were being reported with a fulsome proportionate to the amount of objectionable details they brought out!"

Thus we see that the "Regulations" are hostile to the spirit of the English constitution itself. They are not extraordinary measures. Their course has been a protracted one, and they must be weighed, not in the light of a manufactured panic depending on rash manipulation of

figures, but as embodied in the laws of our land. As such, if they are to gain a permanent place in our laws again, it will never be in the stealthy and underhand manner in which they were first inserted. Any hysterical wail, startling for a time a people not alive to the whole consequences of their action, will not be sufficient to justify them, but it will be necessary for them to meet the closest criticism, and to show that they have something in harmony with the liberty and justice which are the boast and bulwark of our British constitution.

Some one has written that our race is suffering from a fatal paralysis of the sense of justice, and we could have no better example of this than the C. D. Regulations.

In defence of those "Regulations," a plea for the justice of them rests on the theory that in India the prostitute class is an hereditary caste, the members of which have always been and always will be prostitutes. We do not admit that even if this were true, our attitude towards the Regulations should be altered. If for the above reason the Regulations are justified in India, all that would be needful to justify their enforcement in England would be the transportation of companies of women of the prostitute caste to that country. But an easy answer to the above plea is found in this; that the prostitute caste or class is largely recruited from the outside, and is not sustained and propagated by natural increase from births within the caste. It is surprising that medical men versed in the ultimate results of immorality on offspring, would be found expressing such an opinion.

While we have from personal enquiry found that many who have joined this caste have drifted into it as the last resort of the outcast, and that such are drawn from other castes, both Hindoo and Mussalman, we quote from a pamphlet which publishes the result of a systematic enquiry on this very point. The enquiries were made inside the *chaklas*. We cite seven cases:—

- (I). An orphan.
- (II). A young girl sold by her own brother to the *chakla*.
- (III). A Kashmiri, ill-treated by her husband, ran off with another man and sold into shame.
- (IV). A high-caste Brahmin girl found starving and enticed into the *chakla*.
- (V). A girl taken by a sepooy and sold at 11 years of age to sit in the *chakla*.
- (VI). Beaten by her husband; at age of fourteen ran away; seized by policeman, &c.
- (VII). Deserted by her husband; a Britisher took her to his bungalow and after that, the *chakla*. The seventh represents the history of many.

The *chaklas* have to be reinforced from without from time to time or the caste itself would die out. So we see that after all the *chakla* or brothel in India is not filled by any hereditary caste, although on joining such, the dress of the Mussalman and the religion of the caste which they have joined, are conformed to. It is filled by the victimized, the deserted, the deluded and the helpless. A convenient way for a Britisher to get rid of his victim when he has grown tired of her or has to leave the district, is to consign her to such a place; and indeed however much he might wish to be kind, such a place is the usual end of an out-casted woman.

"There have not been wanting many who have advanced the above plan, one which neither on a priori or a posteriori grounds can be sustained.

Again, we must touch for a little on the statistics question. For the bounding on of Government by a select company is based chiefly on the arguments derived from a study of figures. Instead of discussing afresh Indian statistics, let us turn to the history of the Burmese Station of Thayetmyo, and let us follow the Government Blue Books on the subject. We quote from the *Army and Navy Gazette* of 9th April:—"Admissions, 127-5..... The low rate is attributed to the general absence of prostitution among the Burmese." (*Sanitary Measures* 1867-68, page 89). In 1871 disease had been doubled, "notwithstanding the introduction of rules for the registration of women." (*Sanitary Measures* 1871-72, page 131). A year or two later, Thayetmye figures again among stations unfavorably reported on. In 1880-81 admissions in British Burma are 306 per 1,000. Report after report is a chorus of bitter complaint from disappointed officials. Of course, there is always something to blame. The police are ineffective, the women have learnt, somebody is languid in carrying out the measures, they must be pushed with enthusiasm, then they will succeed. Only they never have succeeded.

"The only thing Colonel Wynn himself can claim for them (the Regulations) is that when they were withdrawn, things were worse..... Impose the system and you perhaps gain a momentary improvement by detecting and checking a certain amount of disease, but you demoralize your men and increase the amount of vice, because one recommends it to another as safe and improved. Then suddenly close your hospitals (by way of experiment or otherwise) and stop the measures on which the men have come to rely, substituting for them no other measures of protection, no restrictions on the men themselves, no attempt to create an alteration in their views and habits, and what can you expect? I say you must expect an increase of disease, and a very sharp one at first. But you may expect it to become less marked from year to year, till as the reliance on a partly illusory protection, and the demoralization produced by the disgusting details of the system, die out—and in proportion as active measures are taken for improvement of another kind—you may expect it to give way to a decrease, slow, perhaps, but in its nature progressive and permanent; though we must still allow something for those extraneous causes, which we ought now to be investigating scientifically, instead of blindly recurring to a system, which never was anything but a leaky vessel, and which ended by landing us where we are now."

The proof of the above is seen by studying the figures of 1894, 1895, and 1896. There the increase of 1894 gave way to a decrease in 1896.

And he would be but a sorry specimen of the medical profession who would venture to sustain the theory that the variation is dependent simply on Regulations. As far back as 1886, we find in four stations the numbers 402 per 1,000 and in 3 stations the admissions are 548 per 1,000, and in all the stations Regulations in force.

In an article on "*Les Maladies Vénéériennes dans les Armées Anglaises, Françaises et Russes*," Dr. COMBES points out the great diversities in the numbers afflicted

with venereal in different countries and in different districts, and admits that the prevalence of disease in the French army is closely in proportion, not to Regulations, but "to the laxity of morals and the development of clandestine prostitution." *Le Progrès* of 25th March, in an article denouncing Regulation, remarks that it is just when throughout the greater part of Europe the syphilis is tending to disappear, without prejudice to the public health, that its advocates make use of the fragments of reports and garbled statistics employed by Lord GORDON HAMILTON and certain court ladies to secure a renewal of it.

Surely it is time that deep and serious thought be given both to the figures and to every aspect of this great sex subject.

Again, in India, we are face to face at the present time with the open expressed desire of many to bring in the Regulation of Vice. In the recent movement, two features were added new in themselves and innocent enough, nay plausible, with the view of gliding the pill of Regulation. We hold advisedly and can prove easily that Regulation—and Regulation alone—is the concern of most of those who have tried to promote the re-introduction of cantonment rules.

One of the correctives prescribed with the Regulation prescription was,—"Moral influence." The speech of the Lieutenant-Governor of the Punjab proves this:—"The splendid temperance movement affords precedence for what may be done in other moral directions, and the grand appeal of the Commander-in-Chief to the soldier himself, &c." Up to the present time, while by orders from Simla the periodical examination of women may be resuscitated at any moment, the Simla compounders have left out the corrective from the mixture. Nor are we surprised at this, for a skilful compounder would inform the prescriber that the two were incompatible.

The second feature added by the promoters is for the benefit of those in far away England. It gives the Regulation mixture a nice color. But the nice color can hardly deceive those in India.

In Circular No. 54650 from Government of India, dated Simla, 20th November 1897, under 4 we read:—"The Governor-General in Council is of opinion that venereal diseases should, as far as possible, be dealt with on the same lines as other infectious and contagious diseases."

So also in Appendix, dated Simla, 3rd May 1895, we find "cholera, small-pox, diphtheria, or typhoid fever" slung together as one.

One only requires to analyse the rules to see that the treatment and Regulation are aimed only at venereal diseases, and it is well known that this packing of venereal and non-venereal together took place when in 1889 the Regulations had to be repealed; and it was under this fraudulent cloak that the Regulations were practically carried on until 1892. Our readers need hardly be reminded that in such diseases as typhoid and diphtheria there are practically no regulations or legislation controlling it in banars, and indeed that up to a recent date the presence of typhoid in native humans was by some denied. But the point is this that the ultimate aim of the new Regulations is the "medical examination of women. Without going into a full detailed criticism of

the 25th September, 1895. Considering the following will suffice:—(a) All buildings in which any temporary examination of women, medical officers may make arrangements to carry out their duty to have the examination of women who voluntarily present themselves."

We are, however, glad to note that from the office of the Quartermaster-General in India, the following prohibitions have been issued:—

(a). Prostitutes accompanying regiments or detachments on the line of march and to standing camps.

(b). Prostitutes occupying buildings which are either the property of Government or of the Cantonment authorities.

(c). Persons holding any office or appointment under the Cantonment authority owning or receiving the rents of buildings occupied by prostitutes. While such measures are of benefit, all such measures will prove of no avail to stem the flood of vice which will continue to rise with the re-enforcement of any Regulation measures, and no Sacch Ust or moral corrective will counteract the poison and demoralisation contained in the very heart of them. Regulation can only flourish amidst demoralisation. Thus we can never be other than opposed to a system of which the hygienic perfecting for both sexes has been declared to be utterly impossible. And if possible, it would infer such a quagmire of filth that thinking men would shudder at the thought of what would become of future generations nurtured in so abhorrent and debasing an environment.

As medical men, it is our solemn duty to defend true sex-relationship on which alone any social order can be rightly built, and to oppose any erroneous and unhealthy movement which destroying or weakening the true meaning of sex would transform our nation into a race of Satyrs.

Yours &c., WM. HUNTLY, M.A., M.D., B.Sc.
MUSSEERABAD.

THE VENEREAL DISEASE QUESTION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As Dr. WM. HUNTLY has been kind enough to notice and reply to my letter in your issue of 1st June, I trust that you will permit me to say a few more words on this subject.

Dr. HUNTLY says that he has little hope of convincing me, and in this he is right; for while I have every sympathy with, and admire, the position he takes up, from a practical point of view I can see nothing in his arguments or in the arguments of those who agree with him, which can by any stretch of the imagination be called convincing. I am quite open to conviction by argument, but not by invective or by the cool assumption that God is upon his side, which latter was, by the way, the grand excuse for the iniquities of the Spanish Inquisition, and is the fundamental article of belief with fanatics all the world over.

Dr. HUNTLY's object as well as mine is the prevention of venereal disease, I think we are also agreed that prevention is easier than cure, as far as I can see, we only differ as to the means that are to be employed; and while he is altogether for moral suasion, and the purifying of social culture, I am for force and legal intervention.

Now in favor of my general argument I can adduce the great decrease there has been in England in almost all the infectious diseases since notification and isolation were made compulsory by law, and it is a curious thing that the two infectious diseases, which now cause the highest mortality, viz., measles and whooping cough, do not come under the law.

Legal compulsion has, in every country where it has been put in force, lowered the death-rate from infectious and contagious diseases. It will, in the future, without a doubt, do the same for venereal diseases.

Can Dr. HUNTLY give me a single case where his methods have been tried and proved successful?

I do not hold a brief for the old C.D. Act, nor for the present Act, if these Acts did not perform all that was expected of them; it was, and will be, largely due to faults in their construction and working, for some of which Dr. HUNTLY's friends are responsible; their method is in the first place to prevent the Government framing a perfect measure, and then to find fault with the measure because it is not perfect. It does not follow because the old C.D. Act was not perfectly successful that no other Act can succeed.

Dr. HUNTLY's position appears to me to be a policy of doing nothing, and in my opinion is neither more nor less than encouraging the importation of venereal disease into England.

I regret that through an error I was made to say that some 8,000 cases of venereal diseases are imported every year from India to England, the figures should have been 800, but like Dr. HUNTLY, I do not attach any great importance to the figures, the fact is admitted on all sides that a large amount of disease is imported.

The number invalided in 1896 was 475, but close on 18,849 men went home either on relief or time expired, and we may presume that some of these took disease with them.

When I said that soldiers are treated far more carefully than the same class in civil life, I said exactly what I meant, as long as they are in the service they are treated properly; it is after they leave the army that they become a source of danger to the civil population at home.

Dr. HUNTLY in his usual reckless way endeavours to throw mud at army medical men on the slender grounds that every case of venereal in the army is not perfectly cured; the State, however, does not engage to keep men in the army until they are cured. As soon as a man is unfit for the duties of a soldier, he is discharged, and time-expired men go when their time is up.

We are all agreed that venereal diseases are very liable to relapse and are very difficult to cure, which only brings us back to the preferable method of prevention again.

I ventured to quote two pithy sentences, which give briefly the conclusions of a French writer of large experience on this subject, they go to prove that legislation has the power of checking the worst forms of venereal disease. Dr. HUNTLY calls these sentences "feeble," but I cannot see the applicability of the adjective.

My criticism of the statement that "it lies to a large extent within the power of the individual to avoid infection" is perfectly fair, and is avoided entirely by Dr. HUNTLY, but the reader can judge for himself this is what the

memorial says: "It would indicate the following practical points, which appear to render it impossible to class venereal diseases with other infectious and contagious diseases, for purposes either of prophylaxis, segregation or treatment." (a) With respect to venereal disease, it lies to a large extent within the power of the individual to avoid infection." This is a general statement, and must be taken as such, to maintain that it refers to the soldier only is futile.

As the above is the only instance in which Dr. HUNTLY tries to refute my criticisms of the "Ridiculous Memorial," it is worthy of note as an example of his methods. Dr. HUNTLY says that C. D. Acts cannot prevent crime, but he forgets that they were never framed with this object.

He quotes Lord LISTER to the effect that "it is the fact of prostitution . . . on which the authorities must proceed." Well, is not this the very ground upon which the Government is proceeding?

Does Dr. HUNTLY seriously think that periodical examination of the class of Indian prostitutes is a hardship, and that it involves the gravest moral consequences to the individual?

Does he maintain that the preferable course is to leave them to rot with disease, without any means of cure or alleviation?

He misses my point when I alluded to the dissemination of anti-C. D. literature amongst young girls and innocent persons. I raised no objection to these individuals being educated upon this subject, what I meant was that they were used by unscrupulous people to put their names to memorials of whose contents they were utterly ignorant. I remember on a previous occasion, hearing a young girl ask a medical man in a crowded drawing room what he thought of the C. D. Act. She would hardly have done so had she understood the subject, yet her's was one of the signatures to a large memorial.

Does Dr. HUNTLY argue that, because "medical men go to Regulation countries to study venereal diseases" there is mere venereal in such countries I do not draw the same conclusion; it is simply because these diseases are under better control.

But enough. I have every admiration for Dr. HUNTLY's views in the abstract. My only difference with him is that they are impracticable.

Yours &c, A MEDICAL MAN

—:—

GOVERNMENT DOCTORS AND PRIVATE MEDICAL PRACTICE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following article appeared in the *Morning Post* of the 11th June, and will, I know, be read with intense interest by the thousands of medical and non-medical readers of the *Record*. Here is the article:—

"THE INDIAN DOCTOR."

"The memorial of the Indian Medical Association to the Government of India, which we published the other day, is an exact counterpart of an article which appeared in the *Morning Post* some two months ago entitled 'Where Economy Lies.' The contention we raised at the time is

precisely what the Calcutta Association is now raising, namely, that "the public needs of the inhabitants of large Indian cities, more especially provincial capitals and hill stations, have materially altered during the past ten years, and that in all these centres there is a sufficiency of British medical practitioners, as well as highly-trained and fully-qualified Indian graduates of medicine, to supply the needs of the public, both European and Indian, and that, therefore, the time for withdrawing the privilege of private practice to State-paid doctors has unquestionably arrived." Our article apparently escaped the attention of the medical men, especially those of Mussoorie, whose cause it espoused, or, perhaps, they were waiting for a responsive echo from Allahabad, in which case we can assure them that they will have to wait in vain. So far as we are concerned, however, it does not matter in the least whether Mussoorie looks down-country or up-country for support, because our main purpose in raising the question was to benefit not a particular body of professionals, but the public generally. The financial prospects of the country were then being discussed in the Viceregal Council, and SIR JAMES WESTLAND, though outwardly full of assurance, gave occasional indications of his anxiety over making two ends meet. We pointed out that an increase of revenue, however probable, had many elements of uncertainty about it, and that the only way to make expenditure and income balance was to curtail the former. It is easier to make suggestions than to put them into execution, and we admit that it is not always clear where the pruning knife can be conveniently applied. But for all that economy is possible, and in the Indian Medical Service we have certainly a good field for experiment. We know of no valid reason why a country, which can support its own tradesmen and schoolmasters, its own chemists and lawyers, should be so hopelessly unable to find employment for doctors. The very fact that private medical men are now to be found in almost every big station in India clearly indicates that there is work for them, though the conditions of service may not be entirely in their favor. It is in the power of the Government to readjust a policy which may have been defensible years ago, but which is now entirely out of place in the present circumstances of the country. It is unnecessary to repeat our first article, but we may notice some of the objections which have been raised to the abolition of our big Civil Surgeoncies. One is that all Government servants are entitled to the services of an official practitioner, either free or at reduced rates, and they insist upon having the best men available—a very dog-in-the-manger objection at best. There is no reason to suppose that private doctors would necessarily be bad any more than that Government ones will be good; as we said before, all Civil Surgeons are not clever while some are decidedly the reverse. Nor need we fear that Government servants will have to pay more because the competition for patients in every large city will be sufficiently keen to keep fees within reasonable limits. Besides there is no reason whatever why any particular class of people should be pampered in their demands for this, that, or the other thing. The man who enters Government service now will be equally willing to do so whether he gets free medical attendance or not, so great is the struggle for existence. The same argument

applied to the second objection—that if private practice were prohibited an inferior class of men would enter the Indian Medical Service. Would they? Given, a fair prospect, in life, and we are perfectly certain there would be no deterioration in the existing personnel. Any unprejudiced individual, looking at the conditions of modern life must acknowledge that very few men are in a position now-a-days to decline half a loaf because they cannot get the whole. When London M.D.'s. are content to act as club doctors, it is inconceivable that their sons will refuse the assured prospects of an official career in India simply because some parasites have been withdrawn from it. The man who shook the pagoda tree in years gone by would probably have laughed at the idea that their better educated descendants would be perfectly happy under less fortunate conditions, and it is quite likely that the generation to come will regard us with the envy as we do the one that is past, and withal be content.

"Yet a third objection, which was made to us privately by a medical friend, is that the conditions under which we hold India are such that any reduction in the numerical strength of the Indian Medical Service would be fatal from the point of view of public exigency. That there is some force in the objection at first sight we admit, but it should be borne in mind that as British rule in India grows in years its military aspect must diminish, as civil power tends to increase. We are not thinking of riots and mobs which concern the police more than the military, and which cannot possibly affect a technical discussion such as this, even though their frequent occurrence should serve to remind us of the want of cordial relations between the rulers and ruled. It is to the chances of real war breaking out that the objection specially referred. The obligation of the Civil Surgeon to revert to military duty whenever occasion arises would not, of course, hold with the private doctor, and this might seem a serious objection to his recognition by the Government. It would, however, only apply in the case of a large reduction in the Indian Medical Service, and not to the experimental measure we advanced, which was to abolish Civil Surgeoncies only in the large cities of India. The Indian Medical Association does not go so far as this, for while claiming more work for the private practitioner, it leaves the Civil Surgeon precisely where he is. It seems to us, however, that if the medical administration of a district which nowhere is very onerous, can be conveniently delegated to the skilled members of the Subordinate Medical Service, it would be absurd to allow the dim shadow of a big war to interfere with an experiment from which much good might be gained; neither can we imagine that the abolition of, say, a dozen appointments will materially endanger the military needs of the country or diminish the efficiency of its war footing. Clearly the Indian Medical Association does not go far enough. Our object was to find an opening for those Anglo-Indian youths whose parents, while quite prepared to give them the best available medical training to be had in India, are yet unable to send them to England. Whether they can be utilised in the place of some of the men who now come out from home is surely well worth an intelligent trial."

Yours, &c., M. D.

MURDOCH, 14th June 1898.

HIGHLY PLACED ANGLO-INDIAN MEDICOS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Your issue of the 1st June 1898, "L. M. & S. (Madras)" has omitted from his list a few other "Anglo-Indian Medicos" who have taken high places.

Dr. R. T. TOOLEN, B.A., formerly of the I. S. M. D., now practicing in Rangoon, has British diploma.

Dr. G. GOSPOIN, M.D. of the I. S. M. D., Civil Surgeon in Bombay.

Dr. ROBERT CARROLL, L.M.S. formerly of the I. S. M. D., now Medical Dispenser to H. H. the Nizam and Lecturer in the Nizam's Medical School.

Dr. STARR, formerly of the I. S. M. D., now Surgeon on the West Coast of Africa, has high British diploma.

And among your several lists I have not seen the name of Surgeon-Major R. R. WHITWELL, M.B. (Bengal), who hails from Madras, and received part of his medical education there, brother to the late lamented Surgeon-Major HARRY WHITWELL (Bengal), formerly of the Madras I. S. M. D.

Yours &c., CIVIL SURGEON.

—:O:—

THERMOMETERS. WHY DOES MINE GO WRONG?

TO THE "EDITOR, INDIAN MEDICAL RECORD."

Sir,—When I was going to take the temperature of a patient of mine with fever, I found the clinical thermometer, when taken out of my own pocket, read 102°. Before applying it to the patient I placed the bulb in cold water and set the temperature at 0. Just as I was going to place it in the patient's axilla it again rose to 102°. It was therefore useless to try the same process over and over again. Will you kindly tell me what to do on such occasions? I have seen this occur before too.

Yours &c., JAISHAN DAS, L.M.S.

Assistant Surgeon, Sonapat.

SONEPAT, 7th June 1898.

Book Reviews & Medical Trade Notices.

FIFTY-FOUR CONSECUTIVE OVARIOTOMIES WITH FIFTY-THREE RECOVERIES.

By A. C. BUTLER SMYTHE, F.R.C.S., F.R.C.P.

Senior Surgeon to the Grosvenor Hospital for Women and Children, London, and to the Samaritan Free Hospital for Women and Children, London.

(Publishers: J. and A. CHURCHILL, London).

THIS record of 54 ovariectomies affords very interesting reading of remarkably successful abdominal surgery. The fourth case died, but it was one in which septic changes in an ovarian cyst had already done their work of desperately hazardous life. After this case, there is a run of 50 absolute successes. A careful perusal of the clinical features of all the cases proves that there has been no attempt at sifting, but that each patient was allowed to take her chance of life, when once it was decided that an operation would do her good. To surgeons in India this measure of success is extremely enviable and most extraordinary. Hence a few details concerning Dr. BUTLER SMYTHE'S methods will not be out of place. Most of the operations were performed in the Grosvenor and Samaritan Hospitals in London, and some in private houses. Dr. BUTLER SMYTHE attributes his success to surgical asepsis, rather than to anti-asepsis. The older methods of carbolic sprays, medicaments, the sealing of wounds by carbolic putty, the toilet of the peritoneum by means of sponges impregnated with carbolic acid, the great masses of carbolic and other medicinal gauzes, have all been laid aside as irritating and unnecessary. He says, "aseptic surgery has proved beyond dispute that perfect cleanliness, before 'at and after' operation, is the great essential for the welfare of the patient." Dr. SMYTHE prefers 9 A.M. as the hour for operating.

The room should be well lighted, scrupulously clean, and far removed from water closets and bath-rooms. It should contain two beds, a cupboard, wash-stand, two tables and two chairs. It should be fumigated with sulphur fumes just prior to the operation. No eatables should be kept in the room.

She should have some experience of abdominal surgery. She should be efficient in the use of the catheter, and understand rectal feeding and the use of enemas. She should know how to take brief clinical notes, and she should above all things be implicitly obedient and trustworthy.

The preparation of the patient is important. As a rule, she is kept under observation for a few days, special attention being paid to the state of her bowels, kidneys and skin and all errors corrected. Her diet is nonstimulating and she is allowed to be calm and quiet for a few days. The bowels are cleared by an aperient a day before the operation, and on the morning of the operation an anæmia is given. Only a small cup of strong beef tea is allowed four hours before the anæsthetic, and if there is much debility, a little brandy and water is permitted. The bladder is emptied by a catheter. A light night dress and warm stockings are to be worn.

The operator should trust no one but himself with the scrupulous care of his instruments and sponges. He should have all he requires by his side, and he should make a written note of everything he is going to make use of.

For an ovariectomy one needs fifteen sponges, (two flat six large, six small, and one for the hands). There should be at least two dozen Spencer Wells' forceps. When the operation is finished, the sponges and instruments ought to be checked, while the nurse counts them out aloud.

This thoroughly practical operative experience is worth close and attentive perusal, and will serve as a very useful help to surgeons who are keen on practicing abdominal surgery in India.

URDU HAND BOOK FOR MIDWIVES

By Miss E. M. BROWN, M.D.

This excellent little manual ought to prove a most useful and opportune prize to native midwives or *dhais*, for whom it is expressly written. The need for such a guide is and has been keenly felt in India, both in the women's hospitals where this useful class of trained nurses are situated, and also among the greater army of untrained. Of course neither of these classes will be aided by this book, save through the instrumentality of native teachers who can read English and are accustomed to read Urdu in Roman character. We congratulate Miss Dr. BROWN on her successful output of this useful little book, and would strongly advise its translation into the real vernacular of India, as it possesses all the merits of a very trustworthy hand-book for midwifery nurses and is well illustrated. We note the diagrams have been taken from Dr FANCOURT BARNES' Manual for Midwives by his permission.

The book may be had from the Mission Press, Ludhiana, Punjab.

DISEASES OF WOMEN.

By J. C. WEBSTER, B.A., M.D., F.R.C.P.

Demonstrator of Gynecology, McGill University, Montreal, Canada

(Publishers YOUNG & PENLAND, Edinburgh)

Gynecology has been enriched by the publication of this work. It is a concise, practical, up-to-date monograph, profusely illustrated and very well got up.

THE PASTEUR (CHAMBERLAND) FILTER.

WHAT THE BATTLE OF ATTHARA WAS WON ON.

STATEMENT BY LORD CROMER.

Daily News, April 16th, 1898.

The annual meeting of the Society for the Study of Inebriety was held on Thursday afternoon in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, Dr. NORMAN KERR, the President, in the chair.

Lady ELIZABETH BIDDLE had the pleasure of celebrating a fact which had not yet appeared in the press—winning the splendid victory won by our troops on Good Friday morning at Athara. She was in Cairo at the time that our soldiers left for the Athara camp. All of a sudden there was a whisper went round among the wives and other friends of the military men to the effect that the Sirdar (Sir HERBERT KITCHENER) had sent back all the beer that had been ordered to the front with the soldiers. Being a supporter of the cause of temperance, she was naturally interested in this move, and on making inquiries ascertained that, as far as possible, all intoxicants were to be excluded during the campaign. In a conversation which she had with Lord CROMER on the subject, he said that if beer was allowed in the camp, he was afraid there might not be as much work done. "But what about the Nile-water?" she asked.

"WE HAVE PASTEUR FILTERS IN THE CAMP,"

was the reply, "and plenty of good tea and coffee, which you will find our troops will be able to fight on." They had fought, and what was the result? A great temperance as well as a great and brilliant military victory. (Applause.)

Sole Agents for India HEATLEY & GREENHAM, Ltd.

STEARNS' HÆMOFERRUM.

As a food hæmoferum is far richer in proteid matter and iron than the finest brands of beef juice on the market. Owing to its digestibility and the readiness with which it is absorbed, it is of special value in cases where the digestive organs are enfeebled and the problem is to give food. A small amount of readily absorbed and easily assimilated food taken at the right time is a more powerful restorative agent than a whole meal of undigested material which only adds to the mischief by its fermentation and formation of toxins.

It should be borne in mind that the effects of iron differ according to the dosage. Hæmoferum has great advantages on account of the ease with which the dosage may be regulated.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

The services of the undermentioned officers are replaced at the disposal of the Govt of Punjab from dates on which they respectively assumed charge of their duties—Surgn.-Capt. H. Smith, M.D., M.C., I.M.S. (Beng.); Surgn.-Capt. G. Y. O. Hunter, I.M.S. (Beng.)

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTH.

BRAGANZA—On the 22nd June, at Karachi, the wife of Surgn.-Maj. M. B. Braganza, 80th Bombay Infantry, of a son.

MARRIAGES.

HINDLEY—TYLER—On Sunday, the 1st May, at Southampton, Godfrey Douglas Hindley, B.A. Oxon, M.B.S., L.R.C.P., of 69, Queen's Road, N.E., to Alice Evelyn, eldest daughter of Sir John Tyler, M.D., C.I.E., of 25, Hanover Square, W.

RUDDUCK—TAYLOR—On 10th May, at St. Peter's, Bayswater, by Rev. E. W. Moore, assisted by the vicar of the parish, John Burton Rudduck, L.R.C.P., M.B.S., late of Assam, to Maude Mary Perston Taylor, late of Bethlehem and Morocco, eldest daughter of Robert Taylor, Solicitor, of 7, Bedford-row, W. C.

LINDSAY—FOWLER—On Monday, the 6th June, at Trinity Church, Karachi, by the Rev. A. Howard, M.A., Victor Edward Hugh Lindsay, M.B., Ch. B., Surgn.-Lieut., I. M.S., third surviving son of the late Frederick Lindsay, M.A., J.P., D.L. Barrister-at-Law, of Loughry, Co. Tyrone, to Helen Frances Levine, eldest daughter of Major W. Merrick Fowler, late 61st Regiment, of Strode Manor, Dorset.

DEATHS.

IRVING—On 3rd May, at Royal York Crescent, Clifton, Bristol, Surgn.-Genl James Irving, M.D., Bengal Army (retired), aged 75 years.

LE MOTTE—On the 5th June, at Quetta, Beluchistan, Herbert De Lisle, beloved son of Surgn.-Lieut.-Col. G. H. Le Motte, A. M. S., aged 15 months.

NOTICES TO CORRESPONDENTS.

M. R. L. (Mylavaram).—For the case you describe, the fee for a Hospital Assistant's attendance on a patient in good circumstances at a station four miles distant ought to be ten rupees for each visit and travelling expenses paid.

F. V. (Solapur).—If the patent is in good circumstances, and if you have been in attendance for two months, a fee of Rs. 500 for a man of your professional position would be a very fair charge.

F. C. R. C. (Mandalay).—Your suggestion is a good one and will be kept in view when the next representation is made to Government.

K. M. Y. (Madras).—The memorial of the Indian Medical Association is now before the Government. Your letter has been filed for future reference.

H. K. S. (Raiganj).—In a later issue.

T. D. (Hartkint).—On trial.

A. J. H.—You will get full information in the new edition of the *Medical Register and Directory of the Indian Empire*.

INDEX

TO THE

INDIAN MEDICAL RECORD.

VOL. XV.

JULY TO DECEMBER 1898.

A.

A clean sweep, 338.
A College! A College!! A College!!! 475.
A determined student, 30.
A grave scandal, 383.
A little war anecdote, 208.
A. M. S. and I. M. S. Present strength of the, 113.
A. M. S., its past services and its present needs. The, By Peter Alex. Young, M.D., 181.
A. M. S. in its new colors; how do they look? The, 275.
A poor man's very hard case, 217.
Abdominal reflexes in gynecology. Diagnostic value of, 120.
Abdominal operations. Shock after, 265.
Abdominal or vaginal route in intra-pelvic surgery, 305.
Abdominal section performed a second time in 26 cases. By John D. Malcolm, M.B., 357.
Abortion. Complete inversion of the uterus following, 33.
Abortion. Spurious, 119.
Abortion due to quinine. By Assistant Surgeon Balagopal, I. M.S., 284.
Abortion. Self-induced instrumental, 423.
Abortifacients and criminal abortion. The sale of, 157.
Accident to the Prince of Wales, 157.
Accountability of the physician. The, 348.
Acute poisoning, 337.
Administration of the Indian Medical Department by civil service secretariate, 176.
Administration Report of the Commissioners of Calcutta for 1897-98, 328.
Advertisements. Indecent, 297.
Advertisements. Some more compromising Calcutta Medical, 489.
Advertising doctors, 519.
Advertising in Lucknow, Medical, 582.
After 19 years' service: No blessing at all, 401.
Alcohol. A medical speech on, 27.
Alcohol as a causative factor in disease of the central nervous system, 117.
Alcoholic meningitis. Treatment of, 392.
Allenbury foods. The, 85.
Almost buried alive? 423.
American bequest. A handsome, 30.
American-Spanish war. The, 71.
American Independence. The famous declaration of, 158.
American drinks. Three, 309.
An Ambulance ship. 80.
Anemia. Red bone marrow in, 344.
Analysis of air. 109.
Analysat analysed. An, 203.
Anatomy of the anus. 84.
Aneurism of the palm. Circumscribed, By Arnold Caddy, F.R.C.S. 412.
Aneurisms treated by subcutaneous injections of gelatine, 473.
Angina pectoris; its diagnosis and treatment, 433.
Anglo-Indian Cause at Muncorie. The, 29.

Anglo-Indian Cause. The, 72, 81, 156, 489.
Anglo-Indians. Highly placed, 41, 88, 311.
Anglo-Indian successes, 72.
Anglo-Indian problem. One view of the, 112.
Anglo-Indians and the Irish cause. 113.
Anglo-Indian Question. The whole aspect of the, 162.
Anglo-Indian Association. President Pugh's views and opinions on the Imperial, 198.
Anglo-Indian *versus* British plague doctors and nurses. 200, 201, 211.
Anglo-Indian nurses. The London "Nursing Record" on, 382.
Anglo-Indian Conference at Allahabad, 385.
Anglo-Indian loyalty, 440.
Anglo-Indian medical women, 520.
Annual Meeting of the British Medical Association. Sixty-sixth, 26.
Annual report of the Sanitary Commissioner with the Government of India, 55.
Annual report of the Sanitary Commissioner for Bengal for 1897. The thirtieth, 466, 508.
Anomalous medical pensions, 176, 180.
Anti. To my, 71.
Anti-opium crusade in India. 71.
Antipyrin for diagnosing kidney diseases, 448.
Anti-seborrhoeic hair-wash, 269.
Anti-streptococcus serum in primary venereal sores. By James Moore, F.R.C.S. 501.
Antitoxin. Patent. 297.
Antitoxin dead at last. 298.
Antitoxin poisoning, 396.
Apoplexy. Temperature relations in, 391.
Appendicitis, 206, 265.
Appendicitis. Notes on, By Albert Carless, M.S., F.R.C.S. 403.
Appointments of a staff nature distributed to Military Assistant Surgeons, 310.
Appointments. Calcutta Medical College, 338.
Army Warrant Medical Service. A new departure for candidates for the, 520.
Aromatic toilet vinegar. 37.
Aromatic essences in puerperal infections, 119.
Aromatized codliver oil. 87.
Arthritis in childhood. By Geo. F. Still, M.D., 453.
Aseptic glass catheter cases. 85.
Asepsis of towns and dwellings, 121.
Asepsis. Failure of midwives in, 171.
Asepsis in operative surgery, 207.
Asphyxiated child. New method to restore an, 208.
Aspiration treatment of inguinal bubo, 33.
Asthma powder, 397. 525.
Auscultation of the mouth, 32.
Auto-intoxication, 157.

B

Baby. First care of a, 71.
Babe's new treatment of tetanus etc, Professor, 375.
Bacilli of ber-berl, 67.
Bacilli and sewer-gas, 396.

- Bacteriology of infantile diarrhoea, 306.**
Bacteriology. Kitchen, 309.
 Bacteriology with reference to plague, 392.
 Bacteriological find punctured. The, 87.
 Bacteriological laboratories in India, 357.
 Bad training in Indian Medical Schools, 355.
 Bahadurji. The death of Dr. K. N., 302.
 Balfour on medical research. Mr., 158.
 Barber shop. A sanitary, 437.
 Barrackpore murder case, *Medical-legal aspects of the*, 154.
 Baths in various diseases. Warm and cold, 849.
 Bay-rum, 80.
 Beechwood creosote in phthisis, 523.
 Beginnings of mental life, 120.
 Belly band. The, 846.
 Beri-beri. The micro-organism of, 111.
 Betal-ol (Kuhn) 88.
 Bicycle and gynaecology, 77.
 Biocyla. Contra-indications for the, 252.
 Bile-ducts. Suture of the, 845.
 Bile pigment. Very delicate test for, 394.
 Bismuthide of mercury as a substitute for Potassium Iodide, 80.
 Biologic differences between the bacillus of Eberth and the.
 Bacillus coli, 85.
 Biomechanics of the circulation, 173.
 "Black list" How to keep a, 296.
 Blisters. Dangers of, 369.
 Blood examinations. Current methods of, 436.
 Blood-letting as a therapeutic agent. By Bela Cogahali, M.D., 183.
 Blood reaction in diabetes, 117.
 Blood coagulation in living tissue, 78.
 Boils, 123.
 Bombay. Health of, 69.
 Brain. Blot upon the, 307.
 Brain tumours. Differentiation of, 345.
 Bread. Peculiar adulteration of, 268.
British Medical Journal in hysterics. The, 114.
 Bromides. Unexpected effects of, 210.
 Bullet wounds. By Surgeon-Major W. C. T. Poole, M.B. 14.
 Bullet extracted from the brain with the help of the Röntgen rays, 76.

C.
 Calcium sulphide as a depilatory, 210.
 Calcutta General hospital, 312.
 Calcutta Professors' qualifications, 380.
 Calomel in typhoid fever, 396.
 Cameron on typhoid fever in connection with soil contamination. Sir Charles, 381.
 Can Companies carry on medical practice, 28.
 Cancer a contagious disease, 76.
 Carbolyzed adhesive plaster, 86.
 Carbuncle associated with diabetes—By Anthony Fr. Fernandes, C.M.S. 245.
 Carbuncle. On the treatment of, By Thomas H. Manley, M.D. 493.
 Carcinoma, Primary pleural, 436.
 Castor oil. Palatable emulsion of, 123.
 Castration. Undescended testicle, going rise to distressing symptoms due to sarcomatous degeneration. By James R. Wallace, M.D. F.R.C.S.I. 190.
 Castration and Vasectomy in hypertrophy of the prostate, 206.
 Catarrh. Benile uterine, 436. 435.
 Catarrhal jaundice, 589.
 Cataract operations. Recent experiences with, 76.
 Cataract. Remarks on the surgical treatment of, By Ernest F. Neve, M.D. F.R.C.S. 281.
 C. D. Question. On the, 83.
 C. D. Act in India. The, 83, 111, 175, 212, 273, 397.
 C. D. Act. The fallacies of the supporters of the, 356.
 Cellulitis. Severe pelvic suppurative, By Assistant Surgeon J. O. Gillmon, L.S.A. 412.
 Cerebro-spinal fever. By Colonel R. C. Saunders, I.M.S., 284.
 Chemists be careful, 386.
 Chicago Independent Medical College in Bombay, 426.
 Chloroform anaesthesia. The production of, By Surgeon Lieutenant Colonel Edward Lawrie, I.M.S. 85.
 Chloroform narcosis. Extract of suprarenals as a stimulant in dangerous, 118.
 Chloroform. Examination of, 349.
 Chloroform accident. A curious, 356.
 Cholera. Treatment of, 40.
 Cholera infantum. Subcutaneous injections of serum in, 364.
 Cholecystic gastrotomy, 304.
 Circumcision. Origin of, 76.
 Civil Assistant Surgeons and their newly gazetted prospects, 125.
 Civil Assistant Surgeons of Bombay. The, 311.
 Civil Assistant Surgeons. Improving (?) the prospects of, 312.
 Civil Assistant Surgeons. Future position and prospects of, 370, 384.
 Civil Assistant Surgeons are not subordinates, 531.
 Civil plague medical officers, 64.
 Civil Apothecaries and their grievances, 271.
 Civilized manners for the medical practitioner, 114.
 Climatic treatment, 199.
 Ollmacterium in males, 306.
 Cobra-bite treated with tobacco ash, By Tricamal Mayanall, C.M.S. 245.
 Cocaine. Death from, 122.
 Cocaine in surgery, 265.
 Coley's fluid in inoperable tumour, 76.
 Collins' case. The, 160, 194.
 Collins' trial. The sequel to the, 385.
 Colles' fracture of the radius, 196.
 Colles' law, 462.
 College fees, 273.
 Colonisation of the tropics by white men. The, 413.
 Coma. Varieties of, 31.
 Comfort and cleanliness. By Catherine Buckton, 314.
 Communication of syphilis a crime. The, 26.
 Conference at Allahabad. The coming, 528.
 Confidential reports. The tyranny of, 441.
 Conjunctival affections treated by Argentamin, 392.
 Constipation. Treatment of, 304.
 Constipation with acne, 349.
 Constituent of the suprarenal capsule which raises blood pressure, 78.
 Contagious Disease hospital. Decision favorable to a, 173.
 Contagious diseases. Insects and the transmission of, 347.
 Convulsions in infants and children, 303.
 Cookery as a branch of medical study, 28.
 Corn salvo, 80.
 Corne. Death to, 525.
 Cornea. Some causative factors in ulceration of the, 208.
 Corneal ulceration and abscess, 143.
 Cough. Spasmodic, 174.
 Craniotomy combined with podalic version, By R. Strinivasa Pillay, C.M.S. 413.
 Cream embrocation, 87.
 Creosote. How to administer, 122.
 Croupous rhinitis, 119.
 Cunningham. M.B., F.R.S., Professor D.D., 109.
 Curette after abortion and delivery, 495.
 Cyst of the Pancreas, 76.

D.
 Dangers from intermarriages, 35.
 Dargal. Brief notes of the treatment of natives wounded at, By Surgeon-Colonel J. Davidson, 97.
 Dead twin retained till full term, 77.
 Death from antonia, 36.
 Death of an old Indian doctor, 158.
Ducann Medical Journal. The, 476.
 Defecation in infants. Difficulties of, 267.
 Definition of medical practice, 29.
 Definition of the "pathies" 336.
 D. G. Our worthy, 476.
 Delirium tremens. Treatment of, 205.
 Dentition. Powder for difficult, 125.
 Deserted cities of the future, Bombay and Madras, 285, 387.
 Diabetes diagnosed from stained specimens of the blood, 75.
 Diabetes completely cured. By Professor Pietro Lépore, M.D., 93.
 Diabetes Mellitus. Varieties of, 303.
 Diabetes Mellitus. Uranium nitrates in, 309.
 Diabetes and paralyis. General, 392.
 Diabetes. Spermin in, 397.
 Diabetes. Conjugal, 523.
 Diabetic albuminuria and its treatment, 169.

Diabetic foods. Chemistry of, 313.
 Diamond cut diamond, 113.
 Diarrhoea due to ascaria. Fatal, By Surgeon-Major R. E. Wastler, I.M.S., 345.
 Diarrhoea and dysentery, 397.
 Diarrhoea in children treated with sterilized water, 482.
 Dias of Hyderabad Dr Mathew, 127.
 Diet in Insbriety, 308.
 Digestion of children, 172.
 Dika fat, 80.
 Diphtheria and Rhododendron, 122.
 Diphtheria. Sero-therapie of, 152, 268.
 Diphtheria. Chronic, 170.
 Diphtheria successfully treated by the topical use of citron juice, By Assistant Surgeon E. S. Fushong, 244.
 Diphtheria. Statistics of the serum treatment of, 349.
 Diphtheria. Heart complications in, 481.
 Diptheria antitoxin per os, 522.
 Diploma of the Apothecaries' Society. The, 114.
 Diplomates of the Calcutta Medical School, 428.
 Diseases of the lungs. The, By J. K. Fowler, M.D., 218.
 Diseases of women. By J. O. Webster, M.D., 218.
 Diseases. The cause and susceptibility to, 515.
 Disinfection of rooms, 524.
 Disorders of digestion in infancy and childhood. By W. Soltan Fenwick, M.D., 217.
 Distemper of dogs as a cause of puerperal fever, 34.
 Diuretic wine, 397.
 Doctors' parasites, 295, 296.
 Doctors and doctoring, 336.
 Doctor and clergyman, 427.
 Doctor and the State. The, 468.
 Domiciled British and European Community of India. The Socio-political position of the, 471.
 Drinkers. Moderate, 395.
 Duboisin. Indications for and against the use of, 122.
 Dyspepsia, Nervous, 169, 174.
 Dyspepsia. Recent views on, 264.
 Dyspepsia with flatulence, 269.

E.

Earache as a preliminary symptom of lock-jaw. Dr. Lukman-ud-Dowlah, on 462.
 Eclampsia. Pathology of, 455.
 Ectopic gestation. Treatment of, 435.
 Eczema. Buckskin dressing for, 36.
 Eczema. Alkaline treatment of, 487.
 Eden Sanitarium, Darjiling. The, 278.
 Editorials:—Administration report of the Commissioners of Calcutta for 1897-98, 828—Advance of Medicine in India and the I.M.S., 99—Annual report of the Sanitary Commissioner with the Government of India, 55—Atypical malaria as seen coming from our military hospitals, 416—Babies' new treatment of tetanus, rabies and other nervous diseases, Professor, 375—Civil Assistant Surgeons and their newly gazetted prospects, 195—Collins-Uniell case: its lessons and warnings, The, 194—Colonisation of the tropics by white men. AN ANSWER TO MR. LEONARD HILL'S
REJOINDER REGARDING THE
HYDERABAD COMMISSION.*

Dr T. LAUDER BRUNTON, M.D., F.R.S.,
Physician to St. Bartholomew's Hospital, London.

In his rejoinder¹ to my reply,² Mr. LEONARD HILL takes up a curious position; for on the one hand he says that he regrets exceedingly that vigour of criticism should be regarded by Dr. LAUDER BRUNTON as a personal offence, and on the other he says, "The strength of my attack is justified to the full by Dr. BRUNTON's statement that he stands alone responsible for the work of the second Hyderabad Commission."

These two statements are so contradictory that the only conclusion I can come to is that Mr. LEONARD HILL does not know himself what he means, but I am quite willing to believe that he does not see the whole gravity and scope of his accusations, and I shall therefore pass over their personal bearing, and confine myself, as far as possible, to their bearing on the character of the work of the second Hyderabad Commission, which, being more important than the first, is usually simply called the Hyderabad Commission. I have already explained in my reply how I came to be responsible for any deficiencies in the work of this Commission, but I am very far indeed from claiming the credit for the work actually accomplished, which belongs to the Commission and not to me individually.

It is obvious, however, that as I am so far responsible for the work, any accusations brought against it are really directed against me personally, whether they were intended to be so or not, and the duty of answering them devolves upon me rather than on any other member of the Commission.

Before proceeding to examine the arguments by which Mr. LEONARD HILL, in his rejoinder in the *British Medical Journal* of 19th March, attempts to support the accusations he brought against me in the *Journal* of 17th April 1897, I will endeavour to correct some misapprehensions under which he appears to labor (a) in regard to the constitution of the Hyderabad Commission, and (b) in regard to my reason for mentioning the shortness of the time occupied in the work.

(a) In his rejoinder Mr. HILL asks: "Were Surgeon-Lieutenant-Colonel LAWRIE and Dr. LAUDER BRUNTON the first and second Commissioners respectively, and the Commissioners BOYFORD, ROSTOMJI, HENRI, KELLY, CHAMARSETTY merely assistants?" Mr. HILL appears not to have read with care the report which he has so violently attacked, for otherwise he would have known (1) that, so far from Surgeon-Lieutenant-Colonel LAWRIE being the first Commissioner, he was not even a member of it; and (2) that the second Commission continued its work during my absence through illness, which it could not have done had I been the Commission instead of being merely a member of it.

(b) Mr. HILL asks why my three months' ticket was not extended? The answer simply is that I could not be absent longer from my engagements in London and accept-

ed the invitation to join the Commission only for this limited time. But Mr. LEONARD HILL completely misapprehends my meaning when he says: "It is a curious excuse to bring forward in defence of deficiencies that the work of scientific investigation was done in a hurry." He does not appear to understand that there is all the difference in the world between doing things quickly and doing them in a hurry, for this term implies a want of the complete co-ordination of action requisite to obtain the best result.

The scientific work of the Commission was done in a short time, but it was not done in a hurry, and I have not brought forward hurry as an excuse for any deficiency in the work done by the Commission, with one exception, which I will presently mention, and which I ought to have specified in my reply. Notwithstanding the shortness of time allowed for collecting apparatus, I was able, either by purchase or by selection from what I possessed, to obtain all the instruments I thought necessary, with one exception, namely, LUDWIG and VON BASCH's electrodes, those which I have had in my possession for many years, and used in former researches, were unfortunately mislaid, and I was unable to obtain new ones before sailing. The electrodes I had with me were such as had been generally in use by physiologists previous to 1874, and are quite sufficient for most work, although the possession of LUDWIG's electrodes would have ensured more perfect application of the stimulus to the vagi than was attained in Experiment 95. As a doubt regarding the application of the stimulus was carefully mentioned in the report, the record of the experiment was perfectly trustworthy, and affords no ground for Mr. HILL's objections. With this exception my mention of the shortness of time employed in collecting apparatus, and in the work of the Commission was not brought forward by me as an excuse for any imperfections in the work actually done and recorded in the report. It was intended as an excuse for the work which the Commission, in spite of the other advantages at its disposal, was obliged to leave undone, and which is therefore altogether outside Mr. HILL's criticism. The work of the Commission has been supplemented by the researches of GASKELL and SHORR, and also of HARR and THORNTON, both of which researches were initiated by Surgeon-Lieutenant Colonel LAWRIE. Yet much remains still to be done, and some of the lines of research on which the Hyderabad Commission worked are still in the same state as it left them. The Commission began to investigate the influence of altered tissue change and excretion on the susceptibility of the cardiac nerves to stimuli, and on the production of shock either with or without chloroform, but this question still remains to be worked out, although a new research by CYON on the effect of thyroid extract upon the excitability of the cardiac nerves gives reason to hope that our knowledge regarding this subject may soon receive a substantial increase.

Having now tried to correct Mr. HILL's misapprehensions, I will proceed to examine the arguments by which he endeavours to support the accusations of (1) prejudice, (2) carelessness, (3) ignorance of scientific methods; and (4) incompetence, which he brought against me in the *British Medical Journal* of 17th April 1897. In his rejoinder he says: "I never intended any attack that I have made upon the conclusions of the Hyderabad Com-

* Reproduced from the *British Medical Journal* by request.

decision as a personal attack upon Dr. LAUDER BRUNTON, for whose work I naturally have the highest appreciation." But the attack now in question was made by Mr. HILL not upon the conclusions of the Hyderabad Commission, but upon their experimental work. Their conclusions might have been wrong, and yet the experimental work perfectly right. But Mr. HILL has chosen to deny the trustworthiness of the experiments, and thereby he attempts to nullify the whole work of the Commission. In his rejoinder he does not withdraw his accusations, but on the contrary tries to substantiate them. In order to justify this action he must prove his accusations to be true. I shall now take them up *seriatim*, and examine the evidence by which he attempts to prove them.

1. His first accusation is that of prejudice. In his lecture, he said the "Hyderabad Commission engaged on a wild goose chase to prove that the respiration ceases before the heart failed." In my answer, I mentioned my responsibility in connection with the work of the Commission, and showed that when I set out for India, any prejudice that I had was in favor of danger arising from the direct action of chloroform on the heart, so that when the results of many experiments caused me to change my opinion, the announcement was mentioned by *The Lancet* with a certain amount of surprise in the annotation which I quoted in my reply. In his rejoinder, Mr. LEONARD HILL simply gives a short historical summary of the appointment of the Commissions which has no apparent bearing on the subject, and then quotes from a leading article in *The Lancet* the following passage— "Clinical experience and physiological experiments have led to the conclusion that it (chloroform) has a paralysing effect on the heart, while ether exerts such an action in a very minor degree, if at all. It is almost impossible to believe that the conclusion at which European and American surgeons and scientists have arrived is, after all, destitute of foundation, and little better than an idle dream." It was because this passage exactly expressed my opinions on the subject when I left England that *The Lancet*, in the annotation to which I have already referred, expressed surprise at the change they had undergone, and anxiety to learn the experimental evidence which had induced this change. Had any further evidence been wanted to show how utterly groundless Mr. LEONARD HILL'S accusation of prejudice was, the quotation which he himself gives in his rejoinder would supply it.

2. His second accusation is that of carelessness. This charge is of the very gravest kind, for if it be true, it entirely deprives the experimental work of the Hyderabad Commission of any value whatever. So important is it that I shall again quote it. Mr. LEONARD HILL says in his lecture that the conclusions of the Hyderabad Commission were "upheld by a series of experiments, many so careless in their execution that they could not for one moment be accepted by a trained physiologist." Although Mr. HILL only states that many of the experiments made by the Commission are untrustworthy, yet he practically condemns every one of them as utterly valueless, for, as his accusation at present stands, it is impossible to bring forward a single one of the Commission's experiments without being liable to the retort that it is one of the "many" which Mr. LEONARD HILL has declared to be so careless in execution

that they cannot be accepted. If his accusation be true, the most conscientious research made on the action of chloroform is nothing more than a complete and useless waste of time, labor, animal life and money. It is evident that these charges are of the gravest nature, and before making them Mr. HILL ought to have been certain that he could prove them by incontrovertible evidence. Let us now see what the evidence is which he actually brings to support them. It is of such an extraordinary character that I shall quote part of it verbatim. He says:—"In justification of my charge of carelessness I can bring forward the following facts:—

"(1) That the work of the first Commission was conducted by men unskilled in experimental methods and apparently without apparatus,

"(2) That the second Commission was conducted in an out-of-the-way place with such apparatus as could be hurried together in the fortnight preceding Dr. BRUNTON'S departure.

"(3) That the research was hurried through in forty-seven days.

"(4) We may turn to the internal proof to be drawn from the experiments themselves.

"(a) An absolutely insufficient method was used to record the energy of the heart.

"(b) That chloroform was injected into the jugular vein, and was not washed on into the heart by normal saline solution. Thus no syncope occurred."

From this quotation we see that the first proof Mr. HILL brings forward in support of an accusation of the utmost gravity, which, if true, would utterly destroy the value of all experiments done by the second Hyderabad Commission, and for which I am responsible, is that these experiments were careless in execution because the first Commission, which sat nearly two years previously, and of which I was not a member, "was conducted by unskilled men and apparently without apparatus." A more remarkable *non sequitur* it would be hard to find.

His next proofs are, if possible, still more extraordinary. Mr. HILL lays down a standard of his own, by which he judges our experiments and condemns them as careless, whilst he appears to be ignorant of the meaning of the term. He seems not to know that carelessness does not depend on the place, where a thing is done, on the apparatus with which it is done, nor on the time employed in doing it, but on the way in which it is done. It is a term quite inapplicable to place, materials, or time, and applies only to the manner in which the operators employ the means at their disposal. If Mr. HILL'S standard of carelessness were correct, we might at once cast aside as worthless all the observations of travellers or exploring expeditions because they have been made in out-of-the-way places. Henceforth civilised Governments may save themselves the trouble and expense of sending out expeditions to observe the transit of Venus or total solar eclipses because any results they obtain will, according to Mr. HILL'S canon, be condemned beforehand as absolutely untrustworthy, inasmuch as the observations must necessarily be made (1) in out-of-the-way places; (2) without the aid of such large telescopes or such perfect apparatus as would have been available at home; and (3) in a space of time which has to be measured by seconds,

The charge of Mr. Hill's general grounds of carelessness it would be difficult to surmise.

Let us now turn to the internal proofs of carelessness which Mr. LEONARD HILL draws from the experiments themselves. His first proof is (a), "an absolutely inefficient method was used to record the energy of the heart." Even if this were true, which it is not, this statement is no proof at all of carelessness in the performance of the experiments. It is simply a question of apparatus, and I will consider it in its proper place, namely, under his third accusation, of ignorance of exact physiological methods. His second proof is (b) "that chloroform was injected into the jugular vein after ligation of the vein, and was not washed on into the heart by normal saline solution." This experiment was cited by Mr. LEONARD HILL in his lecture as a proof of my ignorance of exact physiological methods.

In my reply I showed that his position was untenable, so he now shifts his ground and brings it forward as a proof of carelessness. He tries to do this by stating that it was not the method but the manner in which the injection was carried out that is open to severe criticism.

But in the two objections just quoted there is no question whatever of either carelessness or any other defect in the manner of performing the experiments, and it is only to the methods that Mr. HILL's remarks apply. These methods are (1) ligation of the vein previous to injection; and (2) omission to wash the chloroform into the heart by normal saline solution. I have already shown in my reply that in objecting to our method of ligaturing the vein before injection, Mr. HILL is in a minority, and that instead of my being ignorant of exact physiological methods, it is Mr. HILL who was either ignorant of the fact that the method I employed was the one recommended by BURDON SANDERSON, CYON, and GISEHENDEN, or else in his superior wisdom he sat in judgment on the writers of the best hand-books on physiological methods, and included them in the same condemnation with me. It is, therefore, unnecessary for me to discuss this objection any further. His objection to the second method, namely, that we injected chloroform into the jugular vein, and did not wash it into the heart with saline solution, I will answer by two questions: (1) If the chloroform reached the heart without the injection of saline solution, of what use would such an injection have been? (2) If the chloroform did not reach the heart, how did it kill the animal as it did?

The other experiments which I dealt with in my reply under the accusation of incompetence, but which Mr. HILL now brings in under carelessness, are those on the effect of alteration of position. I have already said that Mr. LEONARD HILL's statement with regard to them is absolutely incorrect, and I will again consider it under the charge of incompetence.

As I have already pointed out more than once, Mr. LEONARD HILL's accusation that many of the experiments performed by the Hyderabad Commission were so careless in execution that they could not for a moment be accepted by trained physiologists, applies in its present form to all their experiments, and must so apply until the experiments to which it actually does apply are specified so as to exclude those to which it does not apply. I asked

him to specify the experiments, and with the exception of those which I shall deal with under the head of incompetence his "many" have dwindled into one solitary experiment which he utilizes for a double purpose, employing it in his lecture as the basis of an accusation against me of ignorance of exact physiological methods and using it in his rejoinder as the basis of an accusation of carelessness; but as I have already shown, this solitary experiment upon which Mr. HILL would found so much, affords no basis whatever for either of his accusations.

Having thus examined the evidence by which Mr. HILL attempts to support his accusation of carelessness—an accusation which, if proved, would totally destroy the whole experimental work of the Hyderabad Commission—we find that it consists, first, in a fancy of Mr. HILL's that work is untrustworthy if it is done (1) in an out-of-the-way place, (2) with limited apparatus, and (3) in a short time, a fancy which fortunately for the world at large exists only in Mr. HILL's imagination, and does not correspond with facts; secondly, in a statement that the apparatus employed did not meet with Mr. HILL's approval; finally, we find that the "many" experiments which he denounced as untrustworthy have shrunk down into a solitary one, and even against this Mr. HILL's evidence of carelessness utterly breaks down. Such are the grounds on which Mr. HILL seeks to destroy the whole experimental work of the Hyderabad Commission.

I will now take up Mr. HILL's third accusation of ignorance of physiological methods. In his lecture he attempted to prove this charge by bringing forward the experiment of injecting chloroform into the jugular vein. In my reply I showed that this so-called proof was worthless, and that all the best text-books on physiological methods recommended the method I used. In his rejoinder he finds it convenient to shift his ground, and say it was not the method but the manner of using it that was objectionable, and he now brings it forward as a proof not of ignorance but of carelessness, and under this heading I have already dealt with it. Another proof which he brings forward in his rejoinder in support of his accusation of carelessness, but which, as I have already shown, ought really to have come under the heading of ignorance of exact physiological methods is that "an absolutely inefficient method was used to record the energy of the heart. A heart, when poisoned with chloroform, is thrown into paralytic dilatation; it continues to beat, but is incapable of emptying its cavities. A needle thrust into the heart would exhibit the efforts of contraction, it tells us nothing of the efficiency of action of that organ, and yet this was the method employed by the Commission." This statement of Mr. HILL's is a most extraordinary one, for if he has read the report, he must know that the Commission did not employ a needle in the heart in order to record its energy, but simply in order to ascertain whether it was contracting or not, for which purpose, as Mr. HILL himself acknowledges, it was amply sufficient.

I now come to Mr. HILL's last accusation—namely, that of incompetence. In this lecture he affirms that I, in experiments on the effect of altered position, paid no attention to the absolute necessity of placing the arterial cannula in the axis round which the animal was turned, and that by neglect of this simple precaution the experiments on the point were rendered utterly worthless.

Although it is in another place that he supposes the words "incompetent," yet if his accusation that I neglected the simple precautions were true, I should well deserve the epithet. But this statement is a pure product of Mr. Hill's imagination. It does not correspond to the facts of the case, and is therefore untrue. Nevertheless Mr. Hill considers that he was justified in uttering it, without taking the trouble to ascertain previously whether it were true or not, because he did not find in the report a statement that certain precautions were taken. The reason why no such statement appears in the report is that my long experience in physiological work has led me to look upon these precautions as so indispensable that I no more thought of mentioning them than I did of commencing my account of each day's work with the statement that the sun had risen, and consequently there was light enough to see our apparatus. For want of such a statement Mr. Hill may feel justified in rejecting all our experiments; and indeed, in order to be consistent, he ought to do so, for we have neither stated that the sun was up, nor that we employed artificial light when making our experiments, and consequently Mr. Hill has no assurance that we were not working in total darkness. But no amount of incredulity on Mr. Hill's part, nor of tenacity in holding to his fancies, will ever convert these fancies into facts, or change his statement from untruth into truth. It is curious to learn from the data with which Mr. Hill furnishes us how he came to make this unfounded statement. He is apparently unable to conceive of an axis without an axle, and so he postulates a swing board as a necessity for the experiment. His imagination, limited by the experience of the scanty supplies in a London laboratory, cannot picture to itself a supply of animals nearly of the same size, nor can he conceive that a floor may be temporarily heightened in the part required by means of blocks. Having thus laid down a canon to which experiments must necessarily conform, he condemns those which do not do so as being utterly valueless, in the same way as he condemned those which did not conform to his canon of carelessness. In neither case does it seem to have entered into Mr. Hill's mind that he could possibly be mistaken, and so he takes upon himself to act as the mouthpiece of trained physiologists, and, in this assumed capacity, to condemn our experiments without further inquiry.

I have now taken up Mr. Hill's accusations of prejudice, ignorance, carelessness, and incompetence, one by one, and have shown that all these accusations are absolutely groundless, and that the experiments of the second Hyderabad Commission are perfectly trustworthy, and may be accepted as such both by trained physiologists and by everybody else.

Dr. SHANMUGA.

NOTES ON THE HISTORY OF THE MIDWIFERY FORCEPS.*

By THOMAS MORE MADDEN, M.D., F.R.C.S., M.A.O.
Honorary Clinician, Royal University, Ireland; Obstetric Physician, Mater Misericordiarum Hospital; Consultant and Ex-Master, National Lying-in Hospital; Consulting Physician to the Children's Hospital, Dublin, &c.

THE history of the invention of the midwifery forceps, the abnormal frequency of its employment at one period, its consequent almost complete disuse at a later epoch, and its subsequent reintroduction into modern practice, form one of the most interesting chapters in the annals of our art. That chapter, moreover, is one that may not be undeserving of some reconsideration, inasmuch as it seems to me to convey a lesson, the practical application of which has been somewhat unfortunately lost sight of, owing to the too general neglect of ancient medical literature by modern practitioners. "The mental disease of the present day," says JOHNSON (and the observation is unquestionably more applicable now than when it was first made), "is impatience of study, contempt of the great masters of ancient wisdom, and a disposition to rely wholly on unassisted genius and natural sagacity. If no use is to be made of the labors of past ages, the world must remain always in the infancy of knowledge. The discoveries of every man must terminate in his own advantage; and the studies of every age be employed on questions which the past generation had discussed and determined."

I have elsewhere enlarged on this subject, and have shown that some of our most valued improvements in gynaecology and surgery—such, for instance, as the rapid dilatation of the os uteri, the local treatment of endometrial disease, the use of the vaginal speculum, the methods of hypnosis, and the employment of anaesthetics in surgical operations—are all instances of the modern revival of ancient practices. The same application applies to the history of the midwifery forceps, and I may here avail myself of some observations of mine in the Proceedings of a Society, now many years defunct in illustration of the fact that the very discussion which occasionally crops up as to the use of this instrument, as well as some of the modifications in its form, and in the methods of its employment which recent authorities have suggested were anticipated by our forgotten predecessors in the obstetric art.

Most of the writers who have treated of the history of the forceps since 1784, when MÜLLER'S "*Historia Literaria et Critica Forcepsium et Vectum*" was published, appear to have borrowed, not only their narrative, but also their quotations, at second-hand from this work, of which, therefore, I have not availed myself, but have compiled the following sketch of the history of this instrument, and taken my citations, as far as possible, from the original authorities.

The invention of the forceps is generally ascribed to the elder CRANMER, whose family monopolised the obstetric practice of London for three-quarters of a century.

* Reproduced from The English by permission.

When Dr. CHAMBERLEN acquiesces in the common opinion, "There can now be no doubt," he says, "of the credit of the invention being due to Dr. PAUL CHAMBERLEN, and I think it has been shown that there is presumptive proof that it took place before the year 1556."⁴

Having, however, devoted a good deal of attention to this question, it appears to me that the only merit the Chamberlains are entitled to is that of improving an old and less perfect instrument, designed for the same purpose, and described in works with which Dr. PAUL CHAMBERLEN, who lived at a time when medical literature was circumscribed in a language common to the learned in all countries, could hardly have failed to be conversant.

The forceps is not mentioned by any of the known Greek or Roman medical writers, whose obstetric knowledge, however, with the exception of CELSUS, was extremely limited. Midwifery was then almost exclusively confined to female practitioners, the higher class of whom, the *Medicæ*, were entirely distinct from the *Obstetrices*, as the mere midwives were called, and appear to have corresponded very closely to the "lady doctors" of the present day, and we have evidence that the forceps, or something of the same kind, intended for the same purpose, was not unknown to the latter at least eighteen hundred years ago, in the discovery of a similar instrument in the house of a Roman obstetrix in the excavations at Pompeii.[†]

The first-known reference to the forceps is that of AVICENNA, the Arabian physician of the tenth century, whose works were translated into Latin, and published at Basle in 1556, by ANDREW ALPAGO, from whose edition I have taken the following passage in which the author refers distinctly to the use of the forceps for the delivery of living children in cases of difficult labor, and makes this more evident by going on to direct that, in case the midwife fails with the forceps, she must then resort to embryotomy, as in the case of a dead child:—"Cap. 26. De Regimine ejus cujus partus sit difficilis causâ magnitudinis foetus—Oportet obstetrix bona faciat retentio hujus modi foetus. quare subtiliter in extractions ejus paulatim; tunc si valeat illud in se, bene est; et si non liget eum cum margine panni, et trahat cum subtiliter attractione post attractionem. Quod si illud non conferet, administrantur forcipes, et extrahatur cumilis. Si viro non confort illud, extrahatur cum incisione, secundum quod facili sit, ut regatur regi miles foetus mortui."[‡]

A century after that time we find two midwifery instruments, which, in the Latin version, are mentioned as "Forcipes," were described by ALBUCAZIS—i. e., the long forceps, or *Amiasch*, and the short forceps, or *Miasch*; but these instruments, from their construction, were obviously not intended for the extraction of a living child, and hence may be dismissed without further consideration.

The directions of AVICENNA as to the use of the forceps were repeated by MENCUCALUS, a writer of the sixteenth century, whose treatise, "*De Morbis Mulieribus*" was reprinted by SPACIUS in 1597. In this work he says:

⁴ *Observations on Operative Midwifery*, by Richard Churchill, M.D., p. 111, Dublin, 1744.

[†] Adams' Translation of Pausanias, Vol. I., p. 682.

[‡] *Arrested Midwifery*, Arabic Original, Liber Secundus de Medicis, Cordibus et Capitis per alios quatuordecim Capitulos et Arabico Textu in Latinum Conversum et notis, vixit ab Andrea Alpago Infante perennationis, etc., p. 736, Basile, 1556.

"When the labor is rendered difficult by the size of the child, AVICENNA gives the following rules:—Prima est ut obstetrix ament manibus educere. Si vero manibus non poterit, facia circumligatur festus corpus, atque ita paulatim educatur. Si vero hoc non succedat, habent obstetrices quosdam tentacula quibus circumligant pannos ac ligant vel offendant festum illicque educant."⁴

JACOBUS RUEFF, in his treatise, "*De Conceptu et Generatione Hominis*," published at Zurich in 1594, and reprinted in SPACIUS' collection—"Gynaecologium Greco-rum, Arabum, Latinorum, Veterum et Recentiorum, etc., Opera et Studio Israelis. Spacii Med. D. Fol. Argentinæ, 1597"—describes and gives an engraving of a midwifery forceps—"In hoc caso si popularerit necessitas, hinc instrumento forcipem qua dentem arcuatur adhibeas, vel depictam hinc forcipem longam et talem, qua ita utatur commodè, ut si possibile sit, id quod protrahendum est educat facilius."[†]

The earliest English reference to the use of any instrument, apparently for the same purpose, is contained in JAMES COOK'S *Mysticum Chirurga or Marrow of Chirurgery*, the first edition of which was published in 1647, and is quoted in Dr. AVELING'S interesting "Biographical Sketches of British Obstetricians," in the *Obstetrical Journal* for October 1873.

"Being commanded by the Lady Dowager BROOK to wait on her to London, to take the consult of physicians, in the way before we came to Tomsiter, we met with the tidings of that fatal fire of London, which caused her honor to resolve for Hackney. After some time of her being there I was desired by Mrs. MATTON to go visit one, near her time of her first child, who was aged. She begged of me to come to her if there was need. I told her there were several men abler than myself and fitted with instruments which I wanted, which might be had from the city (doubtless, here, says Dr. AVELING, he refers to PAUL CHAMBERLEN). After two or three days, in the night she sent for me. I being very much indisposed, and the night tempestuous, I denied; but, being very much importuned by a gentleman, I went. When come, I made trial and found the child come right, but without advantage, though pains were strong. I made use of what came next my thought, getting it a little better fitted at a smith's shop hard by, with which I brought away the child, though with much difficulty."

The forceps of AVICENNA, like those of JACOBUS RUEFF, were small and imperfect instruments, the blades being united by a fixed point, and therefore necessarily introduced into the vagina together and there opened to catch hold of the head of the child, as possible as! This same malconstruction occurs in CHAMBERLEN'S first forceps, which was merely an enlarged copy, with fenestrated blades, of the "forcipes longa et terna," described by RUEFF in 1524.

In CHAMBERLEN'S second forceps we find that he had discovered the inconvenience of the fixed point, and I think the only credit he deserves is that of opening and enlarging the blades, and doing away with this articulation. On their own showing, none of the CHAMBERLEN'S, from Dr. PAUL, the supposed inventor, down to Dr. HUGH,

⁴ *Microcholis in Specibus Gynaecologiae*, lib. p. 257, 1597.

the imitator of MAURICEAU's work, are entitled to much gratitude from posterity for their boasted discovery of an instrument professedly designed to save life and relieve suffering, but which they sordidly kept a close secret for their own aggrandisement. Up to the time when the sixth and last edition of his translation of MAURICEAU's first volume was published, in 1715, Dr. HUGH CHAMBERLEN retained his secret.

"My father, brother, and myself (though none else in Europe as I know), have, by God's blessing and our own industry, attained to and long practised a way to deliver women in this case without any prejudice to them or their infant, though all others (being obliged, for want of such an expedient, to use the common way) do, and must, endanger, if not destroy, one or both with hooks."

Some years ago, the late Dr. M'KEEVER, who was long distinguished as an obstetric practitioner, presented me, amongst other papers, with a manuscript containing a version of the history of CHAMBERLEN's failure with the forceps in his Paris case, as related in the earliest lectures delivered in Edinburgh, on midwifery. The first professor of this subject in that University was Dr. GIBSON, who was appointed in 1788, but died before entering on his professional duties, being succeeded by Dr. YOUNG, of whose unpublished lectures Dr. M'KEEVER's manuscript notes were recently before me.

Dr. YOUNG's account is evidently founded on MAURICEAU's from which it only differs in saying that—"The woman died under his hands undelivered, upon which he quitted Paris without selling his secret. This afterwards turned out to be the forceps, which had saved the lives of thousands that otherwise must have been lost. The next writer is GIFFARD, who practised about the same time with CHAPMAN, and it was he that introduced the frequent use of the forceps, and who perhaps had more practice with them than any of his predecessors, or even successors. . . . CHAPMAN only delivered six, and these with one single blade of the forceps. This single blade, or vectis, is what is called ROONHEESEN's secret, and in Holland none are allowed to practice midwifery without being instructed how to use this single blade by the professor appointed for that purpose."

The foregoing account of the introduction of the forceps into practice differs somewhat from that given in another manuscript, also recently in my possession, containing the unpublished lectures on midwifery delivered in Edinburgh in 1776 by Professor HAMILTON. In the latter it is erroneously stated that before attempting to use the forceps in his celebrated Paris case, CHAMBERLEN had obtained a thousand pounds from the French Government for divulging his secret. "This sum," says Dr. HAMILTON, "was readily granted, and he was called to the next laborious case that occurred, but in this he was foiled, and MAURICEAU afterwards delivered the woman by opening the child's head, but the woman died, as MAURICEAU mentions, from the instrument of the English operator wounding the uterus in several places. CHAMBERLEN left Paris and came home by Holland, and, it is said, there showed the forceps to ROONHEESEN; this, however, is disputed, but most certainly it was not known at Paris for a long time after—not, I believe, till

1784. Most certainly it was not known at the time that PARREY came to Paris to publish his system of surgery. . . . After CHAMBERLEN, CHAPMAN improved them, but very little. Both his and CHAMBERLEN's were straight, by which they could not be worked with without the handles injuring the woman very much behind. LEVERT introduced a curved pair. PARREY armed his with a crochet at one end and a blunt hook at the other, by which the practitioner went about armed at all points. PARREY's instrument is too long; however it is used all over the Continent with a very slight alteration.

SMELLIE, who had a very considerable mechanical turn, improved the forceps most. He first constructed a wooden pair, but he found this so difficult of application that he soon gave it up and had a steel pair made. Dr. WALLACE JOHNSTON next improved the forceps; he added the curve of LEVERT; increased the breadth of the blades and diminished the weight of the instrument. The London practitioners are every day inventing new ones, but they are in no degree superior to this. After all that has been said about the forceps, I may now remark that a man who has been used to deliver with instruments may deliver with the shafts of a couple of spoons; yet young practitioners find considerable difficulty in delivering with the modern forceps."†

The case in which CHAMBERLEN failed to effect delivery with his forceps in Paris, as narrated by MAURICEAU, reflects more credit on the English than on the French accoucheur—the latter left the woman to die undelivered, the former at least attempted to assist her:—"On the 19th of August 1670," says MAURICEAU, "I saw a small woman, aged thirty-eight, who had been in labor of her first child for eight days. The waters escaped on the first day without hardly any dilatation of the os. Remaining in this condition until the fourth day, I was sent for, and recommended the midwife to bleed her; and in case this did not produce the effect I hoped, to administer an infusion of senna to excite pains, which she had not; this was done the following day, and succeeded in causing pains, by which the mouth of the womb was dilated as far as possible. Nevertheless, I could not deliver, and the child had remained in the same situation, without been able to advance, for this woman was so small, and the bones (of the pelvis) so narrow and close to each other, and the sacrum so curved forwards, that it was quite impossible to introduce the hand to deliver her, although mine is small enough . . . or to introduce the fingers sufficient to enable me to use a crochet safely, so as to extract the child, which had been apparently dead for about four days. I declared the impossibility of delivering this woman to my assistants, who, being well persuaded of this, prayed me to perform the Cæsarean operation, which I would not undertake, knowing well that it was always certainly fatal to the mother. But after I had left the woman in this condition, it not being possible for me to help her as I would any other of a more normal conformation of body, there came shortly afterwards an English physician named CHAMBERLEN, who was then in Paris, and who, from father to son, made a profession of midwifery in England, in the town of London, where he thus acquired the highest reputation in that art.

* Dr. Young's Manuscript Lectures.

† Dr. Hamilton's Manuscript Lectures, Vol. I, p. 328.

This physician finding the woman in the condition just stated, and knowing that I had not found any possibility of delivering her, declared himself astonished that I could not do so." *Mor* (says MAURICEAU, with all a Frenchman's untranslatable vanity), qu'il devoit assurément être le plus habile homme de ma profession qui fort à Paris; notwithstanding which he at once promised to deliver her most assuredly in less than half a quarter of an hour, whatever difficulty he might find. Accordingly, he immediately applied himself to the business, and in place of half a quarter of an hour he worked for more than three entire hours without cessation, except to take breath. But having vainly exerted all his strength as well as all his industry, and seeing that the poor woman was almost dead in his hands, he was obliged to abandon the attempt and to allow that he could not accomplish it, as I had well-declared. This poor woman died undelivered twenty-four hours after the violence he had done her, and at the examination I made in performing after her death the cesarean operation, which I would not do before, as I had said, I found the child and everything else as I had before stated, and the womb all torn and pierced through in several places by the instruments which this physician had blindly used without the control of his hand, which being a size larger than mine, he did not seem to have been able to introduce sufficiently far so as to preserve it." MAURICEAU then goes on with great complacency to observe that the English physician, who had come six months previously to Paris, in the hope of making his fortune, had circulated a report that he had a secret (*tout particulier*) for such cases, and vaunted that he could thus deliver in even the most desperate and otherwise hopeless cases in less than half a quarter of an hour, and had even proposed to the first physician to the King that for a reward of ten thousand crowns he would disclose his pretended secret. "Mais la seule expérience de ce fâcheux accouchement le dégoûta tellement de ce pais-là, qu'il s'en retourna peu de jours en suite en angleterre; voyant bien qu'il y a Paris de plus habile gens en l'art des accouchemens que lui." Before leaving Paris CHAMBERLEN called on MAURICEAU, and after various compliments had passed between them, the latter thus concludes his account of the visit:—"Je reçois son compliment comme je devois lui faisant entendre qu'il s'était bien trompé en croyant trouver autant de facilité à accoucher les femmes à Paris, comme il avoit pu trouver à Londres ou il retourna le lendemain emportant avec lui un exemplaire de mon livre; qu'il fit imprimer après l'avoir traduit en Anglois en l'année, 1672, depuis laquelle traduction il s'est acquis un si haut degré de réputation dans l'art des accouchemens dans la ville de Londres, qu'il y a gagné plus de trente mille livres de rente, qu'il possède présentement."^o

Amongst the writers who took part in the introduction into midwifery practice of instruments intended for the same purpose as the forceps, a prominent place must be assigned to M. JEAN PALFYN, of Ghent.

In 1708 PALFYN published at Leyden an anatomical

continuation of MAURICEAU's work;^o and twelve years later, being at Paris bringing out a new edition of his book, he presented to the French Academy of Science what he termed his *tire-tête*—a kind of extracting forceps, the handles of which did not cross, but were simply connected together by a ligature.

Although CHAMBERLEN and, in a lesser degree, CHAPMAN have generally been given the credit of introducing the forceps into English midwifery practice, the first who avowedly employed and recommended the use of this instrument was Mr. WILLIAM GIFFARD, surgeon and man-midwife, who died before CHAPMAN's book appeared. GIFFARD appears to have used his "extractor," as he calls it, almost as freely as any modern accoucheur does the forceps, and moreover, anticipated SMELLIE's plan of dilating the os uteri to apply this instrument, which has been again revived.

The first case in which GIFFARD employed his "extractor," or forceps, occurred on the 8th of April 1726, the patient being the wife of one of the Prince of Wales' servants, and, owing probably to the inexperience and timidity of the operator, was unsuccessful.

Two years subsequently he relates the first published case in which the forceps was successfully used for the delivery of a living child. This occurred on the 28th of June 1728. The woman had been for many hours in "labor which was delayed by inertia; and having first administered a clyster and two cordial hypnotic draughts," at intervals of eight hours, he says:—"I then found the child but little advanced, her pulse was very quick and laboring, and the womb very much spread, so that I could entirely pass my fingers round the head to the ears, for it was no ways engaged, but loose wherefore considering that her pulse grew languid, and that her strength decreased, I thought it advisable to attempt her delivery. I endeavoured to press the child back, that I might be able to turn and get the feet, but it was so locked at the shoulders that I was not able to move it, whereupon I passed my extractor and drew it with much difficulty forwards without the labia. . . . The child was born alive. This case proves that a child presenting right, but sticking in the passage, may be brought alive (I won't say always) without either the use of hooks, or lessening the head, contrary to the opinion of most former writers."[†]

GIFFARD occasionally narrates the history of more than one forceps case occurring in the same day as an ordinary matter. Thus, on the 17th of May 1731, he met with two cases "where," he says, "I thought it advisable to lend my assisting hand." The first was a case where the head was for some hours impacted in the pelvis; and the second is a case—interesting at the present time, when the same practice is again recommended—of labor delayed by rigidity of the os, where he "was of opinion that the delivery ought to be immediately effected in respect both of the mother and of the child. . . . But as the os internum was not so fully dilated as readily to admit the passage of the head through it, I strove to stretch and widen it by putting the ends of my fingers between it

and the child's head, and by this method, made way for the steady passing of the instrument, without bruising or tearing the parts."

To EDWARD CHAPMAN is due the credit of first making CHAMBERLEN'S secret known to the profession, as well as of improving its construction by substituting hard for soft metal, and diaining the rivetted lock long retained in some French and American forceps. In his "Treatise on the Improvement of Midwifery," published in 1783, CHAPMAN states that difficult labors, where the head lies low, can only be accomplished by either the fillet or by the forceps. "As to the forceps," he says, "which, I think, no person has yet any more than barely mentioned, it is a noble instrument, to which many now living owe their lives, as I can assert from my own knowledge and long successful practice."

The frequent use into which the forceps came as soon as it was known is evinced by numberless contemporaneous authorities; but by none more clearly than by the author of a letter addressed to CHAPMAN, and published in the third edition of this book. "All I can say," reiterates CHAPMAN, "in praise of this noble instrument must necessarily fall short of what it justly demands."

The following letter was sent to me by a gentleman who has been recommended to me for information in this art, and has long practised with great success and applause.—

'Sir, if you please to remember, about a week after I came into the county, I acquainted you that I was called to a woman in labor, where the child presented with the head far advanced in the vagina, with the os uteri extending. I delivered her with the forceps, and neither the mother nor the child received the least injury. Since that time I am come into such credit that I am frequently called in twice or thrice a week; and, I thank God, I have not, as yet, met with the least mishap. Our midwives here are pretty dexterous, but when the head falls so low as to require the use of the forceps, they are at a loss. I have had two cases where I was obliged to deliver feet-ways, the heads of the infants not offering directly right for the instrument. All the rest I delivered with the forceps.—Yours &c., JOHN PARRY, Sullworth, 30th October 1784.'†

The years 1783 and 1784 are memorable in the history of the forceps, for not only were GIFFARD'S and CHAPMAN'S works then published, but, at the same time Mr. ALEXANDER BUTTS, Surgeon in Edinburgh, communicated to a Society in that city. "The description of a forceps for extracting children by the head when lodged low in the pelvis of the mother."

"The forceps," he says, "for taking hold of a child's head when it has fallen so far down among the bones of the pelvis that it cannot be pushed back again into the uterus, to be extracted by the feet, and when it seems to make no advances to the birth by the throes of the mother, is scarce known in this country; though CHAPMAN tells us it was long made use of by Dr. CHAMBERLEN, who kept the form of it a secret, as Mr. CHAPMAN also does. I believe, therefore, that a sight of such an instrument—which I had from Dr. DUSA, who practices midwifery at

Paris, and who believes it to be the same as that which should not be unacceptable to you, and which, I think, the picture of it may be of use to some of your correspondents."

In 1742 the use of the long forceps, which is now to have been even then "in general use all over Europe," was described by Mr. (afterwards Sir) FLEMING OULD, who succeeded Dr. MOSSÉ as the second Master of the Dublin Lying-in Hospital. OULD'S work is very interesting, as it contains clear directions for the performance of caesarean as a substitute for craniotomy in certain cases of obstructed labor, for the proposal of which the late Sir JAMES SIMPSON obtained so much credit a hundred years afterward. OULD also forestalled a suggestion made a few years ago by the late Dr. BEATTY for preventing impending laceration of the perineum and retrovaginal septum during labor by incising the perineum. But on the subject of the forceps OULD merely repeats the directions of former writers. Speaking of labors delayed by disproportion or inertia, where the child is living, "or rather, if there be not a certainty of its death, in this case," he says, "the best adapted instrument is the long forceps, which is in general use all over Europe, wherefore it needs no particular description. . . . Being thus provided, we proceed to the operation by placing the woman on her knees, &c."†

Immediately after its publication, OULD'S work was unsparingly attacked by a rival Dublin accoucheur, Dr. SOUTHWELL,‡ who printed two pamphlets on the subject—one in Dublin, and the other shortly afterwards in London. In the former he reproaches OULD with being "the youngest surgeon practising midwifery in this city, a man not conversant with authors, and at best, but a novice in practice. . . . I shall only add, in general, Mr. OULD is totally ignorant of the regular use of instruments. He entirely mistakes the right use of the large forceps."§

(To be continued).

THE RENAL ORIGIN OF GOUT AND SOME POINTS IN THE TREATMENT OF THE DISEASE.*

By ARTHUR P. LUFF, M.D., B.Sc., F.R.C.P.

Physician in charge of Out-patients in St. Mary's Hospital, London

THREE views chiefly obtain as to the primary causation of gout:—(1) Excess of uric acid, (2) morbid changes in the structure of tissues, whether of an inflammatory, degenerative or necrotic nature, and (3) nervous disturbances. Now uric acid neither can nor does exist in a free state in the blood where it is usually found as the soluble sodium quadricarbonate $\text{NaH}(\text{C}_2\text{H}_3\text{N}_2\text{O}_6)_4$, $\text{H}_2(\text{C}_2\text{H}_3\text{N}_2\text{O}_6)_4$ which is very unstable and after a time combines with the sodium-carbonate of the blood to form the very

stable and comparatively insoluble sodium biurate, $\text{NaH}_2\text{B}_6\text{O}_{12}$, which, if produced in larger quantities than the fluids of the body can contain in solution, becomes deposited in the crystalline form in the various structures by mechanical irritation provokes an inflammatory attack which constitutes the gouty paroxysm.

Whence does this uric acid come? Is it a normal constituent of the blood or does it only appear under abnormal pathological conditions? It is undoubtedly a normal constituent of the urine, from 8 to 10 grains of uric acid being daily excreted by a healthy adult. If this uric acid is not brought by the blood to the kidneys, it must be secreted and excreted by the latter, and if the kidneys failed to excrete all the uric acid they manufactured, it follows that the residual amount must either be retained in the kidneys or be absorbed from them into the general circulation.

If uric acid be absorbed from the kidneys in gout, there ought, in at least the early stages of the disease, to be a deficient elimination of that body in the urine. And so there is. PFEIFFER (*Berliner Klinische Wochenschrift*, 1892, p. 416) found that the quantity of uric acid excreted by gouty subjects was always lower than that excreted by healthy persons of the same age. In the following table are the results, calculated in grammes per 100 kilogrammes of body weight, of the daily determinations made by the author for eight successive days of the total uric acid excretion in the urine of three males, between 40 and 50 years of age, of whom A was perfectly healthy, B was suffering from subacute gout supervening on chronic gout, and C had chronic gout complicated with lead poisoning and recent pain in the right metatarso-phalangeal joint and in both ankles —

Day.	A	B	C
1	1.105	0.260	0.576
2	1.027	0.268	0.617
3	1.020	0.316	0.665
4	1.376	0.350	0.715
5	1.175	0.442	0.448
6	1.030	0.558	0.372
7	1.252	0.56	0.598
8	1.208	0.494	0.594
Average	1.148	0.398	0.572

Again, if instead of being formed in them the uric acid is conveyed to the kidneys by the blood, we ought to be able to detect it in the blood; but, as a matter of fact, the blood of man and other mammals in health is always free from uric acid, though urea is always present. In all cases where granular kidney disease is accompanied by deficient elimination of uric acid in the urine, there is always an appearance of uric acid in the blood.

While VON JAKSCH (*Deutsche Medicinische Wochenschrift*, 1890, XXXIII, p. 741), KLEMPERER (*Ibid*, 1895, XXI, p. 655), and the author (*Lancet*, 1897, Vol. I, p. 868) completely failed to find so much as a tiny trace of uric acid in the blood of several healthy persons, Sir A. GARROD met with a like result in the blood of the ox, sheep and pig; but urea was found in every sample of blood examined.

Sir W. ROBERTS has shown that the semi-solid white mortar-like urinary excrement of birds consists, (apart from the small quantity of water present) entirely of uric acid compounds, such as the quadrates of ammonium, sodium and potassium, and that in proportion to their body-weight, the output of uric acid by birds is

enormous when compared with that excreted by mammals; but not a particle of urea is voided. Then it follows that if this large quantity of uric acid be produced in the organs and tissues generally, it must be conveyed in the blood to the kidneys and should be easy of detection in their blood; but the most careful examination by numbers of observers among whom were the author and Sir A. GARROD, has shown beyond doubt that though the blood of birds always contains urea, it is absolutely free from uric acid.

If the view be correct that the kidneys play merely the part of a filter in the elimination of the uric acid from the blood, how is it that the mass of experimental evidence shows that uric acid is never present in the blood of healthy human beings, nor has it ever been found in the blood of birds whose urinary excretion is almost entirely composed of uric acid compounds?

Further proofs of the renal origin of uric acid are furnished by the facts that in all cases of renal disease, and more especially in granular kidney disease and uræmia, uric acid is always present in the blood and deficient in the urine, while uratic incrustation of articular cartilages is not uncommonly found, as shown by the subjoined table at the *post-mortem* examination of subjects of kidney disease who have never been known to suffer from ostensible gout during life —

	Number of cases.	Uratric deposit in joints.
Known to have had gout	10	10
Never known to have had gout but whose kidneys were	41	11
(Slightly granular)		
(Markedly granular)	26	30
Total	77	41

The kidney lesion that causes gout is not easy to determine; but the author believes that a functional affection of the kidneys always precedes gouty manifestations, and that this functional lesion, which may be started by various agents and causes (among which are excessive indulgence in nitrogenous foods, wines and beer, the toxic effect of lead, and the influence of nervous impulses such as mental shocks, severe accidents, &c.), may subside on the removal of the exciting cause, or it may pass on to a structural lesion which is then of the contracted granular type and may also be transmitted by heredity.

The anatomical seat of the kidney affection is probably in the epithelium of the convoluted tubes, as that is the primary seat of disease in granular kidney and the increase of interstitial tissue is probably a secondary change, while granular kidney is not always evidenced by the occurrence either of albuminuria or of dropsy, and during life there may be no external manifestations of the existence of such renal mischief as the *post-mortem* may disclose.

On the whole, there is abundant evidence showing the direct connection between kidney trouble and gout, since uric acid has always been found in the blood in cases of renal disease, while uratic deposits are frequently found in the kidney and joints of gouty subjects and in the joints of persons with renal disease but who have never been known to have had ostensible gout and kidney mischief is frequently met with at the *post-mortem* of gouty subjects.

The *nuclein* derivation of uric acid in diseases such as leucocythemia, pernicious and ordinary anemia, pneumonia, &c., where considerable amount of uric acid may appear in the blood, is proved by the researches of HONBACZEWski, VON JAKSCH, SADOWiNJ and FORMANCK, who make it highly probable that in these diseases the uric acid is produced in the system from the nuclein of the disintegrating leucocytes; but no symptoms of gout are developed with or from these diseases, and as the kidneys remain in a sound condition, the uric acid is readily and rapidly excreted by them.

Then there are many facts to support the view that *urea* is at least one of the sources of formation of uric acid, and that the change is effected in the kidneys by the conjugation of urea and glycocine, which latter is a natural product of the human organism and is formed by the decomposition of the glycocholic acid of the bile. This is all the more probable since in the first place uric acid can be made experimentally by the interaction of urea and glycocine. $\left\{ \begin{array}{l} 3 \text{CH}_3\text{N}_2\text{O} + \text{C}_6\text{H}_5(\text{NH}_2)\text{O OH} \\ \text{urea} \qquad \qquad \text{glycocine} \end{array} \right\} + \left\{ \begin{array}{l} \text{C}_6\text{H}_5\text{N}_2\text{O}_2 + 3 \text{NH}_3 + 2 \text{H}_2\text{O} \\ \text{uric acid} + \text{ammonia} + \text{water} \end{array} \right\}$ and in the second place, in the carnivora whose urine contains little or no uric acid, the bile is devoid of glycocholic acid and therefore yields no glycocine.

Alterations in the metabolism of the liver necessarily affect the formation, excretion and daily elimination of uric acid by healthy individuals, and as variations in the metabolism of the liver are induced by changes in the quality and quantity of food ingested, by the amount of exercise and by various nervous influences, it can be readily understood why liver trouble of some kind or another frequently accompanies gouty dyspepsia, and the fact is explained how several observers, unable to dissociate the connection between liver troubles and gout, have attributed the formation of uric acid to the liver.

The uric acid formed in the kidneys is at once converted into the quadriurates of ammonium, potassium and sodium, and in healthy persons excreted dissolved in the urine from which they sometimes separate, on cooling, as a deposit of "amorphous urates." In gouty conditions these urates are absorbed into the blood, where the sodium carbonate converts the ammonium and potassium quadriurates into sodium quadriurate, which is an unstable salt and is gradually transformed into the less soluble and less easily excreted sodium biurate, which first passes into the hydrated or gelatinous modification, but if it be present in the blood in greater amount than that fluid can retain in solution, it passes with the lapse of time and increasing accumulation into the almost insoluble anhydrous or crystalline condition and is deposited in those tissues (of the connective tissue class) which either on account of having received previous slight injuries or because of their poor vascular supply favor its deposition.

The treatment of gout should aim at (1) checking excessive formation of uric acid in the kidneys, (2) preventing its absorption into the blood, and (3) promoting the removal of uratic deposits by facilitating the elimination of the quadriurate and biurate contained in the fluids of the body.

To check the excessive formation of uric acid, promote liver metabolism and relieve congestion of the portal system by regulating diet and regimen, colchicum and

gusiacum, as stimulants of hepatic metabolism, are very useful in many forms of gout. Constipation and the congestion of the portal system may be relieved by occasional doses of blue pill followed by an Epsom salts purge. Or sulphur, gusiacum tablets, or compound liquorice powder may be given if more frequent use of a laxative is needed.

To promote the elimination of the quadriurates formed in the kidneys and so prevent their absorption into the blood is to strike at the primary evil in the causation of gout. To do this (1) promote increased diuresis and (2) diminish the acidity of the urine. Free diuresis should be encouraged by drinking plenty of water. Citrate of potassium is a good diuretic which not only increases the solubility of the quadriurates, but also diminishes the acidity of the urine and should be pushed until moderate alkalinity of the urine is produced.

The removal of uratic deposits and the elimination of quadriurates and biurates from the system may be attained by (1) free diuresis, (2) baths and suitable exercise, and (3) the careful selection of a mixed diet with a fair amount of vegetable food, since the mineral constituents of certain vegetables, such as Brussels sprouts, cabbage, French beans, spinach, turnips and turnip tops, possess to a remarkable degree the double function of inhibiting the conversion of sodium quadriurate into the biurate and increasing the solubility of the latter; but the idiosyncrasy of each patient to various articles of diet must be made the subject of careful observation.

Based as it is on the assumptions that alkalies (1) neutralise the general acidity of the system and render soluble (2) the uric acid present in the blood and tissues, and (3) the biurate deposited in the joints, the plea for the treatment of gout by means of alkalies is certainly erroneous, since (1) KLEMPERER has conclusively proved that the alkalinity of the blood of gout is but very little, if at all, diminished, and that corresponding variations in the alkalinity of the blood may frequently be met with in healthy persons. (2) In gouty people uric acid is never present as such in the blood and tissues, where it is always found combined with sodium as the quadriurate or biurate, and (3) Sir WILLIAM ROBERTS has found that the phosphate or bicarbonate of sodium diminish instead of increase the solubility of sodium biurate, while potassium bicarbonate does not at all influence its solubility.

Dr. HAIG's sodium salicylate treatment is open to the objection, that though it does cause increased elimination of uric acid in the urine, it unites readily with glycocine to form salicyluric acid and thus brings an increased amount of glycocine to the kidneys where it combines with the urea necessarily from an increased amount of uric acid.

RENAL CALCULUS.*

By J. H. MUSSEY, M.D.,
Assistant Professor of Clinical Medicine of the University of Pennsylvania.

In referring to the clinical aspects of renal calculus, which ought rather be called "nephrolithiasis" or "better still, "stone in the kidney," I have to call attention to features which, coming within my experience, are essential in the diagnosis, though they are somewhat at variance with text-book teachings.

The symptoms ascribed to the presence of a calculus in the pelvis of the kidney are pain, intermittent hæmaturia,

* Read before the Buffalo Academy of Medicine and specially reported for the Indian Medical Record.

pyuria, pyelitis, renal intermittent fever, frequent micturition and renal colic; but here is a huge dendritic calculus, which filling the pelvis and calices, so as to form a complete mold of the cavity of his kidney was discovered in the dissecting room in the body of an aged negro who died in the Philadelphia Hospital in 1887, of debility, but neither had any determinable organic disease nor complained of pain, pyuria or any other symptoms of renal calculus during the many years this stone was slowly growing to its present size.

Looking up my notes of 40 cases (29 in private and 11 in hospital practice) I find that while the youngest patient I treated was 25 years of age, the oldest was 69, and the ages of the remaining 38 cases ranged from 35 to 55. 21 only of these 40 cases were females, though most authorities hold to the preponderance in women, the ratio being 3 females to 1 male.

Pain is of more diagnostic significance in renal calculus than in any other renal affection; but it must be studied closely to determine its value, since pain over the kidney behind and along the margin of the ribs anteriorly may also be due to renal hyperemia, nephritis, pyelitis, tumours, malignant disease, and myalgia of rheumatic or other causation than renal calculus, where pain comes and goes, and is more commonly intermittent and paroxysmal, though it may frequently be constant and localized in the kidney region or anteriorly along the margin of the ribs below the gall-bladder region and remote but related areas and nerve-courses may join in the pain chorus, whose very vagaries (like the flitting nerve-aches of hysteria with which it must not be confounded) render it one of the most valuable signs of renal calculus. Remember also that the pain be aggravated by the function of menstruation and even bear close relationship to it.

Hæmaturia is the classic, most constant and positive symptom of renal calculus, but other causes of hæmaturia exist and are well known. Thus during the past six years 2,923 samples of the urine of 1,997 persons were critically examined with the result that blood was found 364 times in the urine of 264 of these persons, and these 264 were suffering from:—

Acute Bright's Disease	19	Gout	...	1
Anæmia	...	Gout	...	8
Appendicitis	...	Jandice	...	1
Arterio-Capillary Fibrosis	...	Neurasthenia	...	5
Bright's Disease (chronic)	...	Pneumonia	...	5
Bronchitis	...	Pregnancy	...	17
Cardiac dilatation or Valvulitis	...	Rheumatism	...	28
Catarrhal Fever	...	Renal Calculus	...	28
Diphtheria	...	Tonsillitis	...	1
Erysipelas	...	Tuberculosis	...	2
Gastric disorders	...	Typhoid Fever	...	5
Gastro-intestinal catarrh	...	Unknown	...	20
	...	Venereal Disease	...	17

Therefore must we look to the accompaniments of the disease rather than to the disease itself to explain the hæmorrhage as it not infrequently happens that the trauma from the discharge of the urinary salts accompanying affections such as gout, rheumatism, &c., is sufficient to produce bleeding. Blood cylinders, though they denote hæmorrhage from the renal substance, are rarely, if at all, present in renal calculus. Bloody urine may arise from various sources and its presence is not of any particular significance during the violent throes of an attack of pain during the presence of fever or of any abdominal disorder disturbing the balance of the circulation, while in a middle aged person with uric or oxalic acid tendencies, by virtue of heredity, occupation and habits, in whom no cause for

the hæmorrhage can exist in the bladder, prostate or urethra, the chances are that it is of pelvic origin due to the irritation of gravel or of urine densely loaded with salts. If in the absence of heart disease, blood-dyscrasia or other extraneous condition cause it, the hæmaturia still persists when the patient is put at absolute rest, the hæmorrhage is more likely of a cancerous or tuberculous origin, and KLEMPERER (*Deuts. Med. Woch.*) who calls attention to hæmaturia of the healthy kidneys as the result of over-exertion on horseback or bicycling, found it also present in 4 cases of hæmophilia and a group due to an angioneurosis. The reaction of the urine must be borne in mind and all other possible factors for it carefully eliminated before coming to a conclusion that the hæmorrhage is of renal origin. Cystoscopy must be resorted to and ureteral catheterization.

Pyuria is looked upon by all authorities as almost essential to the diagnosis of renal calculus; but I disagree with them, and believe that pyuria is not present except as an accidental complication from infection either before the stone has obstructed the ureter, or from infection extending from below upwards.

Albumin, which is of frequent occurrence, neither implies a co-existing nephritis nor does its presence, whether alone or with the co-existence of casts, deter one from surgical interference in a case of uncomplicated renal calculus. Nor should larger amounts deter one if pyelitis be present.

Casts infallibly point to calculus if they are long, narrow, hyaline and persist without other kinds, in the presence or absence of albumen.

The specific gravity of the urine is a cogent aid to diagnosis, and its persistence above the normal enables one to exclude renal cirrhosis, hysteria or a renal neurosis.

Frequent micturition without tenesmus is not indicative of stone in the kidney.

Paroxysmal Renal Fever rarely occurs, but when present, may be due to (1) calculus, (2) absorption of retained products if the kidney is floating and becomes twisted or (3) pyelitis.

The diagnosis of renal calculus requires great patience and care, and is greatly assisted by careful investigation of the family history and the duration of the symptoms. As it is not impossible that healthy kidneys are too often operated on or the kidney of the wrong side cut down upon because the case was not carefully studied over a long period of time, I plead for delay and patient study of the every-day phenomena with the every-day means at our command, though the occurrence of an accident such as obstruction demands prompt action. However, if care be taken, a correct diagnosis may be established by the symptom-complex of pain, local tenderness, persistent hæmaturia, albuminuria, casts, renal colic and passage of fragments of stone.

I have had no experience with ureteral catheterization and exploration; but I agree with HOLLANDER that we can do without their diagnostic aid in the majority of cases and thus avoid the danger of infection from below. Of course if we had a CASPER, a KALLY or a MANN, whom we could conjure up at a moment's notice to do the catheterization for us, it will be well enough; but to trust such a highly risky and dangerous means to the general practitioner would be to court a repetition of the disasters from uterine specula and uterine sounds.

In the hands of well experienced manipulators the Roentgen rays will, in many cases, disclose the presence of stone, and while I am well satisfied with the use of rain water, diet, exercise and other hygienic lines of treatment followed, I am also in accord with the indications laid down in the works on surgery (such as pain that disables, obstruction and pyelitis demanding surgical intervention), but for all that I unhesitatingly am against all operative measures, unless a diagnosis is fully established, which can be done if we take time and view broadly.

A MIRROR OF PRACTICE.

A CASE OF STRICTURE OF THE PYLORUS IN WHICH GASTRO-ENTEROSTOMY WAS PERFORMED WITH THE USE OF A MURPHY BUTTON.

By W. J. WARDLAW, M.D.

Missionary Physician. In charge Miraj S. M. C.

HOOBAIN, J., Mahomedan aged 35, occupation hawaladar, family history negative. For two years suffered from flatulence, pyrosis, pain in the epigastrium of a dull aching character and radiating over the sternum and occasionally through to the back and always exaggerated by eating and relieved by vomiting. No history of hæmatemesis or intestinal hæmorrhage. During first year of his illness was treated in a State Dispensary for "liver" and dyspepsia, but without relief. Before entering this hospital he was treated in the out-door department for upward of a year. During this time, gastric stimulants, sedatives, restricted and regulated diet were all used in turn or in combination but with only temporary relief. Emaciation continued in spite of all treatment, and the patient was finally admitted as an in-patient on the 3rd January 1898.

Condition on admission.—Strength poor; able only to walk a few steps unaided; emaciation marked; weight 98 lbs.; pulse 60, good volume; anemia very slight; tongue slightly coated with light fur; appetite poor; fears to eat on account of distress caused by food; ingestion of food always followed in from two to four hours by flatulence, eructations and pain in the epigastrium; bowels slightly constipated; chest examination negative; liver and spleen not perceptibly enlarged; epigastrium distended. Distension of stomach by air and water shows lower border 10 below umbilicus. Gastric peristalsis visible through the abdominal wall. A test meal showed undigested particles of rice and native bread 30 hours after ingestion. Free hydrochloric acid present in the washings six hours after a meal. Urine scanty, 24 ounces in 24 hours; S.G. 1030. No albumen or sugar.

Diagnosis.—Benign stricture of pylorus with gastritis. The patient was put on a liquid diet for some days. Lavage of the stomach was practiced daily with hot water at a temperature of from 110 to 115, a gallon being used on each occasion. Strychnine in full doses was also administered together with small doses of belladonna. At the end of eleven days the patient's condition improved. His temperature ranged between 97 and 98°F. Operation was now advised and gladly accepted.

14th January.—The patient's bowels having been freely moved two nights previously with calomel and magnesia, and the abdomen prepared by scrubbing with brush and green soap, shaved, lathered with chloride of lime and washing soda, washed with boiled water, and a towel rung out of 1 in 500 bichloride bandaged on the abdomen and lower chest over night, the patient was ready for operation.

(Operation.)—I was assisted by Dr. A. E. WILSON and the native hospital staff. The legs and chest were wrapped in flannels and hot water bags applied to the

lower extremities. All instruments and towels (soiled dry) were sterilized by heat. The abdominal wall was removed, the abdomen and lower portion of the chest were wiped with alcohol and sterilized water. A 4-inch median incision extending from within 1 inch of the sternum cartilage was made and the abdominal cavity opened. The stomach (which immediately before operation had been thoroughly washed out with borie acid lotion) presented. Examination showed the viscera to be large and the lower border flabby and extending to midway between enciform cartilage and umbilicus. The pyloric extremity was found to be hard and thickened; the thickened portion extended about 2 inches into the duodenum. No nodules were present, and no enlarged mesenteric glands were discovered. The colic mesentery was considerably thickened and its vessels greatly distended, due, no doubt, to the pressure of the constantly loaded stomach. The stomach itself was not abnormally congested; the liver and spleen were not enlarged. A loop of small intestine was now sought for and followed up to the duodeno-jejunal angle, a little below which point a Murphy button, (the largest size) was now placed in the usual way for lateral anastomosis, and held in place with an ordinary artery clamp. The stomach was now brought up through the opening and into the abdominal wound, and a site free from large vessels chosen, the incision made, the other (female) half of the button was inserted and the anastomosis completed. A backing up whip stitch of fine silk was run around the button to ensure additional safety. During the anastomosis the peritoneal cavity was shut off by means of gauze packed around the bowel and stomach. The abdomen was closed in two layers; continuous catgut being used for the peritoneum and interrupted silk-worm gut for the remaining structures. Acetanilid was dusted over the line of suture, iodoform and bichloride gauze, sterilized cotton wool and a binder completed the dressing. The operation lasted 70 minutes, a considerable portion of which was consumed in preliminary examination of organs adjacent to the stomach and in determining the cause. Pulse was 85 at the close and there was no shock. The patient retched well. He was fed entirely by the rectum for the first 48 hours, and subsequently by the stomach and rectum for two weeks; the amount of nourishment by the mouth being gradually increased. After this time nourishment per rectum was discontinued.

Following the operation the temperature rose three times to 100.5 on the fourth to the seventh day. After that it continued subnormal for a week and finally rose to the normal point. The stitches were removed on the ninth day, the wound having healed by first intention. Two small stitches subsequently gave way, but in no way effected the line of union. They healed in a few days under appropriate treatment. On the sixteenth day at noon the patient was suddenly seized with an attack of acute pain referred to the umbilical region, which was followed by vomiting, projectile in character. Some 80 ounces of bile-stained liquid was vomited, followed by relief from the pain but resulting in marked exhaustion. The whole abdomen, which a few minutes previously was fairly distended, was now markedly scaphoid and placid. Palpation of its contents failed to reveal the site of the button. The patient was surrounded with hot water bags,

the patient vomited a quantity of dark green, bilious material during the 24 hours by regurgitation and belching to the stomach. He reacted promptly and after feeding per rectum for 24 hours, nourishment by the mouth was again resumed. Twelve days later the patient had another attack very similar to the one described above but less severe; the fluid vomited on this occasion (1 quart) being of a dark greenish color.

From this the patient gained steadily. He has been entirely relieved of his gastric distress; takes his meals with relish, and at the time of dismissal, on 4th April 1898, had gained some 20 lbs. in weight and has since returned to his duties in the service of the Miraj State.

The button has not yet passed through, a silk ligature, 6 inches in length, knotted, was attached to the proximal half of the button with the hope of preventing from its falling into the larger viscus (the stomach) which sometimes happens with the Murphy button. From the sensations experienced by the patient, that of something dropping to one side, when he suddenly turns on his left side, I believe the button to be still in the stomach.

An interesting point might be raised as to the cause of the projectile vomiting on two occasions, on the 16th and 28th days after the operation. I am inclined to think it was due to the temporary occlusion of the new gastric intestinal opening by the partial dislocation of the button or the turning of the button on itself on its long axis so as to place the open ends of the button against the walls of the new orifice and thus stopping the open ends of the button as well as the newly-formed orifice. The stomach being distended, pressure by it upon the loop of intestine involved in the anastomosis would also prevent fluid passing through the pylorus beyond the point of anastomosis, and hence the above result.

—o—o—

A CASE OF DEPRESSED FRACTURE OF THE SKULL.*

By SURGN-LIEUT. CLAYTON A. LANE, M.D., Lond, I.M.S.
Jullunder.

ABOUT noon on 17th August 1897, while the 18th Bengal Lancers were encamped at Kushalgarh on their way to Kohat, a sowar was kicked on the head by his horse and was brought to the hospital tent. He was insensible, answering no questions. His pulse was irregular and very easily compressible; his pupils were neither contracted nor dilated and were equal. Crossing the centre of the left eyebrow and running upwards and inwards for an inch was a wound leading down to the periosteum. Above and inside the upper end of this wound a depression could be seen and felt through the skin, and on putting a finger into the wound a fracture was felt starting near the middle of the upper edge of the orbit and curving upwards and finally outwards across the temporal ridge, where it was lost. The curve had a radius of about an inch and the portion of bone in its concavity was depressed, the greatest depression being along the line of fracture, where it amounted to $\frac{1}{2}$ inch. The man's condition seemed to me to be so critical as not to justify my waiting to operate till water could be boiled and cooled, though the water I should have to use came from a dirty tank near the camp. Accordingly

* Reproduced from *The Lancet* by request.

I boiled the solution at once, using carbolic water (1 in 40) for tying and using the instruments provided in the field surgical pack. On starting to enlarge the wound upwards the patient began to struggle, so the hospital assistant gave him chloroform. After trephining and inserting the elevator the depressed bone sprang at once into position and remained there. The bleeding vessels were twisted, not tied, and the skin was sewn up with silver wire without any drain. During the operation he stopped breathing, the pulse being still felt at the wrist, but after artificial respiration had been continued for some minutes he began to breathe again. With the thermometer at over 100° F. in the shade the cessation of artificial respiration was an even greater pleasure than usual. 20 minims of spirit of ether were injected after the operation and he shortly revived. In the evening his temperature was normal and his pulse was 100. The patient was sensible and had no pain.

The question of after-treatment was a most anxious one, as the regiment was to march next day, but after grave consideration I determined to have the patient carried with us on the two marches to Kohat, 30 miles in all, for at that time the chances of his obtaining efficient medical aid at Kushalgarh were more than remote. He was carried in a *doolee* by Kahars, starting at 4.30 A.M. each day and getting into camp before the heat from the sun was great. On the evening of 18th August, his temperature was 100° F., but the wound looked perfectly healthy. On the 19th his temperature was normal and he was quite free from any pain. I left him at Kohat and subsequently heard from Surgeon-Captain BAMFIELD that he never had a bad symptom. He rejoined the regiment about six weeks later. In February last, six months after the operation, the patient told me that he had been quite well since he rejoined the regiment and had had no headache. He had been doing his duty satisfactorily and had not been ailing in any way. There was a slight scar $1\frac{1}{2}$ inch in length above his left eyebrow and on the site of the fracture was a prominence giving the impression that the previously depressed bone had been too much elevated. Where the pit of bone had been removed there was a slight depression and its area, too, was small.

The fact that the wound remained aseptic was probably due to the following reasons, at least in part. So far as the water went, either the carbolic acid was effectual in sterilising it sufficiently to enable the leucocytes to do their work easily or the micro organisms it must have contained were not pathogenic, or if they were so, they were not educated to virulence. The silk supplied in the field equipment is not kept in an antiseptic solution and cannot be kept surgically clean, and I do not believe that silk can be sterilised by a few minutes' soaking in carbolic solution. I accordingly avoided it, twisting all vessels. Before using the silver wire for suturing I rubbed it thoroughly with a clean cloth, hoping that in this way I might be able to get it almost surgically clean, just as one can clean the outside of a catheter. The measures used to cleanse it were probably effectual, for no stitch-abscess resulted.

The case seems to show with particular force the well-known fact that when in the field and away from a contaminated hospital building (as all hospital buildings tend

to become) operations can be successfully performed without all the precautions necessary in a fixed hospital; and though that, of course, is no cause for not taking every precaution which can be taken, still it shows that under these circumstances the risk of septic infection is less than it appears to be, and that it is justifiable, if not an actual duty, to make an attempt to save life even though the surroundings may appear far from favorable.

:O:

THE SCHOTT TREATMENT OF CARDIAC DISEASE.*

By KENNETH STEWART, M.D.

Chapel Street, London, S. W.

A REVIEW of certain cases of cardiac disease which have been treated at Nauheim, or by the Nauheim method, without benefit, leads me to venture on a discussion as to the rationale which governs that treatment.

It is now generally accepted that a portion of the change in the area of cardiac dullness and in the position of the apex beat is due to the altered relations of the lungs and diaphragm to the heart which result from the treatment. There is, however, a real reduction of the capacity of the heart in those cases which receive benefit.

I find that among the numerous explanations which have been advanced to account for the contraction of the organ there is one assumption in common—that there exists some specificity in the Nauheim waters residing in the salts contained therein. I venture to maintain that there is a law of hydrostatics involved which has been altogether disregarded.

The principle to which I allude is the complement to the principle of Archimedes, that "a body immersed in a liquid loses a portion of its weight equal to the weight of the liquid displaced." "Every body immersed in a liquid is subject to a resultant pressure equal to the weight of the liquid displaced." If a body float on the surface of a liquid, the pressure on the immersed portion of that body equals the weight of the body. If a human body be floated in a bath of water, the pressure exerted by the water on the skin and underlying structures equals the weight of the subject.

The result in the case of a living subject is the application of massage to the immersed portion of the body by hydraulic pressure. The effects may be enumerated as follows: (1) Compression of the vessels (arteries, veins, and lymphatics) in all tissues unprotected by the bony skeleton; resulting in greatly increased resistance to the heart's action in circulating the blood, with propulsion of the lymph and venous blood towards the cavities protected by the bony skeleton. (2) The reflex effect on the heart (retarding it) through the splanchnic nerves, dependent on increased pressure on the abdomen from without. (3) The ascent of the diaphragm in response to the increased abdominal tension, a consequent diminution of the long axes of the lungs, an increase in the short axes of the lungs, and a displacement of the heart upwards (resulting in alteration of the relations of the heart and lungs). (4) A reflex action of doubtful existence and degree from the cutaneous nerves. (5) The influence of the temperature of the water in which the body is immersed, varying with its degree.

I do not refer to the other portions of the Schott method; they are "exercises," and have no pretensions to being anything more.

We have evidently in the Schott treatment a new demonstration of the old truth that exercise is beneficial in some forms of cardiac disease, and it is highly doubtful if we have anything more. The balneological treatment is doubtless an ideal one for some cases; the exercise can be perfectly graduated, respiration is free, and the cardiac

beat is well regulated from the splanchnic area—but it may be potent for evil as for good.

There is another lesson to be learnt from a study of the law of hydrostatics referred to, namely, that there are many cases of heart disease which should never be subjected to the strain involved on the organ by immersion of the body in a bath.

:O:

CASES OF BULLET WOUND.*

(UNDER THE CARE OF SURGEON-MAJOR W. C. T. POOLE, M.B. F.R.C.S., A.M.S.)

British General Hospital (No. 3) Nowshera, Punjab.

CASE I.—*Bullet Wound of Left Elbow received in Action in Tirah: Joint Disorganised: Recovery.*—Private S., aged 26, seven years' service, Oxfordshire Light Infantry, was wounded in the left arm on 30th December 1897, during a rear-guard action in the vicinity of the Khyber Pass, about five miles from Lundi Kotal.

The bullet entered the flexor aspect of the left forearm, about 2 inches below the elbow, and came out about 2 inches above the joint on the anterior surface of the arm, fracturing the upper third of the ulna, and disorganising the joint as it passed. He was at first removed to one of the Khyber villages, and afterwards to the field hospital, where the olecranon process of the ulna was excised.

He was transferred to No. 3 British General Hospital, Nowshera, on 7th January 1898. On arrival he was in a very weak and anæmic state; the arm was greatly swollen and oedematous, and both wounds were in a septic condition. Shortly after admission secondary hæmorrhage set in from the upper wound, probably from a branch of the superior profunda artery. It was promptly controlled by a boracic compress and bandage.

Treatment.—The wounds were washed out with a solution of mercury perchloride, 1 in 1,000, and the injured part freely dusted over with boracic acid, covered with boric lint and wool, and the arm placed in a poroplastic splint. All inflammatory action rapidly subsided, and the wounds assumed a healthy appearance. He regained partial use of his arm, and was discharged from hospital and invalided to Netley on 16th February 1898 forty-eight days after admission.

CASE II.—*Bullet Wound of Face received in Action in Tirah: Recovery.*—Private W. O., age 22, service four years, King's Own Yorkshire Light Infantry, was wounded in the face whilst out reconnoitering in the Shin-Kamar Pass in Tirah on 29th January 1898. He was in a stooping position at the time, with his head inclined to the left, in the act of picking up a wounded comrade. The bullet entered the right side of the upper jaw, close to the right ala nasi, passed through his mouth, and came out below the ramus of the left jaw, fracturing the inferior maxilla, and bulging out a small portion of the digastric muscle as it passed. It then entered the upper part of the chest, close to the outer end of the clavicle, and came out in the axilla.

He was transferred to No. 3 British General Hospital, Nowshera, on 14th February 1898, sixteen days after receipt of the injury. On arrival, he was in a weak state, the upper lip and tongue were greatly swollen, his powers of mastication were interfered with, and he was unable to open his mouth wide or to articulate distinctly. Both wounds in the chest were small, but discharged pass freely.

The wounds were washed out with a solution of mercury perchloride, 1 in 1,000; afterwards dusted with boracic acid and boracic wool applied. He made a good recovery, and was discharged. He was invalided to Netley, 16th March 1898, thirty-two days after admission.

THE Indian Medical Record.

1st July 1898.

DRAFT BILL FOR THE AMENDMENT OF THE CALCUTTA MUNICIPAL ACT.

It is well known that Dr. W. J. SIMPSON, late Health Officer, believed that a new Building Act would inaugurate a new era in the sanitary history of Calcutta; certainly the "Draft Bill for the Amendment of the Calcutta Municipal Act," drawn up by the Commission appointed to consider what amendments are required in the law relating to buildings and streets in Calcutta, should go far to realising his expectations, if its provisions are found to be workable, and are properly enforced.

The draft Bill before us is divided into nine chapters as follows:—

1. Preliminary.
2. Streets and Municipal Land.
3. Building Regulations.
4. Bustees.
5. Privies, Latrines, Urinals, etc.
6. Acquisition and Disposal of Land and Buildings.
7. Miscellaneous Provisions.
8. Demolition, Alteration and Stopping of Work.
9. Penalties.

Under Chapter 2, the fullest powers are given to the General Committee in all things pertaining to streets as follows: Sec. 8. The General Committee, with the sanction of the Corporation, may—

- (a) lay out and make new streets;
- (b) construct new bridges and sub-ways;
- (c) turn, divert, discontinue or permanently or temporarily close any public street or part thereof; and,
- (d) widen, open, enlarge or otherwise improve any public street.

Sections 9 to 19 deal with the modes of procedure in each of these cases.

Sections 20 to 23 deal with private streets, and gives the General Committee power to enforce their being properly levelled, paved, metalled, flagged, channelled, sewered, drained and lighted, as well as laying down provisions for the level, width, and height of buildings abutting on any new private streets that may be constructed.

Sections 24 and 25 deal with the acquisition of land. Sections 26 to 30 with prohibitions and directions with reference to the construction of verandahs, balconies, sunshades, weather frames, etc.

Section 30 gives the power to construct Bye-laws, when found necessary, in the carrying out of these matters.

Sections 31 to 34 deal chiefly with the size, shape, situation and drainage of building sites.

Sections 35 to 40 with buildings generally; wherein power is given to regulate future erection of certain classes of buildings in particular streets or localities; thus the erection of buildings of the warehouse class, or if huts will not be allowed without special sanction, while

the elevation and construction of the frontage of all masonry buildings must be suited to the locality in respect to their architectural features.

Sections 42 and 43 are long and important sections; they detail clearly and adequately all the requirements for the construction of dwelling houses. Not more than two-thirds of the site may be built over; all walls must have a damp-proof course; every room must be open to the outer air; the size and ventilation of inhabited rooms is prescribed; the area, width, and level of the inner court yard is laid down; no rooms are to be built over privies; and a certain open space about all houses is insisted on.

Councils of perfection are here found in plenty, if they are carried out, Calcutta will, in some future day, present a very different appearance to what it does at present.

Sections 46 to 59 deal with applications for approval of sites for, and for permission to erect, re-erect or materially alter masonry buildings. Any person wishing to do any of these things must get the permission of the Chairman and supply him with the fullest particulars.

Section 56 lays down the grounds on which permission may be refused.

Sections 60 to 63 provide for the supervision over erection, re-erection and material alteration of masonry buildings.

Sections 64 to 73 discuss the provisions applicable to huts hereafter erected, re-erected or materially altered, the sizes of passages, courtyards and spaces between huts is carefully defined.

CHAPTER IV. BUSTEES.

Sections 79 to 98 deal with the improvement of bustees. Power is here given to the General Committee to call upon the owners to prepare a standard plan of the bustee showing the manner in which the bustee should be laid out; if the owners do not comply within 60 days, or prefer to have a plan prepared for them, the General Committee shall prepare the plan.

During the preparation of the standard plan all building will be stopped, and all future building must be in conformity with it; the General Committee may further, on paying compensation, require the owner to take down any hut not fulfilling the conditions of the standard plan and may force the owner to construct drains, privies, passages, etc., and to deal with any tanks as prescribed.

Should this procedure appear to be too dilatory, in view of the insanitary condition of the bustees, the General Committee may direct two medical officers to report upon it, to provide a plan, and to certify which of the improvements required to bring the bustee into conformity with such plan should be taken in hand forthwith, in consequence of the unhealthy condition of the bustee and which may be deferred. Six months is given to the General Committee to approve this plan, and then they may require the owners to carry out the necessary improvements. If the owners do not comply, the Committee take the matter in hand.

Sections 99 to 108 are quite new and deal with the re-allotment of bustees. The Commission say:—"As far as we can see, they are likely to work well in practice, but we think it very desirable that public opinion should be specially united with regard to them."

Section 99 says:—"The Corporation, at the instance of the General Committee, may give public notice of their

intention to resit the land comprised in any bustee, or in any portion of a bustee which is contained between streets so as to form a block." A ground plan must be prepared and a copy sent to each of the owners.

The chief difficulties likely to occur, and to obstruct the Corporation in this laudable endeavour will doubtless be in connection with the questions of estimated value, the re-division of the re-allotted bustee amongst the different owners, and the question of compensation.

The owner, if dissatisfied with the valuation of his plot, may apply within a month to the Chief Judge of the Court of Small Causes. His judgment shall be final.

When a re-allotment plan has been finally adopted for any bustee or block, the General Committee shall cause the huts thereon to be removed at the cost of the Municipal funds.

The procedure appears to be as follows.—

1. The plan is to be prepared by the General Committee.
2. The Corporation gives public notice of their intention.
3. On the publication of this notice, a copy of the plan is to be sent to each of the owners, together with a notice requiring him to appear before the Committee within a month if he is not satisfied with the valuation of his property.
4. The Committee, after hearing all objections, shall serve a notice specifying the valuation arrived at.
5. If the owner is still dissatisfied, he may within one month apply to the Chief Judge of the Court of Small Causes.
6. When the value has been settled, the re allotment plan shall be prepared.
7. It shall then be carried out by the Corporation removing the existing huts.

It appears from this, that the time required to introduce such a radical change as to sweep a whole bustee off the face of the earth, is two months plus the time required for the construction of the plans.

Chapter V. deals with privies, latrines, urinals, etc., and comprises Sections 109 to 125.

All these sections are of the greatest importance, but it will not be necessary to review them in detail; they lay down regulations for the site; access from the street; ventilation; drainage and construction of floors; distance from water supply or tank.

Section 119 lays down that "all privies and urinals shall be under the survey and control of the General Committee as regards their site, materials, dimensions and construction, and powers are given to the Committee to enforce their requirements.

The working details of Bills of this description are notoriously difficult to carry out, they clash with many interests, and the general unwillingness of house owners to spend money on their property affords a fruitful source of obstruction; the law is invoked and its delays are proverbial. A strong governing body is however all that is required, and we trust that Calcutta may be fortunate enough to find itself possessed of such a one.

IS QUININE A UNIVERSAL MALARIAL SPECIFIC?

DR. J. G. VAN MARTER of Savannah, U.S.A., publishes some important observations on "Quinine in Malaria, excluding the Simple Intermittents," in *Galliard's Medical Journal*.

"There is a vast difference," he says, "between the action of quinine in the intermittent malarial fevers and its action in the continued malarial fevers."

He considers that it is "high time that a protest be issued against the general acceptance of the views of OSLER, THAYER and other northern clinicians on the specificity of quinine."

"Under quinine the forms of the ordinary cycle of development, disappear rapidly from the peripheral circulation, but the crescentic and ovoid bodies remain a much longer time, sometimes even for months."

"OSLER, THAYER, COUNCILMAN and others in the North speak truthfully when they say that quinine is a true specific against the malarial parasite and the malarias which have come under their observation, but these gentlemen have not studied malaria in its true home, in a climate fitted for the development of the most virulent parasites, with infections occurring the year around. In such climates, he holds, that quinine is useless as a prophylactic, as it cannot be taken indefinitely the year around in doses sufficient to kill the parasite as fast as it develops."

"Now, coming to the treatment of malaria (and, of course, I am always speaking of the severe infections and leaving out of the question the intermittent fevers), is quinine a true specific? No, there are cases innumerable in which the patient would die, did we not add other potent drugs to our quinine, or for a time at least attach more reliance on other drugs than quinine, that we are inevitably led to the conclusion that although a true specific against the plasmodium of tertian and quartan fever, it is not a specific or antidote to the parasite of the more severe continued malarias and the toxins generated by them. With patients in whom the microscope has shown the disease to be malaria in any of its forms, quinine is a specific in all those with intermissions or with marked remissions; not so, however, where the fever is continued, or in those malarias with but little temperature.

"Dr. PLEHN, a German physician practising in the Cameroons on the West Coast of Africa, and in what is probably the most malarious region of this earth, has observed that quinine is a good preventive and the best for treatment in new-comers and those not long resident in that region, but in spite of 5 grains per diem, practically all foreigners get the fever, and the large majority die of it sooner or later.

"In all these cases, with the exception which I shall hereafter note (the hæmaturias) quinine is given in enormous doses, with calomel (which, by the way, is never omitted) and stimulants, but while the actual paroxysm is overcome by the quinine (if the case be seen in time, or not too malignant), the spleen remains large, the crescents remain in the blood, and malarial anaemia sets in.

"This observation shows—

"(1). That quinine is a specific against the protozoa of tertian or quartan malaria.

"(3). That quinine alone has no action on the toxins produced by grave malarial fever which calomel has twice the potency (at least in full physiological doses).

"(4). That quinine, even as a prophylactic, cannot be indefinitely taken.

"(5). That quinine has no effect whatsoever on malarial anemia (really a chronic toxemia).

"Still another variety (more correctly complication) of malaria, hæmoglobinuria, is made worse by quinine. I believe that the great majority of those practicing in countries where severe malarial exist, will confirm the observation that quinine makes it worse. THAYER admits that quinine never shortens an attack of hæmoglobinuria, but says it prevents a recurrence—this latter being an assertion without any warrant of experience, and I know it to be wrong. Quinine is a frequent cause of hæmoglobinuria, and after one attack, if quinine be taken, is very apt to cause the condition which THAYER says it will prevent.

"In my experience the cases of malaria (as proven by the microscope) in which quinine failed to cure—hence did not act as a specific—have been confined to two types. First, and most common, severe malaria subcontinua typhoides (an æstivo-autumnal form), where the fever ran along for days with very slight remissions, and second, those irregular forms, sometimes seen where, with undoubted malaria, the fever of a continued type is low, seldom above 102, the symptoms presented are those of a profound toxæmia resembling uræmia; suppression of urine, jaundice, delirium, subcutis, without chills or paroxysms of any kind.

"I will observe here that there are cases of both types, above mentioned, that would surely die, did we not add other drugs to our quinine, and that a large proportion of cases for a time at least are better off without it. We must recognize that in these types we have a toxæmia to deal with, and it is just this toxæmia which I claim is unaffected by quinine.

"In treating these very severe malarial toxæmias as we see them in the country or plantations just out of town, or if nearer, only in the suburbs, or on river shores, we are placed at a great disadvantage as regards doing the best possible for our patients. Perhaps in these very cases if our patients could be moved away from an atmosphere whence constant reinfection is taking place, and taken to a grand hospital like the Johns Hopkins, in Baltimore, where the poor even can obtain luxuries, and under skilled trained nursing, perhaps in such cases quinine might help our patient, if proper eliminative treatment were added, (for it would not without it); but how is it with us, the patient in a miserable hut, or poor farm house, not a bath tub for miles, no clean bed linen, no decent drinking water, no chance of proper food or good nursing, and an unalterable opposition to hospitals in general, it is in these cases that we have to practice, for it is only amongst such that we see most of our severe malarial, and if quinine were a specific, they

would all be cured before we ever saw them. They all take plenty of quinine dissolved in water, and with it calomel.

"I have tried, in the severer cases, quinine intravenously, and must say that it does not well, that it is the only way to give it in the severest form, but it does not shorten the course of the fever; it seldom breaks it up, as it should if it were a specific.

"There is one way of giving quinine by the mouth, of particular efficacy in many of the severer cases, and that is WARREN's tincture, and, to my mind, it is a most excellent medicine."

CONCLUSIONS.

"1. As a preventive quinine will not do for those who are compelled to live indefinitely in a severe malarial climate; in time acting as a vaso-motor poison.

"2. Quinine acts nearly as a specific in all malarial fevers characterized by intermissions or well-marked remissions, but fails in the continued fevers, those with typhoid-like symptoms, those malarial without temperatures, and the cachexias and anemias due to malaria.

"3. Proving thus that quinine is a poison to the plasmodium itself, but useless against the toxins manufactured by it.

"4. That WARREN's tincture in the last condition has an action not yet understood, on the toxins (or the eliminative system) by which the system is put in a condition to benefit by quinine.

"5. That quinine should never be used in hæmoglobinuria, or given subsequently, to one who has suffered from it, being liable to bring about a recurrence of the condition.

"6. Only those living in regions of severe malaria can become competent to settle these questions pro or con."

A perusal of Dr. MARLEN's interesting paper suggests to us the following —

There are two generally acknowledged tests for doubtful cases of malaria—one the finding of the plasmodium in the blood—the other, the effect of quinine upon the course of the fever.

It appears, however, that there is a large class of cases where the plasmodium is found in the blood, and yet where quinine has no appreciable effect.

From this it follows either—

(1) That the plasmodium is found in cases which are not malarial; or

(2). That quinine is not a universal malarial specific.

We believe that plenty of malarial fevers are met with in such stations as Mean Meer and Peshawar, which are not amenable to quinine; these would provide excellent material for interesting clinical observations.

We have heard of regiments leaving Peshawar, at the beginning of the cold weather, in the usual course of the annual reliefs, which were to all appearances saturated with malaria and quite unfit for any arduous duties, yet which completely recovered their health under the invigorating influence of daily marches and the exposure to fresh air.

MANSON'S MANUAL OF THE DISEASES OF WARM CLIMATES.

Dr. PATRICK MANSON, M.D., LL.D., has succeeded in so thoroughly identifying himself with English tropical medicine, that a book from his pen is, *a priori*, certain of a wide welcome; and it cannot be said, for the reputation of the English School, that his "Tropical Diseases" has appeared a moment too soon.

How poor our literature is in this respect may be judged from the fact that there is only one other work to span the immense gulf between the pre-bacillary days and the present time with its multitude of pathogenic organisms; a period in which the whole pathology of disease has been revolutionised and reconstructed.

From DAVIDSON's treatise on the "Diseases of Hot Climates," "Tropical Diseases" by Dr. MANSON differs in one very important respect; for, while the former discusses a limited number of the best known diseases only, and especially those to which Europeans are subject, the latter, in wider flight, tries to embrace the whole pathology of warm climates, and to bring within our ken all known disease, whether peculiar to the native or shared alike by him and the European.

In this respect the book is unique and marks an epoch of its own; it however gains this distinction at the expense of fulness and completeness of detail, which would be quite impossible in a work of its size, extending as it does to no more than 600 small pages.

It may be fairly considered as a short and concise manual of the better known diseases, and a guide or index to the little that is known of the rarer pathological conditions, amongst which we note "Nasha Fever," "Kala Azar," "Ponoc," "Verruga Peruana," "Craw Crawl," "Pinta," "Goundou," etc.

It will no doubt serve to excite interest in these obscure affections and in a more general way to give an impulse to the exact study of tropical medicine.

The book is divided into seven sections, the first deals with "Fever"; the second with "General Diseases of Undetermined Nature" as *Beri-beri*; the third with "Abdominal Diseases," including Cholera, Abscess of the Liver, etc.; the fourth with "Infective Granulomatous Diseases"; the fifth with "Animal Parasites and Associated Diseases"; the sixth with "Skin Diseases"; and the seventh with "Local Diseases of Uncertain Nature."

A chapter on the "Aetiology of Tropical Disease" forms the introduction; this gives us the clue to the stand-point from which Dr. MANSON regards all tropical diseases, he does not travel round his object and view it in all its possible aspects, such circuition is not to his taste; his sole point d'appui is the germ, and his only guide the microscope.

The whole subject, in its present state, is much too wide for this narrow limitation, nor do we think he is successful in the reasoning by which he tries to justify his attitude.

He asks: "In what way do tropical influences affect disease, and why should it be that some diseases are peculiar to tropical climates, or are specially prevalent in such climates?"

We may mention parenthetically that by "tropical" Dr. MANSON simply means "warm."

In reply to the above he tells us that "The European, it may be, on his first entering the tropics, and until his

machinery has adjusted itself to the altered surroundings, is liable to slight physiological irregularities. A predisposition to certain diseases, and a tendency to degenerative changes, may be brought about in this way; but acute disease with active tissue change is not so caused. In the tropics, as in temperate climates, in the European and in the native alike, nearly all disease is of specific origin. It is in their specific causes that the difference between the diseases of temperate climates and those of tropical climates principally lies."

"Modern science has clearly shown that nearly all diseases, directly or indirectly, are caused by germs. It must be confessed that although in many instances these germs have been discovered, in other instances they are yet to find; nevertheless, their existence in the latter may be confidently postulated."

These are very wide and sweeping statements, but we are far from accepting without demerit either their assumptions or their logic.

This talk about the physiological machinery adjusting itself is mere trifling, while to maintain that climatic influences can induce degenerative changes, but not acute disease with active tissue change, is a distinction altogether too fine and artificial for our taste; the final word on these subjects has not yet been said; they belong to a field of research which has not yet been exhausted, and without some more reliable data we are not inclined to accept these dicta.

Considering, on the other hand, that the number of diseases in which a germ has not been found, far exceeds the number in which it has, we would ask is it logical, is it rational, to argue from the few to the many, from the particular to the general, and can science and truth derive any advantage from such false methods?

We cannot for the life of us see what advantage is to be gained by this universal germ worship. We know that there are plenty of forces in nature inimical to life, whether animal or human, numberless poisons, extreme heat and extreme cold, there may be many others whose nature and existence are still unknown to us, surely it is as unwise as it is unreasonable to assume that every malevolent influence, whose nature is still obscure, is some germ or the product thereof. An open mind should be maintained on these points, and advance can only be made by the careful investigation and weighing of every possible factor.

It is one of the defects of the bacteriological school that they are too fond of putting forward hypotheses and expecting others to accept them as facts, hypotheses are doubtless very useful things, in their proper place; they subserve the purpose of Aunt Sally at a fair, to be shot at and knocked down, like her, they invariably come up smiling as if nothing had happened. What we want is a little more proof and less, far less, hypothetical conjectures.

As Dr. MANSON is known to us as a past master in the art of medical fiction, we naturally look for some show of talent in this direction, and we are not disappointed, in discussing the peculiar distribution and limitations of certain tropical diseases as *malaria* we find the following:—

"Lastly, I can conceive, and believe, that there is another and less directly-acting set of conditions influencing the distribution of disease . . . The malarial parasite

is absent in many places in which, apparently, all the conditions favorable for its existence are to be found in perfection. Why is it not found there, seeing that it must certainly have been frequently introduced? I would suggest that in some instances this, and other disease germs, or the organisms subtending them, are kept under by natural enemies which prey on them, just as fishes prey on and keep down water-haunting insects, or as mice do humble bees." Unfortunately we have not the faith of the *British Medical Journal* to exclaim "This is scientific medicine!" It may be balderdash for all we know.

Malaria, as its importance demands, is allotted a larger share of the book than any of its companions; 126 pages are devoted to it; in these the malarial parasite occupies a prominent place. We regret to note that Dr. MANSON, while admitting the scientific incorrectness of the name plasmodium, adheres to it in preference to hæmatozoon, the name originally given to it by LAVEHAN, its discoverer.

"It is now practically certain," he says, "that the presence and proliferation in the blood of this parasite is the cause of malarial disease." "Hitherto all attempts to cultivate the parasite, whether in the ordinary culture media or inside the bodies of the lower animals, have failed. Until this has been successfully effected, and until experimental infection of man from a pure culture has been followed by typical malarial disease, absolute proof of the causal relationship of the parasite to the disease may be said to be wanting; short of this, however, proof is complete, and, as already remarked, the plasmodium may, with confidence, be accepted as the cause of malaria."

KOCH, as we all know, laid down certain canons probably with the laudable intention of checking the grasshopper instincts of two ardent bacteriologists; it now appears to be the proper thing, when these canons present difficulties, which are not readily surmounted, to cast them aside as of little value, short of absolute proof, proof is complete, is the somewhat contradictory expression in which the verdict is broken to us, and of course we must be satisfied.

MANSON'S HYPOTHESIS.

"The plasmodium," we are told, "like all true parasites, must be adapted not only for a life inside its host but also, in order that its continuance as a species may be assured, for a passage from one host to another. Consequently it exhibits two distinct phases—an intra-corporeal or human phase, and an extra-corporeal phase. Clinical observation makes it certain that there is yet another phase—the latent phase."

Next we are told that "As it is unreasonable to suppose that an organism which propagates so actively in the human body has no opportunity, either by passing from one host to another or in other ways, of continuing its species, we are forced to conclude that some provision must exist in the economy of the parasite that enables it to leave and enter successive hosts."

"The problems suggested by these considerations are: First, how does the malaria parasite leave the human body to get a chance of following an extra-corporeal life? Second, what is this life? And third, how does the parasite enter the human body?"

MANSON'S hypothesis is, "that the flagellated body con-

stitutes the first phase of the extra-corporeal life of the plasmodium."

We are told that, "the flagellated bodies are developed from two forms of the intra-corporeal parasite—namely, in certain types (the malignant) of malarial infection from what is known as the 'crescent body'; in other types (the benign) from certain large intra-corporeal plasmodia," and that they are never seen in newly drawn blood.

Now what are these "crescent bodies" in which is allotted such an important rôle? Up to the present nothing is known of their true nature, and there is much difference of opinion amongst the authorities. MANSON, however, is inclined to agree with MARCHIAVA that the "crescent body" is the result of the conjugation, the forming together of two ordinary plasmodia, so that a single plasmodium is not capable of forming flagella, but two together are, as to the why and wherefore of this we should like some further explanation.

But worse than this it appears that a number of high authorities, among them MARCHIAVA, BIGNANI, BLANCHARD, etc., regard the "crescent bodies," spheres, and flagellated bodies as being degenerated dead or moribund plasmodia. These observers have had excellent opportunities for forming their opinions, and should it happen that they are right, MANSON'S edifice topples to the ground.

The whole mosquito theory turns on the simple question whether these bodies are living or dead, and we think it would be well if this point were decided before the mosquito theory is taken as grand serious.

THE PARASITE IN CONNECTION WITH DIFFERENT TYPES OF FEVER.

We find that "a particular clinical type of malarial disease is associated with a parasite of more or less definite morphological form and intra-corporeal life cycle."

The parasites are divided into two groups—the benign and the malignant.

"The benign are of two kinds, one having a cycle of 72 hours, causing a fever recurring every three days—quartan ague; the other with a cycle of 48 hours, causing a fever occurring every two days—tertian ague."

"The malignant parasite has at least three forms: A pigmented parasite of 48 hours' cycle; a pigmented parasite of approximately 24 hours' cycle; and an unpigmented parasite, also approximately of 24 hours' cycle."

Any one of these five kinds of parasites may cause what is known as remittent fever. The intermittency or remittency of any fever depends in a great measure on the simultaneousness or the reverse of the maturation of the crowd of parasites giving rise to it. If all the parasites present are of nearly the same age, they mature approximately simultaneously, and we have an intermittent; if they are of different ages, they mature at different times scattered over the 24 hours, and we have what is known as a remittent.

Further, two generations of tertian parasites maturing on successive days will produce a quotidian fever, tertiana duplex; two generations of quartan parasites maturing on successive days will produce fever fits on two successive days followed by one day of freedom, quartana duplex; three generations of quartan parasites will produce what clinically appears to be a quotidian fever, but in reality is a quartana triplex."

"This is delightfully clear, it is absolutely perfect, and as simple as an easy sum in arithmetic."

The most marked feature of all malarial fevers is periodicity, and the whole question of periodicity, according to the new doctrine, depends upon nothing more complicated than the age and period of maturation of the parasite or parasites. Each variety of parasite has its own special life cycle, and the process of maturation occurs at regularly recurring intervals of 72, 48 or 24 hours, and coincident with maturation is the accession of fever.

So far so good, but see here what an overwhelming difficulty this amazing simplicity lands us.

A man with a double tertian has two different families of parasites in his blood, one family 24 hours older than the other; thus each day one family matures, so that he has an accession of fever every day.

Now each of these families may have gained an entrance to his blood either at the same hour, or at any other hour during the 24 that make up the day and night; the chances are strongly in favor of their gaining admission at different hours, and supposing one to have entered the blood at 7 p.m. and the other at 7 a.m., then the infected individual should have an accession of fever every alternate day at 7 p.m. and every other day at 7 a.m.

Has any one ever observed a double tertian presenting these characteristics, i.e., the fever coming on at distinctly different times on the different days? No; this has not been observed, and Dr. Manson admits that, "As a rule, the attacks tend to occur about the same time every day."

This is clearly absurd, considering the stress that is laid upon the cycles of the parasites, and it follows that either that the cycles of the parasites is not as represented, or that their period of maturation has no causal connection with the fever accession.

When we come to consider the case of a man having three different families of quartan parasites in his blood, the chances (that their ages would vary by each interval of 24 hours, and that each of the three would gain admission to the blood at exactly the same time, are enormously diminished. Yet we must shut our eyes to the doctrine of chances and swallow all this if we are to believe in this theory in its entirety.

How does Dr. Manson deal with this difficulty? Having laid down the life cycle of each parasite, and told us that, upon the length of this cycle depends the clinical type of the fever, he says: "But how are we to account for the periodicity of the parasite itself? It is true that it has a life of 24 hours, or of a multiple of 24 hours; but why should the individual parasites of the countless swarms conspire to mature at or about the same time?"

Yes, undoubtedly this is the crux! Why on earth should they? The chances are undoubtedly all against it, and now read the explanation, or rather the answer, for explanation, there is none.

"That they do so," we are told—"not perhaps exactly at the same moment, but within a very short time of each other—is a fact, and it is one which can be easily demonstrated."

We have before been told, as a fact, that each parasite can only mature at a certain well-defined time. Now we are told, as a fact, that each parasite can mature at any time; but two facts which contradict each other cannot both be true. Q. E. D. And here for the present we leave the question.

THE PRESENT POSITION OF THE THEORY OF MALARIAL FEVERS, BY DR. J. H. A. MANSON; RESIDENTS TRAVELING FROM MONTREAL RECOMMENDS WASHINGTON.

The treatment of the infectious diseases has reached a turning point. Since the bacteriological researches of the last few years have made known to us that the causes of these diseases lie in the presence and multiplication of the most minute forms of life, the so-called pathogenic micro-organisms, there has been a transformation in therapeutics. The result is that now the active cause (Indicative Causalis) strives to assume a more important position than the symptomatology (Indicative Symptomata). This struggle has only just been decided for one infectious disease, viz., diphtheria, and certainly in favor of the Indicative Causalis.

With regard to other diseases we must put our trust in the future, that it will be fulfilled we have no doubt, for the realization of this hope is the logical outcome of our knowledge of etiology. Nevertheless we are very far from being such therapeutic enthusiasts as to believe that with the victory of the "Causal indication" we can altogether lay aside the consideration of the symptomatology which has previously had a leading position.

On the other hand, the more we learn to know and understand the therapeutical errors of our forefathers, the more is the conviction forced upon us that they will, in a great measure, maintain their position in the future, and that we shall only reap real and valuable results by combining and mixing both old and new methods.

But the causal-connection assumes greater prominence as bacteriological research extends; from it we have learnt that in the majority of diseases due to bacteria, it is not the bacterium, the bacillus, or the coccus per se which causes the onset of the sickness, but the metabolic toxins produced by them.

The etiological treatment must therefore consider the intoxication as well as the primary infection.

Hence with the advance of therapy, new questions arise, and in addition to the struggle with prominent symptoms which has hitherto been the chief object of therapeutic measures it becomes necessary—

(1). To destroy the cause of the infection, the product of the toxine; (2) to eliminate from the body the toxin that has already gained an entrance, or (3) to neutralise it in the body and render it inert; and lastly; (4) to immunise the body against subsequent infection, i.e., to check development of toxins in the future.

The first task, the destruction of the cause of the infection, is a local indication, according to the mode of ingress of the virus it may be a surgical operation or an internal one.

The second task, to eliminate the toxin that already is in the body, rests upon empirical knowledge, as far as experience goes, an undoubted improvement follows the eliminative method, whether the poison be eliminated by the intestines, the kidneys, or by the skin.

Only quite lately the newest researches have thrown a light upon the long-accepted facts of septicæmia and by means of experiments on animals demonstrated the active toxins in the excretory products of the above-named organs.

With the object next to neutralise the toxin in the body and prevent its action, it is the province of serum therapy to deal. This is the newest step, we can already say, the most hopeful direction of therapeutic methods. It is founded on the knowledge that in the blood serum of individuals who have recovered from infectious diseases, a material is found which has the effect of a medicinal antidote or a medicinal poison (e.g., oxide of iron in arsenic poisoning), the so-called anti-toxins; concerning their mode of action the details are not yet quite clear. Having discussed the subject of tetanus, we will return to the consideration of the question and the hypotheses that have been built up.

The fourth and last question occupies itself with the prophylaxis against subsequent infection, to immunise the body and make it unsusceptible to the effects of toxic substances.

We call this method universal preventive treatment.

The prophylactic serum injections in diphtheria show us its daily application and wonderful effects.

Vaccination against small-pox forms a well-known analogy, its aim is to immunise the body, but its *modus operandi* is different; for through vaccination a local variola is caused whose object is to immunise the body against a general infection.

When we have found out the exciting cause of this disease, perhaps vaccination will have to give way to the safer and more effective method of serum therapy.

Of the infectious diseases whose treatment has undergone a complete transformation in the last few years, after diphtheria, tetanus is the most prominent. In journals devoted to the new literature we certainly read of serum therapy applied to a series of infectious diseases, as measles, scarlet fever, pneumonia, typhus, it is not improbable that this method of treatment has a future before it, especially when fresh discoveries have been made concerning the exciting causes of these diseases, the nature of whose infection is as yet unknown; but the result of this treatment up to date are so obscure and doubtful, and the observations as yet so few that it is impossible to give a decided opinion on the subject.

On the other hand, during the last few years, tetanus has become a very lively ground for discussion, and a series of anti-toxins are already in the market, associated or not with which fact, a great number of published results exist.

It may therefore be of interest, considering the extraordinary severity and practical importance of the disease, to form a new estimation of its treatment.

Let us also contemplate the general features of the therapy of traumatic tetanus with reference to the above questions, and take a clear view of the therapeutical indications.

¶ We next turn to the symptomatic treatment, and we may be permitted briefly to set forth the symptoms of tetanus. We notice that following upon an external wound, after a known incubation stage, which for the estimation of the severity of the case is of special importance, spasms of the body appear.

According to Ross, by far the best informed authority on tetanus, there are five stages of these. In the first, spasm of the muscles of mastication appears, Trismus. In the second, spasm of the neck, ophiotonus, spasm of

the abdomen, of the knees, and feet. In the third, these permanent tonic spasms are interrupted, without any external cause, by regularly recurring contractions of the affected muscles, the so-called shocks or "crises" of the French writers. In the fourth, appears the abnormal excitability of the reflexes which leads to vehement spasms through contact or through any movement in the neighbourhood.

To these stages, which, on the whole, present a satisfactory picture of the disease, Ross adds a fifth, the stage of exhaustion which succeeds the first four and generally leads to death. Death occurs in the majority of cases by suffocation in consequence of spasm of the muscles of respiration, of the glottis and diaphragm.

Regarding the severity of tetanus, we readily accept Ross's division of such cases. Those that occur within ten days of the wound are severe, and the mortality amongst them is very high; those that appear later are mild. Amongst the severe cases there are some whose symptoms develop very quickly in a few hours or days; these we class as very severe, and those which develop gradually as middling severe.

From the general nature of the symptoms and of the tonic spasms with their complications we see that the question of therapy has to deal with remedies for insuring quiet and relaxation. Therefore the question of narcotics has to be specially considered; for this condition Ross places opium, especially in the form of hydrochlorate of morphia, before all remedies; this preparation is the only constant one, and it is easily soluble. On the other hand, opium varies in its proportion of morphia. According to recent analyses, from 1.5 to 28 per cent.; moreover, its reception by the stomach is rendered difficult, and this explains the enormous doses that have been given without producing symptoms of poisoning. Thus 5.0 7.0 30.0 grains a day have been given instead of the maximum dose of 0.5. Ross therefore always gives morphia. We have seen very favorable results from the subcutaneous injection of opium in a very severe case, which we will mention here in detail.

ADAM R., 10 years old, the son of an agriculturist.

Twelve days before his admission he was thrown from a wagon on to the ground. The wheel struck him on the outside of the left knee and raised a flap of skin as big as of the palm of the hand. This was stitched on again by the physician after a pretended, hasty disinfection. The wound suppurated, the flap necrosed, and the skin in the neighbourhood became gangrenous, the boy was unable to give any more precise details, but he declared that even a few days after the accident he was unable to close his mouth and eyes as freely as formerly, nor was he able to swallow his food so well.

These troubles became worse during the two days of his stay in hospital.

Condition: 17th May 1895.—A slenderly built anæmic boy. Anxious expression of face. Eyes slightly closed. Mouth distorted as if about to cry. Can only open or close it to the width of 2 cm. No inflammation of the throat. The muscles of the neck tense. Holds the upper part of the body stiff when held erect. No movement of the head backwards and forwards. Patellar reflex lively. Ankle clonus. Lungs and heart normal. Abdomen retracted, tympanitic. Motions regular.

In the region of the left knee an almost circular portion of skin, with a diameter of about 14 cm. has been removed apparently by necrosis; the surface is granulating well; the edges are as yet not quite healthy. To the inner side of the patella, the joint is exposed in a white surface, the size of a bean, partly covered by granulations.

Over the talar condyle of the tibia there is a flat fluctuating abscess with discolored skin about the size of the palm of the hand. The left leg is somewhat bent at the knee. There is no fever.

Diagnosis.—A fairly healthy skin wound of the left knee, an extra articular abscess over the tibia. Commencing subacute traumatic tetanus.

18th May.—No fever. The granulating surface was dressed antiseptically, the abscess opened, and a quantity of implanted pus evacuated. The general health appeared good. Sleep quiet. Spasm of the muscles of the face and neck increasing.

19th May.—No change. Appetite good, moderate, difficulty in swallowing. Head symptoms unaltered. Ordered perfect rest, moist air, chloral hydrate.

20th May.—Greater difficulty in swallowing. Mouth can scarcely be opened a finger's breadth. The tongue can hardly be protruded beyond the teeth. The eyes can be opened a little better. Lifts himself with difficulty and with great pain in the neck.

21st.—The temperature previously normal rose yesterday to 101.4°F.; it is the same to-day; morning remission below 98.6°F. Spasm of the neck pronounced. All the muscles of the neck feel hard.

He cannot be raised on account of the great pain. The pectoral muscles are tense and hard, so that passive motion of the arm meets with great resistance. The tetanic spasms are permanent and are not excited reflexly. Knocking on the bed or even on the body gives rise to no paroxysm, but little sleep last night; by fits and starts a peculiar cough is given during which the boy often bites his tongue. During short periods of sleep a cry is given out, after which the child awakes crying. Ordered, in addition to the chloral hydrate, Tinct. Opii. Simp. 3 drops frequently subcutaneously.

22nd.—The wound is unhealthy and secretes a greenish pus; otherwise no reaction. During the day the boy lies fairly quiet in bed, the head drawn back, the body stiff, the eyes still almost closed. Trismus is well marked. The tongue previously bitten can now scarcely be moved. Any attempt to sit up causes great pain. The head can be moved sideways. No paroxysms produced reflexly to-day. Reflexes of the lower extremities heightened. Ankle clonus more marked. Difficulty in swallowing more pronounced; only liquid nourishment can be taken. No fever this evening. Stools and evacuation of urine normal.

To-day his parents came to visit the boy, and on being questioned said, that for two days before he was taken to hospital his expression had undergone a remarkable change; his eyes were always closed and already difficulty in swallowing had appeared.

23rd.—The muscular spasm is now most marked in the muscles of the breast and in the extremities. The spasms were relieved for a time by an injection of opium and the movements became freer; the stiffness of the neck alone remains permanent.

On attempting to cough the patient frequently takes the tongue which has immovable wounds.

Towards mid-day a very severe spasm of the diaphragm occurred with strong trismus, the lips became blue, breathing almost ceased, artificial respiration was necessary. After this the breathing became re-established. No paroxysms of the larynx. No change in the wound.

24th.—No sugar or albumen in the urine. Temperature 102.2°F. General spasms unaltered. Any effort at active movements brings them on, sometimes in the extremities, sometimes in the pectoral muscles. The patient complains of pains in all his limbs. The spasm of the diaphragm has not recurred; the muscles of the face are more relaxed and the difficulty in swallowing is less. The trismus is not so marked.

25th.—Chloral hydrate can no longer be taken, as it excites cough. Bronchial and tracheal sounds loudly audible. The phlegm cannot be expectorated on account of the persistent trismus. The breathing is regular. Under repeated injections of opium the spasms are less, reflexly they can only be excited by loud noises, not by knocking the bed or by touch. Temperature 100.4°F. Pulse regular, strong. Urine and stools passed naturally. The muscles of the chest and abdomen are stretched and hard. The head drawn back through the spasm of the neck muscles. The anxious expression is not so marked as at the beginning. Fluid nourishment can be taken.

27th.—Condition almost unchanged. In the afternoon there were two attacks of spasm of the diaphragm, in one of these the breathing suddenly stopped, the mouth was firmly closed in the drawn back head, the teeth were clenched, so that the jaws could only be opened with difficulty with a forceps and by the removal of several teeth, the lips were blue, the pupils dilated, the whole body stiff. Artificial respiration after the tongue was drawn forward; the spasm of the thorax was difficult to overcome, so that it was some time before air could be induced to enter the lungs, after the lapse of 1½ to 2 minutes the first effort at respiration took place, but the breathing was for the next hour stertorous and spasmodic, the respiration prolonged with loud rales, frequency about 40 to the minute.

The treatment was Tinct. Opii three or four times hypodermically, so that the patient was kept in a light opium slumber. A fair amount of albumen in the urine. Experimentally 1gr. was injected into a mouse.

28th.—Yesterday towards evening there was another spasm of the diaphragm associated with general tetanus. Extract of opium continued subcutaneously. The general appearance is no worse; the movements of the face are freer; the mouth can be opened 1½ cm; the tongue as yet cannot be protruded beyond the teeth. The rest of the body is stiff, almost tetanic, except that spasms cannot be excited reflexly. The mind is clear, the speech indistinct, the pain on swallowing less, he can take milk, eggs and beef-tea plentifully. The temperature towards evening reached 102.2°F. For a considerable time the extremities were almost free, especially the fingers could be moved fairly quickly; then the movements became spasmodic and exclusively painful; during the day the breathing was regular, although very much quickened (between 40 and 50). The respiration

that secretion of mucus on both sides of the throat, the patient can only expectorate with difficulty, for every effort to cough causes great pain.

20th.—Patient fairly well; much sputum; complained of pain in the head and breast; heavy perspiration; the whole body covered with sudamina. Tracheal rales continue; the breathing is quickened. In the morning Ext. Opil given subcutaneously, after which the pain decreased. Expectoration of sputum tranquil to-day. In the evening more opium, after which sleep came on, which lasted all night. At every attempt to expectorate a spasm of the muscles of the chest and upper extremities occurs.

21st.—Last night the patient was fairly quiet and slept well. Breathing still noisy. During the day no aggravation of the muscular spasms. The mouth can be opened better and the tongue protruded a little. Swallowing is not painful. No opisthotonos. The upper extremities can be moved. The hand can be carried sideways to the mouth.

The leg, which until now lay in a state of tonic spasm, admits of some active movement at the knee. The desire for food is great. Milk, wine and soda water are taken in large quantities. There was one stool after two days' intermission. The secretion of urine is somewhat diminished and still contains albumen.

Continued Extract Opil. Temperature the last two days between 100.4° and 102.2°F.

Wound going on well; secretion healthy, dressed antiseptically.

3rd June.—Condition unchanged. Head still drawn back, extremities stiff. Breathing rapid, noisy, and moaning. Expectoration still brings on spasms. The movements of the hand are fairly free, but not those of the arm. The abdomen is tense, and there is severe pain at the pelvic origin of the chest muscles. Muscles of the face sometimes relaxed, but again the expression becomes characteristic. The mouth can be opened at most a finger's breadth. The tongue, which is still bitten, can be slightly protruded. There is no difficulty in swallowing, and a healthy inclination for fluid nourishment exists. Mind perfectly clear. He is cheerful and takes a greater interest in his surroundings.

Extract Opil by injection continued. The limbs were, on the whole, more relaxed, and the tonic spasms have ceased. After the opium he passes a quiet night. Diffuse rales in the lungs.

Pulse quick. Heart cannot be auscultated on account of the moaning respiration. The wound has granulated. Motions sometimes passed spontaneously; sometimes after an enema. The quantity of urine cannot be accurately measured, as he sometimes passes it in bed.

6th June.—The mouse that was inoculated with urine died eight days afterwards with typical tetanic spasms. Yesterday and to-day no improvement. To-day, before the injection of opium, the whole body again became stiff with symmetrical cramp of the muscles, not increased reflexly. The muscles of the legs, back and head are tense and stand out like those of a statue. Breathing still superficial. Moaning accompanied with rattling in the throat. Sputum is forced out constantly once or twice a minute. The bronchial phlegm only is difficult to expectorate.

Opisthotonos unchanged. There is still albumen in the urine.

10th.—Tonic spasm of the body as before; the spasm of the muscles of the face and chest is perhaps even more marked than at the beginning. Movements of the forearm freer. General condition improved. Half solid nourishment in small quantities. The continued use of opium diminishes the pain, which is otherwise very severe. Spasmodic respiration has ceased, but even yet at every effort to cough there is a slight spasm of the whole body. The respiration is certainly easier; its rate has diminished from 50 to 25, and is no longer accompanied by head tilts. Natural stools daily.

17th.—No important change. Baths were tried once, but the result was unsatisfactory. Spasm of the muscles as before. The wound is going on well, but it discharges a dark green pus. Communication with the knee joint still exists. No pus in the joint.

20th.—The last two days towards noon the temperature rose, with great pain in the affected knee. A large amount of secretion is discharged from the opening in the joint, but there is no swelling. The cough is less. Stiffness of the neck has disappeared, but the stiffness of the back remains unchanged. The arm can be moved horizontally and the leg partly bent. Injection of opium, as before, is necessary on account of the great pain.

24th.—Since yesterday the fever has fallen, but there is still free discharge and pain in the knee. The mouth can now be opened a thumb's breadth and the tongue can be readily protruded. The back continues stiff. Movements of the extremities are still stiff and awkward.

Condition on discharge, 5th August 1895. Local.—The wound over the knee is healed and covered with epidermis, except a piece the size of a penny piece. The opening into the joint on the inner side of the patella is also closed and skinned over. The newly-formed skin is already fairly moveable. There remains slight effusion in the joint. The patient will soon be able to straighten his leg; it can be bent to a slight angle without pain. He can walk with a limp in the left leg, and is somewhat stiff and awkward in this side.

His body, when standing, is bent forward and the head is held stiffly. The expression of the face recalls the rictus sardonius. The reflexes are exaggerated. The mouth can be opened widely and the eyes moved without trouble. The contraction of the muscles is feeble. The lungs are normal and the urine also normal.

That we are justified in classing this case amongst the most severe is proved in the first place by the suddenness of the onset and secondly by the complex symptoms. For spasm of the respiration as severe as obtained in this case only appears in the worst forms of tetanus, and it is marvellous to note that the patient was not killed by it.

Since the opium treatment succeeded in preserving the patient until the poison was eliminated from the body, this must be accepted as a striking example of the success of the symptomatic treatment.

Opium had no power to prevent the respiratory spasm, having no specific action in this direction, and when this

occurred, it is manifest that it was the artificial respiration that preserved life; yet there can be no doubt that the general sedative effect of opium helped materially to preserve the patient.

Another narcotic that is very frequently employed is chloral hydrate. ROSE especially recommends it in maximum doses, and immense quantities have been taken with benefit to the patient. As chloral is not easily taken by mouth, and especially in large doses has an unpleasant effect upon the mucous membrane, it is best administered in the form of an enema with mucilage.

Again, it must be mentioned, that some investigators as THOMPSON recommend bromide of potassium, or paraldehyde, also nicotine in the form of tobacco solution administered per rectum and also tobacco smoke. Cannabis indica has also found supporters. SAHLI recommends that the narcotic should be varied and the dose carefully suited to the individual.

From curare much has been expected, and it appears to be very suitable on account of its paralyzing effect upon the endorgans of the motor nerves; in certain cases it has been given even in large doses. Its effect, however, remains doubtful. Moreover, it is handicapped by the slow development of its characteristic effects, which only appear after rigors, increased frequency of pulse and respiration, muscular spasm, perspiration, and increased secretion of urine and tears; lastly, the preparation is unreliable, and to be dreaded. Moreover, VULPIAN has said that to treat tetanus with curare is to add a new danger to the disease.

Success has in some mild cases been obtained with physostigmin, the alkaloid of Calabar bean.

Anæsthesia, either temporary or permanent, must also be included in the therapeutic measures. The results are not altogether encouraging, and the conclusions drawn from them have, undoubtedly, often been enormous, for the prolonged sedative action of the narcotics persisting after the anæsthesia have been looked upon as a direct influence upon the tetanic spasms, but after the effect has passed off the spasms have become more pronounced than before. Yet anæsthesia will sometimes be of use; for experience has shown that it has such an effect upon severe spasms of the respiration, that the impending tracheotomy for which it has been given proved to be unnecessary.

After opium and chloral very good sedative results have been obtained by the external applications of moist heat. ROSE does not recommend baths, because they on account of the unavoidable disturbance, excite the patient and sometimes increase the strength of the disease. Enveloping in hot, damp cloth is said to be beneficial. The sedative effect of cold has also been tried, but cold baths of short duration must be avoided, since death has resulted from them, but hipbath results have been obtained from cold applied slowly and for a long time.

It is very important in tetanus that a sufficient amount of nourishment should be given to preserve the strength, if it cannot be taken on account of trismus or difficulty in swallowing, nutritive enemata must be given.

COMMENTS AND NEWS.

THE ROENTGEN RAY IN WARFARE.

THE *British Medical Journal* says—"Surgeon-Major W. C. BEVOR, M.S., Army Medical Staff, gave an address on this subject at a meeting of the Royal United Service Institution on 30th May. The chair was taken by the Director-General, and the paper was concerned especially with the employment of the Roentgen rays during the recent operations on the frontier of India. Surgeon-Major BEVOR observed that one of the greatest desiderata in the construction of all apparatus for military work was that every portion of the apparatus should be easy of access, so that repairs could be made, while at the same time the whole could be quickly packed and unpacked in cases suitable for transport under the very rough conditions of actual warfare in mountainous countries. It appears that the apparatus used during the frontier expedition consisted of a 10-inch spark coil, a primary battery, three tubes, a screen, and some Paget photographic plates. The lecturer showed a compact and portable wooden box, into which a serviceable folding tube holder and a screen could be packed. He showed also a vulcanite box with a handle to take a Crookes's tube, to which insulated electrodes could be attached. This could be freely moved about and placed in any position necessary for the examination of the patient with the screen. Surgeon-Major BEVOR contended that it was the duty of every civilised nation to supply apparatus for the Roentgen rays not only at base hospitals, but also at every point where soldiers were fighting and exposing themselves to injury in the performance of their hazardous duties. The portable apparatus should not weigh more than 80 to 100 lbs., and could then be carried along from a pole by two men. Transport by mules, camels, or wheeled vehicles was too uncertain a means of conveyance for delicate apparatus except where there were good roads. A difficulty which had been met with was that a hot sun might melt the wax which insulated the wire of the secondary coil. It was found that a mixture of paraffin wax and resin which did not melt under 150°F. was enough for all practical purposes, while a covering of felt protected the coil from sun, rain, snow and frost. The screen, which was a most important part of the apparatus for urgent cases, could be enclosed in an aluminium case and protected from accidental scratches by a layer of celanite, as suggested by Mr. LACOSTEUX, of the London Photographic Association. Surgeon-Major BEVOR's paper was a valuable contribution towards the practical working out of the best apparatus for use in emergencies in the field, and those who have had experience of the difficulties which arise even in the best-appointed laboratories will be able to form an opinion as to the serious character of the obstacles likely to be encountered under limited conditions."

MR. ANRITA LALL BHATTACHARYA, I. M. S. ON THE SYMPTOMS OF PLAGUE.

THE presence of plague in the country is a matter of such great interest to the whole community, that it is not to be wondered at that a large number of communications on the subject appear from time to time in the daily press. Many of these emanate from persons who have absolutely no great knowledge of this, or any other branch of medicine, who are anxious to air some particular fad of their own and eager to court the small notoriety of appearing in print.

With these we have nothing to do, beyond expressing our surprise and regret that leading papers should give publicity to opinions which can do no possible good, and may do endless harm.

It is difficult, however, when we find a gentleman, an L. R. S. who is himself a practicing physician, exposing his own ignorance, while endeavoring to detect the mistakes of some one else. We consider it our duty to expose some of this kind lest many people may be misled by the erroneous doctrines made public by a qualified medical man.

In the *Englishman* of the 10th June a long letter appeared headed "Symptoms of Plague" and signed by the medical man whose name is given above.

In this letter the following sentence appears:—"Now a few words regarding the bacilli. If the malaria bacilli be identified with the plague bacilli, then the inoculation with plague serum, or, in other words, the introduction of the bacilli into the system as a safeguard or protection from an attack of plague, seems to be the most unreasonable measure that could be adopted." This sentence, short as it is, contains no less than two fundamental errors.

It may surprise Mr. BHUTACHARYA to be told that there is no such thing as a bacillus of malaria,—yet such is the case.

The micro-organism which is supposed to be the cause of malaria is not a bacillus at all, and no one, with the least possible knowledge of what he was talking about, could suggest the possibility of its being mistaken for the bacillus of plague.

To talk of "LAVREAN'S malaria bacilli" is totally wrong; LAVREAN'S body is an animal parasite commonly called the plasmodium malarie, all bacilli, on the other hand, belong to the vegetable kingdom.

The second error to which we allude is the suggestion that inoculation against plague may produce the disease, by the introduction of the bacilli into the system, this is calculated to discredit Mr. HAFKINE'S method of prophylaxis.

This suggestion is without foundation, for M. HAFKINE'S prophylactic serum contains no living bacilli, they are all carefully destroyed by heat.

M. HAFKINE'S method of preparing his serum was described in this journal of 16th December 1897, and therein it will be found that he says —

"The microbes in this fluid are killed by heat at 70°C maintained for one hour."

CHANGES IN THE NEW BRITISH PHARMACOPOEIA.

We quote from the *Chemist and Druggist* :—

Aqua Chloroformi is half 1885 strength, so that there is no longer need of diluting it with plain water when prescribing.

Ext. Belladonnae Alcoholic.—About a quarter the strength of the 1885 extract, owing to dilution with milk-sugar. Dose, now, $\frac{1}{2}$ gr. to 1 gr.; formerly, $\frac{1}{4}$ gr. to $\frac{1}{2}$ gr.

Ext. Nucis Vom.—Two-thirds the 1885 strength, but the dose remains the same.

Ext. Opil Liquid.—Formerly contained 1 oz. solid extract in 1 pint; now contained $\frac{1}{2}$ oz. Dose also less—viz., 5 to 30 minims.

Ext. Physostigmatis.—Owing to dilution with milk-sugar this extract is one-fourth 1885 strength, and the dose four times greater—viz., $\frac{1}{4}$ gr. to 1 gr.

Inf. Apomorphin Hypoderm.—Now 1 gr. in 110 minims, instead of 1 gr. in 50 minims as formerly.

Inf. Morphine Hypoderm.—Contains slightly less than half the morphine of the 1885 injection; now 1 gr. in 32 minims. Dose, 2 to 5 minims.

Liquor Xyliparatus is twice the strength of the 1885 article.

Suppositoria Morphine.—Each contains $\frac{1}{2}$ gr. of the aurate instead of $\frac{1}{4}$ gr.

Inf. Phosphoric.—A new one containing "1 in 30, instead of 1 in 50. Dose, 1 to 2 gr.

Tr. Aconite.—One in 30, instead of 1 in 5, but same dose.

Tr. Aurastii.—Fresh peel only used.

Tr. Belladonnae is no longer a tincture of the leaves, but of the root (1 in 15, formerly 1 in 30), and is at least twice, but probably three times, the alkaloidal strength of the 1885 tincture. Dose the same.

Tr. Chloroform, et Morph. Co.—Contains four times more morphine than *tr. chloroform. et morph.*, 1885, and has a larger dose—viz., 5 to 15 minims, instead of 5 to 10. Pharmacologically it is a totally different preparation.

Tr. Colchici Sem.—Now 1 in 5 instead of 1 in 8, and dose halved—now 5 to 15 minims.

Tr. Lobelia Elixiora.—Ditto.

Tr. Nucis Vomicae is double 1885 strength, and made from liquid extract.

Tr. Podophylli.—Almost double 1885 strength. Dose, 5 to 15 minims instead of 15 minims to 1 $\frac{1}{2}$ dr.

Tr. Strophanthi.—A very deceptive change. Now 1 in 40, instead of 1 in 20, but as 70 per cent. alcohol (which is a much better solvent than S.V.R.) is used as a menstruum instead of rectified spirit, the alkaloidal strength will be almost the same (say, $\frac{1}{2}$ to $\frac{1}{4}$ as the 1880 tincture. The dose is 5 to 15 minims, instead of 2 to 10.

Ung. Aconitinae.—Now 1 of crystallized aconitine in 50 instead of 1 of amorphous aconitine in 60; therefore at least three times stronger than the old ointment.

A COURAGEOUS GYNÆCOLOGIST.

WE frequently have to record, says the *British Medical Journal*, deeds of valour by medical men in the public services. Those deeds shed lustre on the profession, but at the same time, in the case of men who are in the strictest sense soldiers, they must be regarded as "all in the day's work," for it is the business of a soldier to be brave. Civilian practitioners, though they are more exposed to dangers than most other classes of the community, are seldom called upon to show the courage of the warrior. It is therefore with pride as well as pleasure that we quote from the *Daily News* the following account of the heroic conduct of Professor PORRO during the recent riots in Milan—"The mob," says the correspondent of our contemporary, "did not even respect the hospitals, but wished to invade them, and the Ospedale Maggiore was particularly threatened. Behind the gate of that building stood Professor PORRO, a Senator, a well-known doctor, and the most noted Conservative in Milan. The crowd were quick to see him. 'There is PORRO, our oppressor,' they cried threateningly, and insults were shouted at the Professor, who now, pale but calm, resolutely opened the gates, and stood with his arms folded, saying sternly: 'Let him, who has the courage, advance. He will find a good revolver ready for him. I will show how a good physician does his duty.' No one accepted the invitation." The incident illustrates the power which a determined man often exerts over an angry mob. Professor PORRO, with his revolver, recalls the sentry at Marlborough House when the mob of the "unemployed" streamed along Pall Mall with threats of pillage after one of the disorderly meetings in Trafalgar Square some years ago. The sentry in a business-like way prepared to use his rifle, and the crowd showed its appreciation of the maxim that the better part of valour is discretion. Professor PORRO's name is writ large in the history of modern gynæcology, and we have no doubt that if the hospital had been attacked, he would have used his revolver as effectively as he wields the knife. We congratulate him in the name of the profession of this country on his splendid devotion to the interests of his patients and his hospital."

ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

ANNUAL MEETING.

THE annual meeting of the Royal College of Surgeons in Ireland was held on Saturday, 6th June, Sir WILLIAM THOMSON, President, in the chair. The report showed an increase of income amounting to £548 7s. 3d.; 16 Fellows, 20 Licentiates in Surgery under the Conjoint Scheme, 9 Licentiates in Dental Surgery, and 3 Diplomates in Public Health were admitted during the year; 13 Fellows and 47 Licentiates died during the same period. The last instalment of the debt due by the general fund under the amalgamation scheme having been paid off, the Professors have again assumed control of the school teachers. A new theatre for the teaching of experimental and natural science has been constructed and fitted. The report was adopted.

ELECTION OF PRESIDENT, VICE-PRESIDENT AND COUNCIL.

On Monday, 8th June, the election of the new officers was held in the College. The outgoing President, Sir WILLIAM THOMSON, was succeeded by Mr. ROBERT LAFAYETTE SWAN, the Vice-President, and Surgeon to Stevens' Hospital.

For the vice-presidency there were two candidates, Dr. BALL, Regius Professor of Surgery in the University of Dublin, and Dr. MYLES, Surgeon to the Richmond Hospital. The contest has been in progress for many months, and it was generally believed that the Irish would be very close. Naturally the keenest interest prevailed; 267 Fellows voted, and after allowing for spoiled votes the poll closed as follows: MYLES, 183; BALL, 127. On the Council there were three vacancies, and one member (Mr. MURRAY) lost his seat. The new members are Messrs. OSOLY, CHANCE, CRANNY, and SHERLOCK. The following is a full list of the officers elected:—

President ROBERT LAFAYETTE SWAN, **Vice-President** THOMAS MYLES. **Secretary**: Sir CHARLES A. CAMERON. **Council**: ARCHIBALD H. JAGGER, EDWARD HALLAHAN BENNETT, HENRY GRAY CRODY, Sir PHILIP CRAWFORD SMYLY, Sir WILLIAM STOKES, HENRY ROSEBOROUGH SWANZY, WILLIAM IRELAND WHELAN, Sir WILLIAM THOMSON, AUSTIN MILDON, Sir CHARLES A. CAMERON, L. HEPENSTAL-CRANBY, RICHARD D. PURSEY, JOHN J. CRANNY, HENRY GREGG SHERLOCK, HENRY FITZGERIBSON, ARTHUR HENRY BENSON, FRANCIS T. HEUSTON, JOHN LENTAIGNE, and ARTHUR CHANCE.

NEW CANDIDATES.

For the next vice-presidency (1900) two candidates have already declared themselves—Mr. FRANCIS T. HEUSTON, Surgeon to the Adelaide Hospital; Mr. L. HEPENSTAL-CRANBY, Surgeon to the Meath Hospital.

SIXTY-SIXTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE sixty-sixth annual meeting of the British Medical Association will be held at Edinburgh, on Tuesday, Wednesday, Thursday, and Friday, July 26th, 27th, 28th, 29th, 1896.

President: T. G. BODDICK, M.D., Professor of Surgery in McGill University, Montreal.

President-Elect: Sir THOMAS GRAINGER STEWART, M.D., LL.D., F.R.S.E., Professor of Practice of Medicine and Clinical Medicine in the University of Edinburgh; Physician in Ordinary to Her Majesty the Queen for Scotland, Edinburgh.

SECTION OF TROPICAL DISEASES.

President: PATRICK MANNON, M.D. **Vice-Presidents**: ANDREW DAVIDSON, M.D.; ANDREW SMART, M.D., LL.D.; WILLIAM JOHN RITCHIE SIMPSON, M.D. **Honorary Secretaries**: JAMES GANTLIE, M.R.C.S., 48, Devonshire Street, Portland Place, W.; Surgeon-Captain M. LOUIS HUGHES, A.M.S., Aldershot.

The following *Discussions of Indian Interest* have been arranged: 1. The Undersided Empire of the Empire. To be opened by Brigade-Surgeon-Major-General COLMAN, F.R.S.

2. East-Feet in Temperate Climates. To be opened by COLONEL NORMAN, M.D. (Dublin).

3. The Epidemic of Plague in India. To be opened by W. J. M. SIMPSON, M.D. (Late of Calcutta).

The following among others intend to take part in the discussions or to send papers: Surgeon-Major-General HAMILTON, Inspector-General TURNBULL, R.N.; Dr. PATRICK MANNON, Professor HAPFORTH, Mr. HANSEN, Surgeon-Major ANDREW DUNCAN, Surgeon-Major RONALD BROS, Surgeon-Captain HUGHES, Surgeon-Captain SYMOND, Dr. ANDREW DAVIDSON, Dr. DANIELS, Dr. SANWITH, Dr. SANBORN, Mr. JAMES GANTLIE, &c.

THE COMMUNICATION OF SYPHILIS A CRIME.

THE *Philadelphia Medical Journal* has the following:—

"We hope that the bill now under consideration by the German Reichstag making the communication of a venereal disease to others by one so affected a crime punishable with fine and imprisonment, will be passed, and, if so, it will be a long step in sanitary and sociological progress which other countries should follow.

"We are convinced that an active educational crusade by the medical profession would place us in as advanced a position as Germany in a short time. Let it be known how large proportion of the population is tainted, how easily the virus is disseminated, and how much worse than fatal are many of the sequelae of these diseases, and an aroused public sentiment would compel the passage of stringent laws to limit their spread. Except by showing the public the danger that increasingly threatens, there is no hope of changing the status quo. A large proportion of the better class of unmarried women is totally ignorant that such evils as venereal diseases exist. The words syphilis and gonorrhoea would have as much significance to them as anterior poliomyelitis. And even the man about town is sometimes so unacquainted with the physical signs of syphilitic disease as to give himself away to his more 'knowing' brother.

"Were it not for the ethical and social complication of these diseases, no physician would oppose the report of such cases and passage of some law similar to that proposed by the Germans.

"And what we hold is that the principles which have inspired the legal measures for the restriction and suppression of other contagious diseases are applicable to venereal disease, and that it is the duty of the profession both directly, through recommendations to legislative bodies, and indirectly, through a proper enlightenment of the community, to do what it can to check this rot of western civilization."

NEW RULES OF THE ENGLISH CONJOINT BOARD.

Two important changes in the curriculum required for the diploma of the English Conjoint Board have been approved by the College of Physicians, and now only await the approval of the Royal College of Surgeons.

At the present time three examinations are required,—the first in Chemistry, Physics, and Biology; the second in Anatomy and Physiology; and the third in Medicine, Surgery, and Midwifery.

For the first examination a student is required to have passed one of the usual entrance tests in general education, and that he should show certificates of instruction in the subject of the examination. Certificates may be obtained at a large number of teaching institutions besides the medical schools. *Hispanic* is the rule not to admit a student to the final examination until five years from the date

of the examination, the medical student must, in about the time of his leaving a medical school.

The time taken the first year in a student's course can be spent on the study of Chemistry, Physics, and Biology at any place of learning, which are the medical, but which have been approved of by the two Colleges.

A student may now pass his preliminary a year before he leaves school, during his last year he will attend science classes in the same school; he can then go up for his first examination, and four years from the date of passing he will be allowed to go up for his final.

Thus his medical course after joining a medical school will be reduced to four years instead of five.

The second change sanctioned is also important, hitherto the rule has been that two years must elapse between the second examination and the final, and six months between the first and second. It is now proposed that the interval between the first and second should be one year instead of six months.

A MEDICAL SPEECH ON ALCOHOL.

MR. FRASER GOULD, says *The Lancet*, has been making a speech to the National Temperance League on alcohol and the advantages of doing without it, both in health and in the treatment of disease. It takes a strong man to say the strong things which Mr. GOULD said on the subject, especially if he happens to be a medical man. No doubt, as Mr. GOULD says, the use of alcohol in medical practice is nothing now compared to what it was twenty years ago, much more forty years ago, when Dr. TODD's influence and the reaction from the so-called antiphiolistic treatment were at their height. Public opinion has been enlightened by the evidence of leaders in medicine, such as Dr. PARKES, Sir WILLIAM GULL, Dr. GAIRDNER, Dr. SANDERSON, and others, and medical men have dared to treat disease without alcohol or with only small quantities of it. There are physicians and surgeons of reputation and success who are so strong in their convictions that alcohol is of little use in the treatment of disease, that it destroys tissues, lessens the resistance to microbes, deranges functions, spoils temper, and shortens life, that they are ready to testify to this effect in public in company with redoubtable champions of the temperance cause like the Archbishop of Canterbury, Sir WILLIAM WILKS (Chief Constructor of the Navy), and the Bishop of Derry, who have as much prejudice to contend against in their spheres as the medical man has in his. We recognise with pleasure the good done by such testimony as Mr. GOULD'S. Men whose record and authority in the profession are such as his have the courage of their opinions and their honest testimony will be respected even by those who do not go quite so far in discarding alcohol as an element of diet or as a medicine. On one point the profession is unanimous—that moderation in the use of alcohol must be observed unless certain mischief is to follow; the quantities which our forefathers regarded as moderate would now be thought capable of doing much harm.

THE MEDICAL WORK IN THE FRONTIER CAMPAIGN.

THE *Green Howard's Gazette* (the journal of the 19th Prince of Wales's Own Regiment) published at Gibraltar, writes as follows:—

"Our campaigning ended for the present with our return from the Banar Valley. If there is anything more to be said about it, I think it is a word of praise for our medical staff and our stretcher-bearers. The latter duty has been performed throughout the campaign by our bandmen and drummers under Sergeant-Drummer BAXTER and Band-Sergeant GIBSON, under the orders of Surgeon-Captain ALEXANDER, assisted by Assistant Surgeon KERR. We saw them all a

heavy load of patients, and their medical under very trying circumstances and in constant danger has excited universal admiration. It is not very genial work. Almost entirely unarmed, and with none of the excitement of fighting they have always had to go wherever the fighting was hottest, and generally to stay there and dress wounds before they could get their wounded out of life; and in setting again they have had no chance of nipping quickly over exposed places, as the ordinary fighting men do, because they have been encumbered by their—often dead—burdens. Even when they are not in danger, it is no joke to have to carry a dead or wounded man in a stretcher on a long stretch over steep and rough mountain tracks, as they have often had to do. Fortune favors the brave. Though these men have been more under fire, and in greater and more constant danger than any other men in the regiment, there is not a man of them who has not come back absolutely without a scratch, although we have had no less than forty-three killed and wounded in the rest of the regiment. All honor to them!"

LUNATIC ASYLUMS IN THE GENERAL PROVINCES.

IN the Resolution by the Chief Commissioner, on the Reports of the Nagpore and Jubbulpore Lunatic Asylums for the year 1897, it is stated that the total population of the two asylums in the year under notice was 882, of whom 203 were detained at Nagpore and 177 in the asylum at Jubbulpore. The past four years have been marked by a steady and satisfactory increase in the percentage cured, which is partly due to the system now adopted of transferring criminal lunatics on recovery to a Central Jail. Of the 68 admissions during the year the causes of insanity are reported as unknown in 81 cases. Of the 81 cases in which the cause of insanity has been ascertained, four are assigned to moral and 27 to physical causes. Among the latter are ten cases admitted into the Jubbulpore Asylum ascribed to privation, and in most of these the recovery, both mental and physical, has been rapid. No such cases are reported from Nagpore. In eight cases the cause of insanity is believed to be the use of ganja. Both asylums were less healthy than in the previous year. The management of both asylums continued good throughout the year, and reflects great credit on both the Superintendents. In Nagpore the dairy has continued to give excellent results, both financially and in regard to the health of the inmates, and Surgeon-Major HARRIS is congratulated on the results.

ENGLISH IN PRESCRIPTION-WRITING.

SAYS the *Philadelphia Medical Journal*:—"We think it time that Latin should not be used any longer in writing prescriptions. There is not one in a hundred physicians who can write Latin correctly, and a prescription that is one-half or one-fourth in Latin and the rest in English is barbarously ridiculous. We all hide our philologic ignorance under contractions that lead to ambiguity and even danger, and when we can no longer hold out with our wretched sham we are compelled to plunge into English for the directions. All arguments for this medieval nonsense do not amount to a pinch of snuff. As for hiding the knowledge of the drug from the patient, and the advantage to patients travelling abroad, the facts need only to be looked squarely in the face, and the argument for Latin becomes a bad humbug. The practice is a pompous bit of hypocrisy which should be left to medievalists and not scientists. As soon as we get our prescriptions out into the daylight of common sense and genuine science, we shall surely dispense with the sorry jumble of bad Latin and poor English illustrated by nine-tenths of the actual prescriptions on file to-day at the drug-store."

GOVERNMENT DOCTORS AND PRIVATE PRACTICE.

Indian Medical Pioneer's Gazette, referring to the Association's student representation to Government, says:—

"We heartily endorse the views expressed in the Indian Medical Association's letter. There is one point which we, as lay men, and having no understanding of these matters, should be glad to see the I. M. A. take up the cudgels about, and that is the following—Why, if the State-paid doctors are to be permitted to indulge in private practice, other than of a consultative nature, some protection should not be afforded by the State to these State-paid doctors' other employers—the public. Why, that is to say, should a State paid doctor not be liable to be banished over the coals should he refuse to attend a patient who is not a Government servant, one of the class who employ him in what, we consider, is his illegitimate sphere? Did a private practitioner refuse to turn out to visit a patient in an emergency—as some of these State-paid and public-paid doctors have, times out of number refused to do—he would be a marked man and he would undoubtedly find himself in the unfortunate position of OTHELLO before very long. The State-paid doctors, we are aware, take fees from the public as a favor and attend them in the same spirit, if they refuse to turn out in an emergency to attend one of their private patients they are none the worse off, for even if they lose their private practice, so long as they perform their duties to the State, they have always their State pay to fall back upon. If the Government of India turn a deaf ear to the letter of the Indian Medical Association—this we think should be the next question for the Association to put."

HAFKINE'S PLAGUE SERUM DOUBTFUL.

THE inoculations with Dr. HAFKINE'S plague prophylactic performed on Mr. LEE and Dr. ALLES at Colombo on Saturday, 28th ultimo, have, says the *Ceylon Times*, proved unsuccessful. A representative of that paper, who saw Dr. PERRY, was informed that this was due, possibly to an insufficient quantity of the serum being injected. The serum, so far as they knew, was all right, and it is very likely that the first-named two officials will stand another inoculation. The serum can be kept for an indefinite period, provided it is not exposed to light, and the stock in Colombo was kept in the best order. Asked as to whether the serum which was used could possibly have been rendered ineffective, the supposition being that the plague bacilli could not exist in a latitude as low as Ceylon, the information was vouchsafed that that was not at all likely. The theory put forward by some that the plague bacilli could not exist in these latitudes required scientific support. It was only a matter of experience and could not stand scientific reasoning. Here there was everything favorable for bacilli to thrive—heat and damp, and given these, all bacilli would multiply and flourish.

COOKERY AS A BRANCH OF MEDICAL STUDY.

The Lancet says—"The medical faculty of the State University of Minnesota has decided to add a new course to the medical studies of that institution. As soon as the new term begins the senior class will have to take up the study of cooking. On the catalogue this study will be designated 'Practical Dietetics.' The students will have to go into the 'laboratory' and make soup, tams, gravies, farinas, and a host of other dishes for the sick and convalescent. Is the time coming when the overburdened medical student will be required to 'take up the study' of cutlery (to be designated 'Practical Scalpelography') because he may have occasion to use knives; of plumbing because it may fall to his lot to inspect drains; of bed-making, sweeping, and dusting that he may more efficiently direct the practice of these mysteries in the sick room; of hardware manufacture that he may be able to pass a sound judgment on the quality of his gallipots?"

THE PHILOSOPHY OF MEDICAL PRACTICE.

Superstition, intuition,
Universal imbibition,
Disappointment and reaction,
Then again sound observation,
Oh! naïf empiricism,
Diet rules and regulation,
Theories of chemist, analytical;
Puffs of cure-all, hypocritical;
Grateful touts of "perfect cures";
Wealthy, pampered epicures!
Science scoffing, Fashion smiling;
Yet the walls are still beguiling
Men and women for their healing—
Pare reason—proved by feeling!
"Powers of nature count still";
Atoms, cosmic force or veil!
So the cycle we fulfil,
And the fruit of eradication
Mystery—like superstition!

SUMMARY OF MEDICAL AND SURGICAL WORK PERFORMED IN GONDAL HOSPITAL DURING 1906.

DR. HARI BHICAJI, Chief Medical Officer, and his Assistant Dr. S. S. SHAH, L.M.S., send us the following—

1,156 in-door and 9,897 out-door patients were treated, 168 Major and 613 minor surgical operations were performed during the year. The following list gives the names of surgical major operations—

Removal of large tumours from parts	...	8
Removal of foreign bodies deeply situated and in the dangerous neighbourhood	...	4
Opening of large abscesses	...	27
Operations on the eye and its appendages	...	67
Plastic operations of the ear	...	2
Plastic operations of the nose	...	2
Lithotomies	...	4
Litholapaxies	...	4
External urethrotomies	...	4
Tenotomies	...	3
Paracentesis of the abdomen	...	12
Amputations	...	13
Reduction of dislocations	...	6
Forcible extension of flexion	...	2
Reparative operation of the scrotum	...	8
Operations for hæmorrhoids	...	4
Removal of diseased lymphatic glands	...	8

CAN COMPANIES CARRY ON MEDICAL PRACTICE?

The Lancet says—"It would seem incredible to the uninitiated that it should be possible for totally unqualified persons in the exercise of medical practice to be protected by the Companies Act. But such is the case. The subject was brought before the General Medical Council by a member *à camera*, who pointed out the valuable opportunity afforded by the occasion of the Companies Act Amendment Bill for providing a remedy for such a scandal. The Council afterwards gave leave for the motion on the subject passed *à camera* to be placed on the minutes. It is as follows.

"That the President, Mr. TOMES, and Mr. HORSLEY be a committee to take such steps as they deem most effective to induce the Government to insert a clause in the Companies Act Amendment Bill now before Parliament, with the object of preventing the registration of companies to carry on medical, surgical and dental practice."

"The General Medical Council will do good service if it succeeds in this matter."

RECOMMENDATIONS FOR M.D. EXAMINATIONS.

A CANDIDATE for the M. D. is required to show a good general acquaintance with medicine, theoretical and practical. The following books may be read or consulted, but there are others which would serve the purpose equally well: *FAGGE'S Principles and Practice of Medicine*, edited by Dr. F. A. SMITH (London: J. and A. CHURCHILL, 40s.); or *OSLER'S Principles and Practice of Medicine* (London: YOUNG J. FENTLAND, 34s.); *GREEN'S Pathology*, edited by MONTAGUE MURRAY (London: H. KENNEDY, 1895, 7s.); *SIMS WOODHEAD'S Practical Pathology* (London: YOUNG J. FENTLAND, 25s.); *GOVERN'S Manual of Diseases of the Nervous System* (London: J. and A. CHURCHILL, 1895); *WHITELLEGGE'S Hygiene and Public Health* (London: CASSELL and Co., 7s. 6d.). Reference should also be made to articles in CLIFFORD ALLBUTT'S *System of Medicine* (MACMILLAN and Co.). We cannot recommend any book on medical anatomy, but should advise "M.D." to read parts of QUAIN'S *Superficial Anatomy*, 10th edition, 1896 (LONGMANS, GREEN, and Co.), and to supplement this with reference to any standard book on anatomy.

A STRIKING INSTANCE OF MATERNAL IMPRESSION.

GARDINER (*Amer. Jour. of Obstet.*) gives an instance of maternal impression which is no less striking than it is well-authenticated. An American woman had, during her third pregnancy, an unbearable craving for sunfish. During the fourth month her husband brought home for her some of these fish alive in a pail. She stumbled against it on the porch, and one of the fish flopped over the edge of the pail and came in contact with her leg. It sent a cold chill through her, but the pregnancy was not disturbed, and nothing further was thought of the accident until the child was born, when, to her surprise, a nevus in shape and size closely resembling a fish was seen upon the leg of the baby in the part corresponding to that of her own leg with which the fish came in contact. Otherwise the child's health was perfect, and she lived to grow up into a healthy woman. The annoying craving for sunfish, which was temporarily present in her mother, existed in her throughout a long life. It much resembled a drug habit. Time and again she has eaten sunfish until from repletion she has vomited, and then again has eaten them with unabated appetite.

SPECIALISTS AND PRACTITIONERS.

THE *Journal of Eye, Ear and Throat Diseases* quotes from the *Archives internationales de laryngologie, d'otologie et de rhinologie* the following regulations that have been adopted by the Medical Society of the Ninth District of Vienna: 1. The specialist is a physician who renounces the exercise of every other branch, with the exception of a very limited portion. 2. The specialist should not undertake any treatment without coming to an understanding with the ordinary physician of the family. 3. The ordinary physician should be informed of the diagnosis and his advice taken upon important interventions. 4. It is impossible for the ordinary physician to direct the treatment to be followed; the specialist should let him take part according to his ability. 5. The patient should not be referred by the specialist to a third physician, except with the assent of the ordinary physician.

THE HYDERABAD CHLOROPHORM COMMISSION.

Dr. T. LEWIS BRUNTON, M.D., writes to the *British Medical Journal* as follows:—"Although Mr. HILL's letter in the *British Medical Journal* of 4th June, p. 1492, might lead a reader, who had not followed the controversy, to think that I had made an attack upon him instead of merely defending the work for which I was responsible, yet my only object

has been to defend his work against the attempt he made to destroy it. As he has completely failed in this attempt and now retires from the contest, leaving the trustworthiness of the experiments beyond question, my object is attained. The only pity is that Mr. HILL has not recognised until now that the introduction of a personal element into a controversy does not forward the ends of science. Had he done so before he brought his accusations against the work of the Hyderabad Commission, the whole of this controversy would have been avoided."

THE ANGLO-INDIAN CAUSE AT MUSSOORIE.

Dr. JOHN MORTON, M.D., Secretary to the Imperial Anglo-Indian Association at Mussoorie, writes as follows to the *Statesman*:—"In connection with the agitation over the Anglo-Indian Cause that is going on at Mussoorie, will you allow me to state, that the news that Dr. J. R. WALLACE has been unanimously chosen as the delegate of the Anglo-Indian Association of Calcutta, to represent that body at the forthcoming Conference of Delegates from all India, to be held, as now suggested, at Mussoorie, has been received with unqualified satisfaction. Dr. WALLACE has done yeoman's service for the cause of the Disfranchised European Community, and his presence at Mussoorie will unquestionably do a vast amount of good in advancing the inauguration of the Anglo-Indian Association at this delightful hill station. Dr. WALLACE, should he be able to come to us, is sure to have a most cordial reception."

A DEFINITION OF MEDICAL PRACTICE.

SAYS the *British Medical Journal*:—"JOHN HUNTER said that 'definitions are the most damnable things,' and certainly the definition is often by far the most troublesome part of a proposed legal enactment. A Kentucky judge has recently given a definition of medical practice which seems to be fairly satisfactory. In pronouncing sentence upon an 'osteopath' who was convicted of having subjected a child suffering from tuberculous disease of the hip-joint to cruel and unnecessary torture, he laid it down that 'any person, who for compensation professes to apply any science which relates to the prevention, cure, or alleviation of the diseases of the human body, is practising medicine within the meaning of the statute.' This concise definition is probably comprehensive enough to include every form of quackery."

THE SO-CALLED CALCUTTA PLAGUE.

WHAT the daily papers still style the "sporadic plague" continues to claim two or three daily victims. From the 16th April up to the 26th June, a whole *posse* of plague Doctors, Inspectors, and an army of Vigilance Committees, have managed to ferret out 148 cases of sorts, of which 106 have proved fatal. Meanwhile the death-rate of Calcutta stands at 88 *per mille* compared with 50 as the mortality of the previous five years. There have been 1,775 anti-plague inoculations (about 800 of these on purdah women). It would be extremely interesting to obtain a verified analysis of these plague cases together with a verified diagnosis in each. It would be still further interesting to analyse the death-rate from fever in the city during the past three months, and to compare such a statement with the fever mortality of the past five years during the months of April, May and June. We believe there are no less than 16 plague doctors employed in the city. Allowing that each of these officers has discovered an equal number of these so-called plague cases, we have on an average 9 cases per man in two and a half months or 4 cases per man per month. We pay each plague officer 500 rupees per mensem, therefore the discovery of each of these malignant fever cases costs the Municipality and the Calcutta tax-payer 125 rupees per head. Judging by the state of events during this unfortunated plague invasion, we might well ask the Bengal Government, the Plague Commission and all concerned in this unhappy fiasco, is the game worth the candle?

PLAGUE IN AFRICA AND INDIA.
 There is a special report of the plague from Africa, which states that the disease is spreading that it is the most serious threat to the continent. It is extremely rapid in its progress and is spreading with great rapidity. With such a rapid progress, the disease must be careful not to reach to extremes. It must be taken to enforce on the African population an experimental preventive, which, however promising, could not in the present state of our knowledge be rendered compulsory in any English city."

THE PLAGUE IN BOMBAY AND THE PUNJAB.

The plague continues in its deadly and virulent in Bombay and Karachi. In the former city there are now on an average about ten to twelve daily seizures with six to ten deaths. In the latter city the figures show about six to eight daily seizures with four or five deaths. In Karachi up to the present date (27th June) there have been 2,968 cases with 2,386 deaths. There are no cases reported from Lahore nor any from the Jullunder and Hoshiapur Districts of the Punjab, where the disease was epidemic a short while ago.

ROUND WORM CAUSING APPENDICITIS.

DURING a clinic in the surgical amphitheater of the University College of Medicine, Richmond, Va., held 8th January 1898, for Dr. HOWARD MCGUIRE, Dr. JOSEPH PRION, of Philadelphia, exhibited an appendix which he had removed from a patient the day before because of appendicitis. In the appendix was a full-sized round worm (ascaris lumbricoides) which had evidently been a cause of the appendicitis. This case was unique in his practice in that it was the only time he had ever found a worm in the appendix. He has, however, many times found all sorts of foreign bodies, as seed, etc., in the appendices he has removed.

A HANDSOME AMERICAN REQUEST.

MRS. J. C. AYER, relict of Dr. AYER of patent medicine fame, has left \$80,000 to the University of Pennsylvania. Related to the CLAPLINS of dry-good name and a Yankee by birth and ancestry. She married Dr. AYER when he was only a drug clerk in Lowell; but though she developed very expensive tastes and extravagant habits, business prospered so well that at her husband's decease she became the possessor of \$15,000,000 dollars which she transferred with herself to Paris where for several years she spent her great income right royally in leading society and gratifying her tastes and love of display. She leaves three children who reside in New York City.

PUBLIC ANTI-PLAGUE MEETING IN CALCUTTA.

An influentially initiated requisition is in course of signature, calling upon the Sheriff of Calcutta to convene a public meeting on an early date at the Town Hall, at which the present health of the city and its sanitation will be discussed. The requisition urges that the time has come when independent professional and unbiassed opinion should be associated with the Government and Municipal Medical Officers in diagnosing and deciding the nature of what are styled suspected plague cases.

A DEFERRED STUDENT.

In Vienna, recently, a medical student, not 70, died just before his final examination; while another who has just graduated in Warsaw in his 75th year of life, commenced his course in 1848, but was obliged to suspend it from lack of funds for nearly 30 years, and had barely returned and resumed his course of study when he was deported as a political prisoner to Siberia salt mines, where he stayed from 1883 to 1895, when he obtained a pardon and returned to Warsaw to graduate at last.

AN AMBULANCE SHIP.

The United States ambulance ship *Albatross* is not a hospital ship, but, as the name implies, a place for the temporary treatment of the wounded. She carries powerful steam launches and barges for transferring to a dock and wounded at sea. She has a completely fitted up operating room; dispensary, operating room and disinfecting chamber; there are state-rooms for wounded officers and quarters for injured seamen. There are 4 medical officers, 8 apothecaries, 6 trained nurses, 2 laundrymen, a cook, and 4 men-attendants attached to the medical department of the ship.

It may interest some of our readers to know that the army to which the 10th Division was sent, and which was sent to the front, have secured the medical officers now in command.

A house in the cantonment, near the 10th Division, was struck by lightning and burned down. No one was hurt, and the contents were saved. The artillery and E. O. S. Division were sent on the spot with their fire-engines, and the house was bed-ridden for the past six months, and the house was kindly taken in by Surgeon-General P. M. O. S. Division.

Clarke records a case of Ovarian cancer in a woman of 40 and hand presentation complicated by foetal prolapse. The uterus was in a state of tonic contraction; the fetus was dead and impacted; and there was great vaginal callosities. Evacuation was practically impossible. Uninterrupted recovery followed the operation. The patient was married and of full size.

At the Whitechapel County Court on 2nd June, before his Honor Judge Bacon, Leopold Liebler, M.D. Vienna, was sued by the Society of Apothecaries for practicing as a apothecary without the necessary diploma. Judgment was given against the defendant for the full amount claimed—£20 and costs.

Lord Playfair, who has just died, was the son of Deputy Surgeon-General George Playfair of Bengal. He was born in Meerut and was partly educated in India. His brother, Dr. W. S. Playfair, Professor of Obstetrics in King's College, London, was also born in this country.

Johnston prescribes magnesium sulphate 2 drachms, with aromatic sulphuric acid, 5 minims every 4 hours, until plenty of bile appears in the stools. He then gives orange juice in water. Dysentery is said to disappear in two or three days under this treatment.

At one of the large dispensaries having special department an applicant recently took tickets for each class, and spent the day obtaining expert opinions on the condition of his eyes, nose, throat, internal organs, and skin, and it is said even had a little surgery done and got a tooth pulled.

Quarantine, if continued for considerable periods of time, is safer with carefully regulated communication than under the rigid non-intercourse rule. This should be permitted under rules having for their object the greatest safety to other communities and the least inconvenience.

Surgeon-Colonel Townsend, P. M. O. S. Khyber Force, having proceeded to assume charge of the Sindh District, Brigade-Surgeon Lieutenant-Colonel Blood, from that district, replaces him in charge of the Khyber Brigade.

Mr. A. J. Hughes having gone home, the duties of the Conservancy Department of this city will now be supervised by Dr. Cook, the Health Officer. The Government does not intend to supersede Dr. Cook in his work as a plague officer.

The case of congenital goiter in a nursing, by thyroid medication taken by the mother, is reported by Home. The child showed the effects of the treatment more promptly than the mother.

Surgeon-Captain J. G. Jordan is appointed to act as Deputy Sanitary Commissioner, Metropolitan and Western Bengal Circle, and to be an Assistant Health Officer of the Port of Calcutta, in addition to his own duties.

Surgeon-Captain J. C. S. Vanden is re-appointed to be Deputy Sanitary Commissioner, Western Bengal Circle, and is also placed on special duty in connection with anti-choleera inoculation.

Surgeon-Captain W. J. Buchanan acts as Superintendent, Central Jail, Dacca, in the room of Mr. W. A. D. Jordan, who goes on three months' leave from the 15th proximo.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

Surgeon-General Sir J. G. Macdonald, G.C.B., D.S.O., has been appointed **Honorary Physician to the Queen**, vice Surgeon-General S. Currie, deceased.

COMA

Dr. J. T. Barnard, of Denver, in an article in the *New York Medical Journal*, entitled "Delineating the Causes of Coma," says:—

"The proper management of cases of coma depends to largely upon our knowledge of the cause of the coma. It is necessary for us to have a comprehensive knowledge of the various symptoms of the coma that results from each of the numerous causes.

Coma may be gradual or sudden in its onset—complete or incomplete. Stupor or partial insensibility has been used to designate incomplete coma.

Coma either than that caused by hyperpyrexia, typhoid fever or cancer in parts of the body other than the brain, the author divides for the sake of convenience into the following seven groups:

1. Transient coma.
2. Coma from lethal doses of medicinal agents.
3. Coma from poisons other than medicinal agents circulating in the blood.
4. Convulsive state from coma.
5. Voluntary coma.
6. Coma from profound disturbances of the cerebral circulation, but unattended by organic lesions of the brain substance.
7. Coma from organic disease of the brain.

Were it not that many of the above causes of coma are so infrequently factors in giving rise to unconsciousness, mistakes in diagnosis would be much more frequent than they really are. The major portion of the author's article is made up of a careful résumé of the symptoms belonging to the different groups into which he divides the comatose state and the causes thereof."

Experiences with Leprosy.

STICKER relates his experience in India and Egypt. He first discusses the pathogenesis of the disease. He states that (1) lepers eliminate with the nasal secretion the leprosy bacillus often in extraordinary numbers, and during the greatest period of the disease, and (2) the front part of the nasal mucous membrane, and mostly that covering the nasal septum, is the place which leprosy first, and perhaps always, attacks. The author has examined 143 lepers from this point of view. In 55 out of 57 cases of tubercular leprosy the leprosy bacillus was found in the nasal secretion, and yet in only 2 cases were there any leprosy nodules in the nose.

In 45 out of 58 cases of anesthetic leprosy, and in 27 out of 28 of the mixed form, the bacillus was also found. Only one examination was usually made, and not more than two or three cover glass preparations. In 25 out of 143 cases there was evidence of disease in the trachea, but in only 14 of these were leprosy bacilli found in the sputum. In 10 out of 27 cases in which the exudation from the nose was examined, the leprosy bacilli was found. In 21 cases the bacillus was demonstrated in the secretion of the fauces on 9 occasions. The author thus concludes that the nose is the chief place from which the leprosy bacillus is given up, and that in the nose the first effect of the leprosy bacillus is profound. In the exceptional cases where no bacilli was found, there were always present the most marked traces of a nasal lesion, which in an active state would produce secretion. The nasal lesions are varied. In the first stage the mucous membrane may look healthy, or at most there is slight increase of a silvery secretion. The first visible change is a slight dryness in circumscribed patches, which eventually present a raw surface. In advanced cases the raw areas are visible in one or both sides of the septum. Sometimes there is a hard swelling only, which may be extended to adjacent parts, and produce a nasal stenosis. Degeneration of the sputum, or even more destructive changes, may occur, so that the whole nose may be eaten away. The secretion is mucoid, purulent, or of a characteristic silvery character; the last named contains most bacilli.

The author gives a table showing the nature of the nasal lesion in his cases. Leprosy can spread from the nose to other parts by way of the lymphatics, or more rarely by the blood. In the tubercular form the lesions mostly affect the face and also of the nose, and even in the anæsthetic form early changes may be seen in the face. The author has found the leprosy bacilli in the blood in 4 cases. Finally, he draws attention to the importance of the nasal treatment, not only on account of the patient himself, but also in order to prevent the spread of the disease.—*Gaillard's Med. Jour.*

Prophylaxis of Nephritis in Scarlet Fever.

To prevent this dangerous complication Professor ALFARO advises:—(1) Promote diuresis by a milk diet with plenty of drinks and cold hydrotherapy (in severe cases), but (2) avoid elimination per kidneys of phenol, salicylic acid, antipyrin, and all other irritating substances, whether as medicines or as food. (3) Keep skinfunction active by general friction with fatty substances and tepid baths during desquamation. (4) Frequently employ mild antiseptic applications to keep the mouth, nose and pharynx aseptic; but (5) on no account use antipyrines or antiseptics that may injuriously affect the kidneys by absorption or elimination, and (6) above all avoid sudden or continued exposure to cold air.—*Anal del Cir. med. Argent.*

Auscultation of the Mouth.

As a means of diagnosing insipient tuberculosis, &c., is highly advocated by Professor GALVANI who shows the râles are reflected from the bucco-pharyngeal cavity as from a sounding board and a peculiar jerky glottic sound, which coincides with the rhythm of the pulse of tuberculous patients is noticed not in the inspiration, but commencing in the pause, attaining its height about the middle of expiration, diminishing and vanishing completely at the commencement of the inspiration. These sounds are not heard in the mouths of healthy persons.—*Gaz. degli Osp. e del Clin.*

Iodoform Injections in Tuberculous Lymph Glands.

HAMMERBONLAG has been remarkably successful with intra and peri-glandular injections even in the large-celled hyperplastic lymph glands on tuberculous subjects, which usually are sent to the surgeon. After local anaesthesia he injects 1 to 2 cc. of a 5 to 10 per cent iodoform glycerin emulsion first on one side and a week later on the other. He declares the results were remarkably quick and so satisfactory that the tumours subsided until not so much as a trace of them could be seen above the skin and no scars were left.—*Dent. Med. Week.*

Pseudopastic Parosis with Tremor.

DR. ORUY describes a case of the rare affection to which FURBERG gave the above name: A man, aged 40 years, a heavy drinker, was struck on the top of the head by the corner of a trap door. There was immediately paralysis of the face and all the limbs, with loss of sensation, but no loss of consciousness. No external injury could be found. After twenty minutes speech and facial movement were completely recovered; power was recovered more slowly in the arms and legs. After four months power was completely restored, but there were curious tingling sensations in the hands; the most striking and troublesome symptom remaining was the occurrence of a violent trembling and shivering of the whole body on the slightest excitement. The deep reflexes were greatly increased, and any attempt to elicit them caused shivering movements of the limbs; plantar and abdominal reflexes were absent. Gait was high stepping, of spastic type. The pathology of this affection is uncertain. Suggestions have been made that it is a functional disturbance or traumatic neurosis, that it is due to a traumatic lesion of the spinal cord, or that it is due to capillary hæmorrhages in the brain. None of these theories, however, will explain all the cases that have occurred.—*Pac. Med. Jour.*

SURGICAL.

Treatment of Spinal Curves by Entering the Spinous Processes.

HAVING chloroformed the patient and placed him upon his abdomen in three quarters pronation, A. GEIFAVLT runs an incision along the spinous processes extending over the borders of the curvature above and below by 2 or 3 vertebrae. The soft parts are drawn out of the way and the spinal processes laid freely bare without touching the inter-spinal ligaments. Reduction of the gibbus having been made, a silver wire is passed through the ligamentum spinale and cut off in such manner that a free end, twice as long as the incision, remains hanging on each side of the perforation. The spinal processes are sutured together by crossing these two wires and passing each of them separately through the ligamentum spinale immediately below it and then through each successive one until the lowest of the exposed spinal processes is reached when the ends of the wires are twisted together, after which the soft parts are drawn together without drainage, a bandage applied and the patient put to bed. The dressings may be changed and the sutures removed from the soft parts in 5 to 10. This operation is useless in cases of advanced deformity.—*La Med. Mod.*

Unusual Laryngeal Growth.

A RUSSIAN Jew, æt. 38, complained of hoarseness for a year, but had no cough, dyspnoea, emaciation, glandular enlargement or pain. From the anterior commissure to the arytenoid cartilage of right half of his larynx was occupied by a white, slightly corrugated mass with irregular edges looking all the while like a plug of cotton tucked into the ventricle, but which did not interfere with the laryngeal movements. Dr. J. W. GLEITSMANN, who excised about one-quarter of this mass in two sittings thinks it was a hard papilloma, probably malignant and possibly carcinomatous. There was papillary proliferation of the mucosa with a thickened epithelial covering, the outer portion of which was horny and the underlying epithelia were proliferated and the nuclei split up. A small-celled infiltration of the submucosa was noticed, and the epithelial layer showed a tendency to invade the subepithelial tissue, while the individual tubules or ducts of the marginal glands were so affected that the cylindrical epithelium merged from one duct into another.—*Amer. Med.-Surg. Bul.*

Intestinal Suture.

In enterotomy the abdominal wound should be partly closed with silkworm gut sutures which, being introduced at both ends of the wound, should include the peritoneum, bringing it as near the cut margin as possible, while the wall of the bowel should be stitched to the skin-margin, closely surrounding it, with fine silk-sutures which should involve skin and serous and muscular coats of bowel. After opening the gut silkworm sutures, transfixing the whole thickness of the intestinal wall, should be passed laterally from the skin toward the gut, to hold the latter in position and in closing abdominal wounds interrupted silk or silkworm gut sutures are best. The chief moles of applying sutures are:—CUSHING'S right-angled continuous suture, OBERNY'S, DUPUYTREN'S, GILLY'S, HALSTEAD'S, LEMBERT'S, and SMITH'S modification of JACOB'S method of applying suture in invaginating method of uniting free ends of the gut in resection; but of all these LEMBERT'S suture has stood the test of time, and may safely be recommended as the best form of suture.—*Pac. Med. Jour.*

Fractures of the Clavicle.

MAY be oblique, transverse or longitudinal, rarely comminuted, comminuted or broken in more than one place, and

with the exception of that of the middle fracture of the clavicle in which slight irregularities of any bone. To treat it Dr. CHAS. F. SPENCER, through the point where the depression is most marked and separating the wound edges little as the exposed fragments with a periosteal elevator which holds the skin in position while they are drilled for the reception of silver sutures. The periosteum is also sutured and the skin wound closed after which the arm is dressed in the VULPEAU dressing with a light plaster-of-Paris bandage. By this method Dr. SPENCER claims that the risk of injury to the artery and vein, the interruption of the muscle fibres which would delay union and injuries to the lungs are avoided, while the deformity resulting from this injury is considerably lessened by this method.—*Amer. Med. Jour. Science.*

Treatment of Snake-Bites.

THE *Press Medical* calls attention to the following method of treatment advocated by MR. FARRINGTON: 1. A ligature should be applied above and as near as possible to the wound. Sucking the wound should be practised if the integrity of the buccal mucous membrane of the person who does the sucking is assured. 2. The wound should be washed with a one-in-sixty fresh solution of calcium hypochlorite. In the wound and round it from eight to ten injections of a cubic centimetre each of the same solution should be practised. 3. The ligature should be removed. 4. If antivenomous serum can be easily procured, an injection of ten cubic centimetres should be administered as soon as possible, with the usual antiseptic precautions. Ordinarily this quantity suffices, but if the serpent belongs to a very dangerous species, or if medical intervention has been delayed, it is best to inject two or three doses simultaneously; in urgent cases intravenous injections should be practised in the bend of the arm. In adults the injection is still very efficacious an hour and a half after the subject has been bitten. 5. If threatening general symptoms are produced, a proper treatment should be instituted; for instance, the administration of caffeine or of ether, the injection of three twentieths of a grain of strychnine, general friction, inhalation of oxygen, and artificial respiration, and keeping the patient warm. 6. Antiseptic dressings should be applied to the wound.

If it is not possible to obtain these drugs, the calcium hypochlorite may be replaced by Javelle water, Labarraque's solution, or a one-per-cent. solution of potassium permanganate. If the antivenomous serum cannot be procured, subcutaneous injections of the calcium hypochlorite must be practised. The employment of large saline injections is also indicated.—*N. Y. Med. Jour.*

Case of Double Penis.

ENRICO GIOFFI records a case of a child born at Sala, Conslina, with double penis and atresia of the anus. The parents refuse operative interference. Each penis is well formed, with prepuce, glans, urethra and corpora cavernosa. To one penis is attached a testicle, to the other a simple scrotal fold and thence and urine are discharged from both apertures.—*Reforma Medica.*

Aspiration Treatment of Inguinal Bubo.

R. HARRIS reports 70 per cent. out of 300 cases cured by aspiration of the contents of the tube, requiring no further operation (75 per cent. with one single aspiration). The cavity is then lined with salt solution and a gauze pad applied, held with a zinc plaster and compressing bandage outside to reduce the distended skin and prevent the accumulation of more pus. If the discharging trunks are found to be inviolably established in continuity, but otherwise aspiration will be found sufficient.—*Sanitätsber. d. d. Armee.*

GESTATION AND GYNÉCOLOGY. Complete Inversion of the Uterus following A Bortion.

SWITALSKI records the case of a woman, *et. 36*, who had four normal labors—and aborted at fifth month, followed by excessive hemorrhage and inversion of the uterus. Attempts at reduction under anesthesia, after the methods of STANSON and HEMMET, failed, but had the effect of producing an extensive laceration in the anterior cervical wall. An opening was made into the pouch of DOUGLAS through the posterior fornix, when it was found that the entrance to the inverted depression was so narrow as scarcely to admit the point of the finger. An incision (after KUSCHKE) was made through the posterior uterine wall, commencing 3 cms. above the external os, and reaching to 3 cms. from the fundus, allowing the latter to be easily reinverted. The uterus was then brought into the vagina, through the opening into the posterior fornix, and the wound on the posterior wall sutured with subcutaneous catgut.

Microscopic examination of pieces of mucous membrane and muscular tissue, removed previous to sutured union, showed changes similar to what one would expect to find in a result of long-continued vascular and lymphatic engorgement.

SWITALSKI refers to two other cases, one following an abortion at the fifth month, the other at the fourth; in the latter the inversion occurred after the expulsion of the placenta three weeks after that of the fetus.

He suggests that before beginning manual reposition it is well to ascertain the condition of the cervical wall, as, on account of its thinness from muscular degeneration, it is apt to tear. Reference is made to the uncertainty and danger of Thomas' operative treatment of such cases, and SWITALSKI gives preference to FOLK's method of opening the vesico-uterine fold of peritoneum, incising the constricting ring at the entrance of the funnel-shaped depression, and then reinverting the uterus.—*Mün. Med. Jour.*

Management of the third stage of Labor.

PROFESSOR BYRNE read a paper on this subject. He said that there were two factors to be considered in the third stage of labor: (a) the separation and (b) the expulsion of the placenta and membranes, and it would be necessary to examine how nature herself managed this period. He then discussed the various theories put forward to account for the separation of the placenta—*viz.*, the retro-placental hematoma view, the detrusor theory, and the view that separation of the after-birth is due to a disproportion in size between the placental area (where it is attached to the uterus) and the placental site (placenta itself). In the settlement of this question there must be guided by evidence afforded from two sources: clinical experience and sectional anatomy. Professor BYRNE pointed out the special value of the sectional anatomy of the third stage of labor and showed that the original observations in this direction made by Dr. BARNARD of Edinburgh had been fully confirmed by FANTOLINI of Milan, STRASS of Berlin, and FINKEL and VARNIER of Paris. It had thus been demonstrated that the placenta did not separate until the third stage of labor, that it then could contract to almost one-half its size without separation taking place, that there was no hemorrhage behind the placenta, and that there was no cavity in the uterus beyond that occupied by the after-birth. In the management of the third stage of labor some had urged an expectant plan until nature herself expelled the placenta; others (ATLFIELD) advised waiting ten hours. The objection to this treatment were stated and CHAMBERLAIN's method and the "Dublin" plan were very fully described and commented. Professor BYRNE said they must try to allow the placenta to be separat-

ed by the uterus itself, and the uterus when this had retracted and when the upper, thick, anterior, contracting portion of the uterus had driven the placenta into the lower uterine segment (which was expansive and passive) or vagina that pressure from above the axis of the birth should be made to expel the afterbirth. He pointed out how they could ascertain clinically that there was separation of the placenta. In most cases the uterus by its retraction and contraction effected this itself; in a few cases gentle massage was necessary. In conclusion, he recommended as the best way of conducting the third stage of labor: (A) following down the uterus when the fetus was being expelled, (B) the constant control of the uterus by the hand; (C) the turning of the patient on her back after the birth of the child, (D) waiting if possible, for nature to separate the placenta; (E) then expression of the afterbirth; and (F) the continued control of the uterus with the hand until the binder was applied.—*Lancet*.

Distemper of Dogs as a Cause of Puerperal Fever.

A case reported by Dr. GOTAVIUS BEVEN suggests that the virus of distemper may be directly contagious to human beings. Briefly stated the author was called to confine the wife of a kennelman whose cottage adjoined the kennels where a number of the dogs had distemper. Two of the dogs being seriously ill, the keeper had to be in such close attendance on them that he could not find the time to even change his clothes when he came in from the kennels to see to his wife, who had just been delivered of a male child. This was her eleventh confinement, the perineum was intact and there was very little bleeding. Soon the next two days she said she was quite comfortable, her pulse and temperature were normal, and the lochia perfectly sweet (i.e., on 9th March) but on 11th March (two days later) her temperature ran up to 104.2 °F and her pulse to 132, and despite careful attention she became delirious, and gradually sank and died on the 26th March. The drainage of the cottage and kennels was all that could be desired, and there was no history of the nurse, who attended her, having been near a woman suffering from puerperal fever; nor had typhoid fever occurred, for some time, within a radius of 6 miles of the place, but enquiry elicited that on the afternoon of the 9th March the husband had, contrary to instructions, come direct from the kennels to see his wife with whom he sat for some time and slept on the bed by her side during the night. Though Dr. Beven would not like to positively assert that this was a case of puerperal fever caused by distemper organisms, he thinks the clinical history rather suggests that view.—*Lancet*.

Submucous Uterine Fibroid: Operation under Grave Conditions: Ultimate Recovery.

I. OR. FLATON has operated upon a patient who had suffered for five years from nearly continuous hemorrhages and all the classic symptoms of a uterine fibroid. She was profoundly anemic, and nearly cachectic. Two tumours were felt in the abdomen one was median, and as large as a man's head, the other was at the left side, and was much smaller. The patient was not operated upon at once, in the hope that her general state of health would improve; but the hemorrhage continued, and the temperature began to rise, so the abdomen was opened, and the uterus, containing a large submucous fibroid of the fundus, was removed (total abdominal hysterectomy). The smaller tumour felt at the side turned out to be a small ovarian cyst. The patient nearly died on the table, and required hypodermic injections of cocaine and of Bayon's artificial serum. These injections had to be repeated several times during the first few days after the operation, and recovery was further delayed by the occurrence of three stitch abscesses in the abdominal wound.—*Brit. Med. Jour.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Anatomy of the Anus.

SERJ. B. STROUD notes that (1) the anus is similarly formed among all the mammals, but is most highly developed in man.

(2). The pecten contains the peripheral ends of nerves concerned with a special "rectal sense" and from its dentations (in some people) spring papillae composed of stratified epithelium, nerve elements and a small amount of connective tissue. Those people who possess such papillae seem physiologically superior to those who do not.

(3). Just cephalo-peripherad of the pecten of some persons are developed more or less extensive anal pockets, which, though not pathologic, may be torn by hard faeces causing lacerations of the pecten which may ulcerate by continued irritation of a fistula or perforation of its floor may result on hard faeces lodging in these pockets.

(4). Rectal reflexes may be due to pressure either on the nerve elements by congested blood vessels or on irritated papillae by spasm of the sphincter, and though they are often injected with serum there is no evidence of sclerosis in irritated papillae.

(5). The nerve supply of the rectum and anus is derived from both the central and the sympathetic nervous systems, and consists of (a) small nerve cells with anastomosing dendrites forming the epidermal plexus, (b) large ganglion cells in the dermis and amyolipic nerve fibres.

(6). There are but few sensory nerve elements in the rectal mucosa whose caudal border is at the linea dentata where the character of the epithelium changes markedly and the mucosa is thrown into folds like a ruffle.

(7). The incontinence of faeces that follows operations for haemorrhoids is due to the excision of the pecten which forms the ventral part of the floor of the rectal ampulla, when the sphincters are closed.—*Canad. Pract.*

Relationship between the Testicles and Prostate.

B. FLODERUS draws the following conclusions A. Effect of bilateral removal of the testicles. 1. If undertaken before puberty, aplasia results. 2. In adults a prostate which before operation was not pathological shrinks after the operation. 3. In cases of beginning or developed prostatic hypertrophy the influence of the operation is less uniform and at times not demonstrable. The diminution in size is greatest in the upper part of the organ. 4. Tuberculous processes, as well as chronic prostatitis, may be brought to a standstill or even cured by the operation. B. Effect of unilateral removal of the testicle. 1. If the prostate be normal, the operation as a rule causes an atrophy of the corresponding lobe, which is noticed principally at the upper half. 2. The operation will not prevent the existence of prostatic hypertrophy. 3. Existing hypertrophy is influenced only now and then, and in those cases in the corresponding lobe. 4. Tuberculous processes in the prostate lobe of the same side may be brought to a standstill and at times cured. 5. The opposite prostatic lobe is not influenced, which fact leads us to suppose that the nerves (sympathetic, sensory, trophic) play a part here. 6. As a rule, the operation causes atrophy of the corresponding seminal vesicle, as well as compensatory hypertrophy of the opposite testicle and seminal vesicle.—*N. Y. Med. Rec.*

Examination of One Hundred Cases of Typhoid Fever by Widal's Serum Test.

Drs. J. COTVILLS and W. D. DUBREUIL divide the cases into two divisions, viz. : Those clinically typhoid and clinically non-typhoid, sub-dividing the first into four classes : (a) Reaction immediate and complete. (b) Reaction incomplete, but complete, or nearly so, when retested at a later date. (c) Reaction incomplete, but not retested. (d) No reaction. The total number of cases in this division was 106. Of these, 84 gave a complete reaction, 12 an incomplete reaction, more complete subsequently; 7 an incomplete reaction, not retested; while in 2 cases there was no reaction. The second division comprises : (1) Cases clinically doubtful at the time, which subsequently ran a non-typhoid course, total, 13, all giving no reaction. (2) Cases certainly not typhoid; total, 7. (3) Cases who had suffered from typhoid at a previous period, total 3. Thus, of 106 cases of undoubted typhoid fever, only 2 failed to give reaction; while of 20 non-typhoid cases only 1—a case of typhus fever—reacted. The last case can only be explained by supposing that the patient had had typhoid fever at some previous date. Another case of typhus fever tested on the same date gave absolutely no reaction, which accords with the views of others. A case of malaria was tried with the serum, both during and after a paroxysm, but no reaction followed.—*Post Graduate*

Biologic Differences between the Bacillus of Eberth and the Bacillus Coli.

At the meeting of the Hospital Medical Society held on 19th March, M. L. TOINOT and M. GEORGES BROUARDEL said that there were very marked differential characteristics shown by cultures of these two micro-organisms in peptonised bouillon containing some arsenous acid. The bacillus of EBERTH exhibits no growth in bouillottes containing more than a centigram of arsenous acid to the liter. It is equally impossible to train this organism, even if the observer begins with bouillottes very much more feebly arsenical and goes on by slow degrees to those more strongly arsenical, to grow in a bouillon which is of a higher arsenical strength than one centigram in the liter. The bacillus coli, on the other hand, from the very first, from whatever source it may be derived, grows well in bouillon containing 1.5 gram of arsenous acid per liter. Certain samples will even grow from the very first in bouillottes containing 1.75 or even 2 grams of arsenous acid to the liter, and this appears to show that this bacillus exists in various kinds, as opposed to the one kind of the bacillus of EBERTH. The bacillus coli is, on the other hand, remarkable for the ease with which it can be trained to grow in an arsenous environment. It is possible by beginning with a bouillon of the arsenical strength of 1.5 grams to the liter to gradually get it to grow in a medium containing arsenic to the strength of 8 grams to the liter. Between an organism of this kind, which is so resistant to an enormous dose of arsenic, and the bacillus of EBERTH, which is incapable of developing in the presence of the very small proportion of 1 centigram of arsenic to the liter, there is undoubtedly a remarkable biologic difference which may be added to those already noticed, such as the indol-reaction and the lactose fermentation test, and which stands on the same footing. The same biologic reaction in the presence of arsenous acid offers a method of differentiation from the group of the paracolon-bacillus.—*Phil. Med. Jour.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Why Inquests are Held.

ACCORDING to the *Manchester Evening Chronicle* Mr. SIDNEY SMELT has been explaining to a coroner's jury at Manchester for what purpose inquests are held. He said that they were not scientific inquiries into the cause of death, though many people thought that such was the case, and unfortunately the idea had been fostered by medical men. Whether they wanted to obtain scientific knowledge from such inquiries or whether they desired to get *legal* giving evidence was best known to themselves. In no case was a coroner's inquiry a medical inquiry and medical men had nothing to do with it except to give evidence when called upon. Inquests were held to find out whether anybody was to blame for death, and he was sure the public, for whose protection they had been established, would strongly oppose the holding of them for scientific purposes. If they were to have scientific inquiries they must have them in every case of death. It was not right that medical men should force themselves upon a jury merely because death had been sudden. Such was not the intention of the Legislature. Nobody ever imagined that a coroner's inquest was a scientific inquiry; but as Mr. SMELT allows that their object is to find out whether anybody is to blame for the death, how is this desirable result to be arrived at without medical evidence as to the cause of death? Supposing the body of a person is found in a stream or a pond, who is to say whether he or she was alive or dead when he or she got into the water except a medical man? Of course if a man is out to pieces by a train or a tramcar there is no need of medical evidence, but there is great need in cases of bodies found dead or in the case of persons who have died without proper qualified medical attendance. We should be glad to know too, what Mr. SMELT means by implying that medical men force themselves upon a jury? It is the duty of the coroner to summon medical evidence if he thinks proper.—*Lancet*.

Dangers from Intermarriages.

Dr. DENEFPS says that the bad results of consanguineous marriages have been observed since ancient times. In breeding animals the principles of consanguinity have enabled us to emphasize characteristics that would otherwise be lost; it has permitted the creation of certain races, but this consanguinity has no value unless it is governed by those competent to choose their subjects. Without this selection consanguinity in animals gives as bad results as in man. With animals as with men it emphasizes the defects and vices. The selection so easy with animals is impossible with man. In our civilization, in these times of alcoholism and neuroses, there are not many families without defects, and heredity also complicates consanguinity. Experience shows us that consanguineous subjects, who seem exempt from all defects, reproduce in their offspring the defects of distant ancestors. It is difficult to get a thorough knowledge of the individuals themselves, and impossible to know much of their ancestors. There are villages in which consanguineous marriages are frequent, and where the race is nevertheless fine and vigorous. Dr. DENEFPS gives many absolutely contradictory facts. He refers to the Protestant communities living during the sixteenth century in the midst of Catholics, and forced by this circumstance to tolerate consanguineous marriages. These marriages gave worse results than crossed marriages. The author considers that consanguineous marriages are always dangerous.—*Gillard's Med. Jour.*

Importance of the Toothbrush.

A **clean mouth** is one of the essential conditions of a healthy body. The best way to secure healthiness of the mouth is frequent thorough cleansing. The following description of what a toothbrush should be taken from an American dental journal:—"The proper toothbrush is the one which will, by its shape, reach as nearly as possible all parts of the mouth and all parts of the teeth in the mouth. The handle part should be a little curved in a shape, the bristles being on the inner side of the curve and set in tufts, not close together, and because of this fact they should be very stiff. That a closely set brush becomes very filthy anyone may convince himself by taking one of these brushes after it has been dirty for a few months by parting the bristles and looking closely into it. With an open brush this condition does not exist, because the construction of it allows thorough washing and a thorough circulation of air, and consequently a thorough drying of the brush and return of a rigidity of the individual bristle and series of bristles. The curved shape of the handle is for the purpose of bringing the brush end more easily under control of the hand while using. At the extreme end of the brush a larger and longer tuft of bristles should be placed, enabling the user to reach more effectually the palatal and lingual portions and surfaces of the teeth, as well as the posterior aspect of the molars. The brush should always be thoroughly washed in running water if possible, the water forced out by drawing the thumb over the bristles and after that dried upon a towel. Three of these brushes should be in use at a time, and consecutive, thus allowing in the interim sufficient time to dry the bristles, making them more effective in their turn for use. The brush to be effective should be used in every direction, and particularly should the movement be in a vertical manner, brushing down upon the upper teeth and up upon the lower teeth, allowing the stiff and scattering bristles to go between the teeth to remove every article of food finding lodgment there. One should not be afraid to brush the gums at the same time, even if they should bleed; the more blood, the more is brushing to be recommended, thus relieving congestion by depletion.

Death from Santonin.

LAST week (16th April 1898) Mr. WHEEDON, coroner, held an inquest on the body of Mrs. HUMPHRIES, wife of a groom, who had died the previous day from the effects of an overdose of santonin, accidentally taken. It appeared from the evidence of her husband that deceased had an idea that she had "something alive inside her" for the past seven or eight months. She took different patent medicines, but to no purpose. She was an out-patient at the Royal Berkshire Hospital for six weeks, but did not get better. About six months ago a neighbour told her to get some santonin, which she did and took some doses, after which she "acted like a lunatic," and continued to have fits until half an hour before she died. About a quarter of an hour before she died she told him she had taken all the empoison, of which he thought there was quite 2 drs. Dr. TAYLOR, who attended deceased, was questioned. On her regaining consciousness he questioned her and found she had taken the powder, which was a powerful poison, and was often used in very small quantities as a worm-powder. She had the appearance of having taken poison. On examining deceased just before her death he found she was suffering from an internal tumour. The jury returned a verdict of death from poison, accidentally taken.—*C. & D.*

Therapeutics and Hygiene.

Veratrum Viride Lotion for Eruptions. *Fever Blisters, Boils, Follies, &c.*

Dr. WILSON A. SMITH, Chicago, calls attention to the efficacy of *veratrum viride* when applied locally to eruptions. Dr. F. J. BOUTIN twelve years ago finally applied *veratrum viride* with two parts of water to a vesicular eruption on the face. The relief from pain was marked, and the improvement continuous. Since then he has seen nothing else give the relief that can be obtained from a non-alcoholic lotion of *veratrum viride*. In case of *fever blister* (or "gold sore") on the lips which ordinarily last a week or more, a few applications of *veratrum viride* lotion cures usually in twenty-four hours. He now uses a fluid extract, as it requires no dilution to avoid the irritating effects of alcohol, as does the tincture. It must be used early. The same benefit results from its application to inflamed pimples and minute abscesses about the face. Boils treated early can often be aborted by *veratrum* locally, as above. He has seen several instances of "follies" cured in a day or so by the same application. Keep the inflamed finger constantly wet with the fluid extract. It relieves the local fever and has a soothing and beneficial effect in nearly all conditions where there is a local external inflammation.—*Ver. Med. Semi. Monthly.*

The Sun Cure.

It is claimed for the sun cure, which, like the rest cure to which it closely allied in many ways, may very easily be tried at home, that the results produced by it are more lasting than from other tonic. A sunny window, an easy chair or sofa, and just a little resolution or determination are all that are required for this treatment which is to strengthen and beautify men and women. The improvement in looks and spirits that usually follow a sea-side or camping out season and the peculiar yet attractive softness of a skin that has just recovered from a severe case of sunburn and tan are advanced in support of the health and beauty-giving properties claimed for the sun cure.—*Med. News.*

Iodine Injections for Malarial Hypertrophied Spleen.

PANOMA considers hypodermic injections of the following solution the simplest and most effective treatment for hypertrophied spleen of malarial origin at our disposal to date. Metallic iodine, 25 centigrams; potassium iodide and guaiacum 25 grams; pure sterilized glycerine 25 grams. Inject one gram in the flank or back, the patient remaining in bed during treatment, suspending it as the organism becomes saturated with iodine. Four cases of enormous tumefaction of the spleen are reported practically cured, although one case required splenectomy later, on account of the mobility of the organ.—*San. Med.*

Buckskin Dressing for Eczema.

DAYENAG has found that buckskin applied over the calve fits smoothly to the surface, yielding to every movement, never rote nor produces erythema, does not absorb the calve and does not stick to the tissues, while it is easily washed and keeps the dressing moist inside and dry without, and the scales leave a healthy surface when they drop off.—*San. Med.*

Carbolised Adhesive Plaster.

L. ANDRIAY gives the following formula:—

R Simple adhesive plaster, ... 10 parts.
Carbolic acid, ... 1 part.
Miz.

Preparation of Universal Plaster in General Formulation.

ARRIENHOUT recommends the following:—Potassio-ferric tincture, 1 gram; fracture of wax tapers, xv to xx drops; decoction of ipecacuanha and decoction of cinchona, aa 100 grains; to be taken by tablespoonfuls during the twenty-four hours.—*Sci. Med.*

Maltreated Adhesive Plaster.

R Simple adhesive plaster	...	95 parts.
Maltreated acid	...	2 "
Lard	...	3 "

Melt the plaster and add the acid and lard mixed.

Iodoformized Adhesive Plasters.

1 (ten-per-cent).		
R Lead plaster	...	65 parts.
Snut	...	10 "
Dammar balsam,	{ each	7 "
Pine tar,		
Vandoe-turpentine	...	1 part.
Iodoform, in very fine powder	...	10 parts.

Melt together all the ingredients except the iodoform, allow the mixture to cool, and when it is almost solid add the iodoform.—*Journal de médecine de Paris.*

Aromatic Tinct Vinegar.

Rectified spirit	...	6 oz.
Oil of bergamot	...	25 min.
Oil of lemon	...	25 min.
Oil of orange	...	10 min.
Oil of rosemary	...	20 min.
Oil of lavender	...	3 min.
Oil of melissa	...	5 min.
Aqueous decoction of 1 dr. each of benzoin, tolu, styrax, and colves	12 oz	
Vinegar	...	4 oz.
Acetic acid...	...	1 dr.

Macerate one week and filter.—*Merck's Report*

Cream-Embrocation.

Oil of sassafras	...	1 oz
Lard oil	...	5 oz.
Cotton-seed oil	...	1 oz.
Spirit of turpentine	...	3 oz.
Solution of ammonia	...	5 oz.
Oleic acid	...	1 oz.

Mix the acid and the lard and cotton-seed oil. Then add the turpentine and ammonia and shake, lastly adding the oil of sassafras.

Aromatized Cod Liver Oil.

DUQUENEL's formula is given as follows in the *Revue des maladies de l'enfance* —

R Amber-colored cod-liver oil	...	100 parts.
Oil of eucalyptus	...	1 part.

M. This mixture is said to taste only of eucalyptus and to be free from any disagreeable odor.

Hair Tonic.

DIETRICH recommends the following wash. Quinin hydrochlorate, 4 grams; tannin, 10 grains; alcohol (80 per cent.) 500 grains; Cologne water, 20 grains; vanillin, 10 centigrams; pink sandal wood, 5 centigrams. For external use. Set aside five days and filter. Apply and rub well into the scalp every other day.—*Prog. Méd.*

Correspondence.

A MEDICAL REGISTRATION ACT FOR INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following Editorial from the *Bengal Times*, the great advocate of reform, justice and equity, will be read with keen interest by every reader of the *Record*.—

"It must be extremely gratifying to our Indian Medical Association—Calcutta—says an esteemed contemporary—*Indian Medical Record*—to learn that its laudable efforts to secure a Medical Registration Act for India, though yet not successful, are tending towards success, as they have already engaged consideration of the General Medical Council of Great Britain, and they have attracted the attention of Parliament. We quote from the *B. M. J.* of 28th May:—'Registration of medical practitioners in India was the subject of a question on Tuesday, in which it was pointed out that, at present, uneducated and unqualified persons have freedom to practise in India to any extent. The Secretary of State admitted that this was so, but declined to bring in a Registration Bill, on the ground that it would be impossible to prevent people having resort to native practitioners. In giving this answer, Lord GEORGE HAMILTON was evidently laboring under a misconception as to the nature of legislation asked for. A Registration Act on English lines would not prevent people resorting to native doctors, it would only enable them to differentiate between qualified and unqualified persons, and so to protect themselves against ignorant pretenders. Without a Registration Act, people have no means of distinguishing between a man who really has qualifications, and a man who advertises falsely that he has them; and it is to give natives this power of protecting themselves, and not for a purpose of preventing them resorting to native practitioners, that legislation is required.' We go much further than our medical contemporary, by contending that a false representation of medical qualification, whether by newspaper advertisement, placard, signboard, label, or otherwise, is *illegal*, being a fraud practised on public credulity, which victimises many and may even endanger life and cause its unnecessary sacrifice. In an emergency, a man rushes off to summon medical aid and takes that which is nearest to his hand. He enlists Dr. A to—he being most conveniently near—and discovers when matters are too critical for recall—perhaps, beyond human aid—that this self-dubbed Dr. A has no right whatever to his assumed professional title. He is safe however, from prosecution. Surely, this cannot be intended since life and health are worth more than money, and if we have a law—*Legal Practitioners Act*—under which a man who, by falsely representing himself as a lawyer and obtaining money thereby, becomes liable to criminal prosecution, it seems painfully significant that one who, through ignorance deliberately sacrifices life should be immune from liability. This is an incongruity—if it exist—in our law codes, that calls for urgent remedy, and its importance demands searching enquiry into prosperous imposture. A man who through credulity in assumed professional skill, loses merely his money, can always try to find an opportunity of replacing it, and may succeed, but he who loses a near

relative, or dear friend, through lack of technical knowledge, is not so happily situated, and it seems to us remarkable he should be without redress because of an abuse of confidence practised on his trustfulness. It is not asked to foster inaction—let men choose their own practitioner—but it is imperative that public safety may be vouchsafed. It seems to us that when a choice is allowed legislation of protecting one's money or his life, his purse is regarded as of more value than his existence, in short, a man may kill, on false pretences, but he must not rob."

Yours &c., MEDICAL MISSIONARY.

NEWSPAPER VIEWS ON PLAGUE AND PLAGUE POLICY IN CALCUTTA.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—I quote from the *Indo-European Correspondence*, an English Catholic paper —

"There is now a pretty general consensus of opinion in Calcutta that we have no epidemic plague amongst us, yet the plague party are constantly worrying our nerves with cases of suspected plague which are trotted off to the Manicktollah Infirmary and trotted out in the official papers. The best native medical authorities who have spent a lifetime in treating such fever cases, declare that this bogey of a plague is a sham, which is bound to last only as long as the special funds affected to it will last.

"If it be only a question of spending that money honestly, why not spare our nerves, and rid our streets sooner of the dead rats and cats, which are sometimes left for a couple of days to rot in the open? We dare say such work would fall much better within the province of a Vigilance Committee, than that of plaguing us with a plague which no one is able to spot, and that of soaring away those most useful scavengers, the street sweepers and *dōms*, who are the best preservers of our health and lives

"It is a fact which strikes us very forcibly that, in Bombay, exactly one day after the telegram by which the plague party were said to throw up the sponge and make the town over to the Municipal Commissioners, we received another telegram that the plague is stamped out and the seizures have suddenly fallen to 2!

"But then, it may be asked, has the plague made no victims in Calcutta?

"It has. For several cases of glandular fever, a thing often treated here, preferred dying secretly in their rat-holes rather than being treated as suspected plague patients.

"Again, several poor devils, when smitten with any fever that demanded prompt remedy, fled toward their own country, and died of exposure on the road

"Again several cases, when joggled and jolted in the ambulance-car, died on the way from fright, or shortly after reaching the segregation-shed from exhaustion.

"For all these deaths, not the plague, but the plague party shall answer to God; for the misery of the poor cries up to heaven for vengeance"

We quote from the *Bengalee*, the leading Anglo-native paper of Bengal:—

"As for the plague the students and their parents need not be alarmed. We doubt if there is any real plague in Calcutta. If it is plague it is of a type very different from that of Bombay. It is devoid of that which marks it out as a really dangerous disease, viz., its infectious character. Assuming as correct the official view of the matter, there have been cases in this and other wards, but these have not been followed by similar cases in or near the houses where they have occurred. The cases are not infectious—they are sporadic—it is indeed doubtful whether they are true cases of plague. There is no cause for alarm. The students should come back to their work and not waste their time at home in idleness. That is our advice to them and their guardians."

We quote from the *Indian Mirror*, another leading Anglo-native paper:—

"The Bengal Chamber of Commerce took a fortnight's time, we believe, to consider what action its members should take in reference to the plague, after watching the progress of the disease in the interim. The time has now elapsed and matters, we fear, have become worse since then, for the number of plague seizures and deaths has evidently somewhat increased. An undoubted belief is entertained in certain quarters, that the plague is an established fact now in Calcutta. There are others who are utterly sceptical on the point. This division of opinion prevails among the doctors as well. There are some doctors who still seem to think that they have been accustomed to treat such cases as are now creating so much excitement and alarm, for many years past in Calcutta. Other doctors contend that such or similar cases may be endemic in Bengal, but that the fever which has lately appeared in Calcutta, and is causing such rapid mortality among the patients suffering from it has got about it some peculiar features, which were not observed in fever cases previously. These doctors are decidedly of opinion, that some few true cases of undoubted plague have really occurred in Calcutta, though their number falls far short of the number stated both in the columns of seizures and deaths in the daily returns of the Corporation. And this is so, because the Corporation includes even suspected cases in its returns. The question, then, to be considered is, if the plague has really appeared in Calcutta, what is it due?

"This question is one of so much importance that the Bengal Chamber of Commerce would do well to look carefully into it. We do not care so much for the plague itself, as to be quite sure if it has really broken out in this city. What the people chiefly complain about at present is in reference to the treatment of suspected cases. There are cases, the history of which is known thoroughly to the friends and relatives of the patients, and the nature of which they cannot have the slightest doubt about. And yet, to their utter surprise and bewilderment, some of these cases are taken as suspected cases or even as those of real plague. The best thing to do, under the circumstances, is to remove all causes of complaint on this score, and to have all such cases examined and pronounced upon, not by a single Bombay doctor, but by a duly constituted and competent Medical Board. The Bombay doctor's verdict ought not to be final, for it does not quite satisfy the public, especially, when his examination is unaccompanied by any bacteriological investigation. It matters little whether the doubt is well or ill-founded. But, we think, it is due to the people, that a competent and independent Medical Board should be at once appointed by the Government to supervise the work of the Health Officer and the plague doctors, and to constitute a body, which, by its weighty pronouncement, will satisfy the public as to the true merits of each reported case. And this has become all the more necessary in view of the malicious and mendacious information, anonymously supplied to the Health Office about bogus cases. We trust the Bengal Chamber of Commerce will take up the matter with its wonted energy."

Yours &c., FAIR PLAY.

ON THE C. D. QUESTION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I have no intention of prolonging the discussion, and only write because one or two questions have been put to me. Some of them do not require an answer. "Medical Man" does not surely want an answer to such a one as "Does he maintain that the preferable course is to leave them to rot?" And the reader can judge of the fairness or unfairness of his criticism of the Lady Doctor's statement that "it lies to a large extent within the power of the individual to avoid infection." I threw no mud. I took the facts supplied by their party and asked them to think over the results of their handiwork. I think he should keep to the 8,000: he used it in good faith. The figures I turned up and found to be 6,190 as supplied by the Government, and the use he made of them is the use they try to make of them.

He writes: "Can Dr. HUNTLY give me a single case where his methods have been tried and proved successful? It is this question and one other statement which makes me take up the pen."

I am sorry to say that, the authorities in India have given no method but their own a chance—for over thirty years, remember—and the result is failure and fraud. These two words sum up their method. They had during many of these years a free hand, and faults in their construction, &c., were not largely due to "Dr. HUNTLY's friends," and non-success is their own written verdict as the "Burmah" statistics verify afresh. One more recent proof of their non-success, *Lancet*, 26th March, Army Medical Report; total ratio from venereal disease in 1897 is 173.7 per 1,000 against 134.5 in 1896. There the C. D. Acts have never been repealed.

In South Africa, General GOODENOUGH tried anti-C. D. methods, and there I would direct "Medical Man's" investigation. I have not the figures beside me, but it is a victory of anti against pro C. D., showing what can be done by a good officer.

"A Medical Man" knows that outsiders cannot attempt any methods; they can only be carried out from within by the co-operation of the Army Commanders.

It is silly, childishly silly, for "A Medical Man" to say we only coolly assume that God is on our side. He knows what is meant in this great moral question with world-wide racial issues when we say that God's position is clear. It is painful to read such trifling. It is because in the abstract, and as we hold, in all that is practical issuing from the abstract, these principles have God on their side that the higher nature of "A Medical Man" says he has admiration for these views.

He touches new ground when he says they are "unpracticable." That is to be tested; we see clearly many difficulties, and perhaps one of the main difficulties is the difficulty of co-operation of officers. "The officers are even worse than the men." This reads like a reckless statement. How far from or how near the truth I know not, yet it is the opinion of a Colonel of a regiment in India, uttered across the dinner table in a conversation over the Regulations. All the greater need of the officers themselves being roused on this question. *Apropos* of the attitude of officers on cognate questions, here is another incident: a great noise is made over the encouragement to temperance in the army, and all honor to those who by example as well as precept help; but the following can happen even in these temperance days, and in this year of grace. A company were on the march and a daily allowance of beer was granted. The abstainers asked that an equivalent for tea should be granted to abstainers; this modest request was refused! However, the soldiers themselves stuck to their guns and their principles and only an odd man or two relapsed. All praise to T. A., none to the officers. But while the officers may be a difficulty, the real contest is not on a minor issue but with State legislation which raises an immoral traffic into the position of a lawful industry superintended by Government officials.

Yours &c., W. HUNTLY, M.A., M.D., B.Sc.
NUSSEERABAD, 20th June 1898.

PLAGUE HUNTING IN CALCUTTA AND ITS DIRE RESULTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Dr. BLANKY, of Bombay, writes as follows to the *Times of India*:—"Our second plague visitation has nearly declined to the vanishing point, and I still find 'search parties' at work hunting for plague cases in people's houses, and worrying and terrifying the weak and the timid, the very persons who are most in need of being permitted to live in peace. In your plague column to-day

I find a notice of one of these plague hunters which closely resembles a rat hunt, and after a two hours' run the searchers found 'no case of plague in the district.' What then is the justification for this barbaric interference with the people in their homes? Let me ask these plague hunters, or rat hunters, what earthly good can possibly result from their sneaking into houses and disturbing and distressing inoffensive people? Do they suppose they are stamping out a plague or preventing its spread to Calcutta? Does any one of them know anything about plague infection and how and under what circumstances this infection is conveyed to man? Can any one of these plague hunters produce one atom of evidence that their hunting has diminished the number of plague cases by one single unit? Do they not know, or have they not heard that the whole sanitary world have set their faces as a flint against compulsory segregation? Nay, they know nothing about plague and its way of infection. All they do know is the fun derived from hunting up real or imaginary cases, and of disturbing whole households in whole districts. It may be fun to them, the hunters, but it is nearly death to their quarry, and if they are natives they know the injury they are doing. I protest in the name of humanity against a continuance of these plague hunts, and would recommend the hunters to study the science and details of the business to which they have voluntarily apprenticed themselves. Novices all, incompetents all, in the very great subject of plague prevention and plague abatement, will none of the friends of these hunters be kind enough to try and persuade them that they have mistaken their vocation. Whatever else they may be fit for, nothing is more certain than that they are quite unfit for abolishing or abating plagues. I did hope that these misguided hunters would in time see their own failures and recognise their own cruelties, but as they persist in carrying on their oppression to the bitter end, with the chances of that stupid oppression being continued long after the city is free of plague, I feel justified in making this loud and very strong protest against our organised city tormentors.

"If those hunters want laurel decorations and evening parties, let them come to me to get up the *tamasha*. This suffering city has found no saviours in the time of its dire distress. What it has found has been ignorant tormentors under the guise of philanthropic friends, so-called friends, subservient friends, ignorant friends amongst their own people."

Yours &c., EASTERN GUARDIAN.

—O—

OFFICIAL PLAGUE—A PROTEST.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The annexed is the official text of Dr. WALLACE's protest regarding the present plague question in Calcutta at the meeting of the Municipal Council in the Town Hall on the 4th May 1898. It is extracted from the Municipal Proceedings Report, page 22, and is as follows:—

"Dr. WALLACE said he had listened with considerable attention to what had fallen from Dr. SANDERS, and what he had said was in absolute conformity with an official letter sent to the Bengal Government by the Council of the Indian Medical Association. It was there pointed out that the subject was surrounded by considerable difficulties with regard to the social relations of the Hindu and Mahomedan communities. And having regard to what had first been said he could assure the members of those communities that the European community was in entire sympathy with them, and that they might rely on the support of that community. With regard to the disease itself Dr. WALLACE referred to the rules laid down by the Government. If, he said, it was a fifth disease Calcutta had had it with them for a century. Filth was always with them in abundance; and from the very fact of the conservancy of Calcutta being so generally condemned, if it was a fifth disease, the plague should have been

in Calcutta long ago. But when the *Madras Journal* in discussing individuals here was pronounced on a former occasion not to be the plague disease, the idea that the plague was a *filth disease* died a natural death. On the present occasion, while there was a difference of opinion whether there was plague or not—and some were prepared to say they were not cases of plague—the community was placed at the mercy of an eminent man who was now at Bombay. Strange it was that Calcutta was absolutely without a bacteriologist, and therefore there was neither confirmation nor denial of the opinion of M. HAFKIN, who was not a medical man but a chemist. With regard to segregation there was nothing to show that it had the smallest effect, and with regard to inoculation it was an experiment, and there was not a consensus of opinion that it was a prophylactic and a preventive from disease. Dr. WALLACE denied that the time had yet come when it could be pronounced a success. The faculty had not arrived at a definite conclusion with regard to inoculation. The time had not come when it should be forced upon the people as an absolutely safe preventive of plague in the sense that vaccination was of small-pox. It was premature and dangerous that inoculation should be fostered by the Government until experiments had been made all the world over. It could not be pronounced a success because in Bombay and a few local centres it had been tried with some effect, and Dr. WALLACE thought the Corporation ought to protest against inoculation being considered safe in any sense of the word.

Yours &c., MUNICIPAL COMMISSIONER.
CALCUTTA, 22nd June 1898.

THE PLAGUE AND HAFKINISM.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Not being a believer in the now-fangled but in reality more than antiquated theory of "taking a hair of the dog that bit you" as a cure, I am quite at one with you in contesting the value of M. HAFKIN's plague treatment, for which there is not much corroborative evidence. The horse is immune (i.e., not predisposed) to plague, and there is no true precedent for saying that because the horse did not die when inoculated with plague virus from man, a man will not get plague if inoculated with serum from a so protected (???) horse. If a single instance were known where, as in small-pox vaccination, inoculation with plague serum induced a mild attack of that disease, we might have a little faith in the prophylaxis of Hafkinism; but such evidence is not admissible.

Study the records of PASTEUR's antirabic inoculations. Many persons died of rabid convulsions who might still have been alive and not at all developed hydrophobia had they even had no sort of treatment. Five Europeans residing in one house were so slightly bitten by a rabid pup that they took no notice of it. Two of these died of hydrophobia, while the other three did not at all. On another occasion, a young lady was bitten in my house by one of my dogs that seemed peculiar. Her friends insisted on my destroying the animal on the plea that it subsequently becoming rabid would make the girl mad; but I sent the dog to a friend who afterwards shot it because it became rabid. The young lady suffered no ill consequences from the bite. Again in my many years of service I have repeatedly seen the soldier bitten and as often treated them for dog-bite without any of them getting hydrophobia from it. Once I felt very nervous and even could not bear to hear the splashing of water after a man in the last stages of hydrophobia, but in my eye, but I overcome my horror and fears by taking very long and fatiguing walks.

Again, it is quite a common thing for cavalry horses to be bitten by dogs, but I have never heard of antirabic inoculations being employed to protect the thousands of Government horses from hydrophobia to which they are not immune.

Yours &c., SUBJON-LIEUTENANT.

(As a matter of fact, Hafkin's inoculation does produce mild symptoms of plague or blood poisoning.—ED., I.M.R.)

TREATMENT OF CHOLERA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following is a brief account of the measures I successfully adopted in the Hansot cholera outbreak, which lasted for a full month and commenced with a male *koli* who had been to Broach in a law suit, but immediately on his return to Hansot manifested cholera to which he succumbed within 12 hours. After this there were 22 cases of which 6 terminated fatally.

As soon as a patient came in with cholera I gave him 3iv (repeated every 15 minutes) of the following mixture—R Carbolic Acid mvi , Spts. Camphore and mist. diarrhoea aa 3ix, and Aque Chloroform 3vj. The first dose was invariably rejected, but the second was retained and vomiting and purging ceased after the fourth or sixth dose.

The limbs were rubbed with compound campher liniment to relieve the violent cramps, and to enbduce the excessive thirst a pinch of a powder made by rubbing Sodii Bicarb grs xl, Sodii Tart. 3j, Pot. Tart. Acidii 3ss, with Acid Tartaric grs. xxxv, was thrown into a teaspoon or two of water and given to the patient while effervescing. In one case, that of a boy of 9 years who was almost collapsed, I had to administer two hypodermic injections of 1 grain of chloral hydrate dissolved in 10 minims of water. The various excreta were mixed with dammar and straw and burned instead of being buried.

Yours &c., SAMALDAS NAHANJI, C.M.S.

In medical charge, Hansot Diapensary.

(What is the formula of your Mist Diarrhoea?—ED., I.M.R.)

PATENT MEDICINES AND THE "BANGAVASI."

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It is to the lay press—the vernacular chiefly—that the masses look for information, and if the newspapers lend themselves to puffing up patent medicines called into being and offered for sale by persons who are utterly ignorant of medicine and its allied sciences, the uneducated and those of the educated also who have never learned the truth of the proverb "the loudest brag are the greatest liars and biggest cowards," must continue to be duped by the glaring advertisements of the marvellous properties of this patent medicine or that whose real virtues lies in undermining the health of the recipient and fleecing his pockets to fill the associate coffers of the unscrupulous advertiser.

It is deplored throughout the length and breadth of India that, so far, there is neither prophylaxis nor certain cure for "plague," and yet if you take up the *Bangavasi*, which has the largest circulation of all the Bengali vernacular papers, and you will be surprised to note that one Mr. B. BART, who is not a doctor, not a *Kavay*, nor even a *Hakem*, has actually discovered two great specifics, the

one for the cure (*sic*) and the other for prevention (*sic*) of plague. If this were only true, what a boon for the thousands of India; but who is this Mr. B. BASU? A specialist? Scarcely! A greater than HAYKINS and wiser than the whole of the medical fraternity? No! But the brother of the proprietor of the *Bangavasi*, who ought not to lend his paper to deluding his credulous subscribers.

Yours &c., HARA KALI SEN, C.M.S.
RAIGANG, 4th June 1898.

HIGHLY PLACED ANGLO-INDIANS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I beg to send you a few more names for the list of highly placed Anglo-Indians which you are publishing in your valuable paper:—

1. Captain W. Newell, Indian Staff Corps.
 2. A. B. Jervis, Principal, Mission High School.
 3. C. Tudball, Bombay Civil Service.
 4. Sidney Percy Leggett, Barrister-at-Law, Karachi.
 5. T. Fernandes, Superintendent of Surveys, Kathiawar.
 6. Walker Harold Brook, Superintending Mechanical Engineer, Umari Colliery.
 7. W. P. Arthur, Superintendent, Aden Police.
 8. W. J. Hemson, Registrar, Bombay Secretariat.
 9. J. Cross, Registrar, Bombay Secretariat.
 10. Anthony Brown, Superintendent, Revenue Commissioner's Office, Poona.

Mr. F. Lavery, Registrar, Dewan's Office.
Mr. St. John Buchan, Examiner, Public Works and Railway Accounts.

Mr. J. Chapham, Deputy Registrar, Chief Court.
Yours &c., ANGLO-INDIAN.

SOME MEDICAL APPOINTMENTS FOR MILITARY ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Anent the retirement of Surgeon-Major HONGKINS, who has so ably and successfully held the appointment of Superintendent, Military Medical Cadets, Medical College, Calcutta, for many years, I beg to draw your attention to yet another important State appointment, viz., that of the Chief Medical Officer of the E. B. S. Ry., which might profitably and successfully be filled by a Commissioned Officer of the Military Assistant Surgeon Class or a (1st Class Military Assistant Surgeon over 5 years). A suggestion to this effect has already appeared in the press, and I now write to you in the hopes that you may interest yourself in the matter, so far as to bring pressure to bear on Government.

Yours &c., ONE INTERESTED.

THE SUN LIFE INSURANCE COMPANY OF CANADA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you be good enough to publish the following correspondence in your journal:—

Yours &c., JAMES B. WALLACE.

CALCUTTA, 27th June 1898.

DR. JAMES R. WALLACE, M.D., F.R.C.S.

Editor and Proprietor, "Indian Medical Record,"
50 Park Street, Calcutta.

DEAR SIR,

We are in receipt of your letter of the 16th instant addressed by you, evidently by mistake to Mr. D. J. WADIA instead of to ourselves, and have seen our clients on the subject thereof. Our clients are unable to accept your explanation, as in any way satisfactory. They find that in the same breath that you tender an apology you try to justify the libel, and this is confirmed by the demand that you make in paragraph 4 of your letter for a complete answer to the interrogations made by your correspondent with a view to publish the same in the next issue of your pamphlet. Our clients cannot accept your statement, that the letter of your correspondent was published in good faith and for public good, but they repeat that the letter published under the heading of "Bogus Insurance Companies" and with the editorial foot-note attached thereto by you is a positive libel, falsely and maliciously published, and cannot but injuriously affect their business interests and their character and reputation as one of the best Insurance Companies doing business in India. Our clients deny your right to make the demand made by you in paragraph 4 of your letter, and do not consider themselves bound or called upon to answer any interrogations which are made in the public press or pamphlets. They would however be too glad and happy to satisfy any honest and *bona fide* enquiry that may be addressed to them. We may inform you that, as a matter of fact, your correspondent, M. MANARAWMY IYER, has had some correspondence with our clients on the matter, and our clients have answered his enquiries fully.

Nothing short of an apology as per enclosed form will satisfy our clients; unless therefore you tender an apology to our clients in the form enclosed and agree to publish it in the next issue of the *Indian Medical Record*, we have positive instructions to proceed further in the matter as already intimated to you at your risk as to costs and consequences.

Yours faithfully,
(Ed.) EDGELOW and GULALCHAND.

13, Old Post Office Street, Calcutta, 4th June 1898.

Messrs. EDGLOW & GULALCHAND,

Solicitors, Bombay.

DEAR SIRS,

Sun Life Assurance Company of Canada.

DR. WALLACE, the Editor of the *Indian Medical Record*, has handed us your letter of the 10th ultimo with instructions to reply thereto.

Our client's former letter was addressed to Mr. WADIA, because it was that gentleman who wrote to our client.

Our client is advised that there is nothing libellous in what he has written, nor is there anything of that nature in the letter from his correspondent which he published. However that may be, our client has stated in unmistakable language that he had no intention to defame your clients, and he has expressed his regret for and withdrawn anything written that may be construed in such way as to have any evil or harmful effect upon the company. Our client has, moreover, published this letter in the *Indian Medical Record*, and we contend that he has done all that he can be expected to do to remove any wrong impression that might be created. We would point out to you that for our client to say he accepts the advertisements of none but genuine Insurance Companies in the *Record* is not to say that your client's company is otherwise than genuine, because it has not an advertisement in that paper. This would appear to be the inference you draw in your letter now under reply.

We trust that under the circumstances you will see that our client has done all that he can reasonably be expected to do in this matter. If your clients after this take any legal proceedings in this matter, they will do so at their own risk.

Yours faithfully,
(Sd.) S. J. LESLIE & SONS.

Bombay, 9th June 1898.

Messrs. S. J. LESLIE & SONS,

Solicitors,

13, Old Post Office Street, Calcutta.

DEAR SIRS,

The Sun Life Assurance Company of Canada

and

The "Indian Medical Record."

We have received this morning your letter of the 6th instant.

The apology contained in your client's letter of the 16th ultimo is not absolute and unqualified, and it is an apology of the latter sort, which is due to our clients. The article published by your client and complained of by ours is positively defamatory and cannot but be harmful to our clients. By publishing his letter of the 16th ultimo in the *Indian Medical Record*, your client has only added an insult to injury, for the demand contained in paragraph 4 of that letter is calculated to leave an impression in the minds of the readers of the *Indian Medical Record*, that there is some information relating to the management and affairs of our client's company which they withhold from the public, and to lead them to draw an inference therefrom, adverse to our clients. Your client has not done what he is bound to do.

We give him this one more and final opportunity to tender an absolute and unqualified apology to our clients for having published the article in question, and to give him this notice through you that unless he does so within 8 days from the receipt hereof by you, and publishes such apology in the next issue of the *Indian Medical Record*, we have peremptory instructions to file an action against him, and he will then have to thank himself only for the consequences of his acts.

Yours truly,
(Sd.) EDGLOW & GULALCHAND.

13, Old Post Office Street, Calcutta, 10th June 1898.

Messrs. EDGLOW & GULALCHAND,

Solicitors, Bombay.

DEAR SIRS,

The Indian Medical Record

vs.

The Sun Life Assurance Co. of Canada.

Your favor of the 9th current. Our client has not qualified his apology in any way, nor had he any intention to do so. He has through us to you, as well through the medium of his journal, expressed his regret and again expressed his regret for anything that has appeared in the *Indian Medical Record*, which might be deemed harmful to the reputation of your client's company, but he cannot and does not withdraw from the assertion that he did not intentionally write or publish anything that could harm that company, nor does he think that anything that has been written or published by him could be construed to be harmful to the reputation of the company in any way. We are further to add that our client absolutely withdraws anything in the foot-note and heading of the published letter that you may consider offensive, and he regrets that your clients should have found anything offensive therein.

This letter will be published in the next issue of the *Indian Medical Record*, the only paper in which the letter complained of has appeared, but our client cannot agree to its being published in any other paper or in any other way.

Yours faithfully,
(Sd.) S. J. LESLIE & SONS.

Medical Trade Notices.

LIQUOR SEDANS.

A UTERO OVARIAN SEDATIVE AND ANODYNE.

PARK E. DAVIS & Co.,

Manufacturing Chemists, Detroit, New York,
and Kansas City, Walthamville, Ont.

Each Fluid ounce Represents :

Viburnum Prunifolium	60 grains.
Hydrastis (represented by the white alkaloid, hydrastine	60 grains.
Jamaica Dogwood	30 grains.

Combined with aromatic.

PHYSICIANS who have given special thought or study to the subject maintain that the conditions of modern life foster uterine and ovarian disorders, and as a result, gynecologists flourish, and medicaments designed to regulating these disordered functions are in great demand.

While many uterine and ovarian troubles can be remedied only by mechanical means or surgical procedures, perhaps the majority are not sufficiently grave to require operative treatment. Among these latter may be classed many cases of dysmenorrhoea and ovarian hyperaesthesia, for the relief of which the patients periodically resort to alcohol, the narcotics, or some of the much vaunted nostrums in the market.

A careful study of medical literature for the past few years and the great importance ascribed by many medical writers, teachers and practitioners to Viburnum Prunifolium (Black Haw) in regulating uterine function; the specific action of Hydrastis (Golden Seal) in the catarrhs accompanying uterine irregularity, and the well-known anodyne and sedative value of Jamaica Dogwood (Picidia Erythrina) and its freedom from the depressing after-effects of opium preparations, suggested to us the propriety of offering a palatable combination of these three remedies.

We offer this to the profession under the name of Liquor Sedans, and feel certain that it will be found a most convenient and serviceable combination for a very large class of cases of dysmenorrhoea, ovarian irritability and irregularity of the utero-ovarian functions.

Supplies furnished to physicians in private or hospital practice, and, at request, and reports, favorable or unfavorable, solicited.

WHAT A LEADING AMERICAN PHARMACEUTICAL JOURNAL SAYS ABOUT STEARNS' WINE OF COD LIVER OIL WITH PEPTONATE OF IRON.

According to the *Pharmaceutical Era* "Physicians are delighted with the new preparation of Cod Liver Oil, recently put on the market by F. STEARNS & Co. of Detroit, Mich. The conception of combining Cod Liver Oil in a palatable shape, with a most assimilable form of iron, is one worthy of the support of all and most certainly is this conception carried out in STEARNS' Wine of Cod Liver Oil with Peptonate of Iron. That the efficacy of the oil is due to alkaloide, has been thoroughly demonstrated, but it has been left for this enterprising firm to present them in a useful shape and thereby obtain the efficacy of the oil, without the nauseating properties so long attributed to it. STEARNS' Wine of Cod Liver Oil can be taken by any one, no matter what his previous experience with the plain oil has been, and when we have the manufacturers' assurance that the preparation represents all of the active medicinal constituents of the oil, and the effect enhanced by the addition of good wine and peptonate of iron, 4 gra. to the ounce, it certainly must be a preparation worthy of the foremost place in the ranks of palatable pharmaceutical productions."

Government Medical Gazettes.

GOVERNMENT OF INDIA.

To be Ordinary Members of the Milly. Divn. of the third class or Companions of the said most Honorable Order :—

Surgn.-Col. Ed. Townsend, A.M.S.
Surgn.-Col. George McBride Davis, D.S.O., I.M.S.

ORIGINAL ARTICLES.

THE SYMPTOMS AND DIAGNOSIS OF PLAGUE.*

By MANSUKHA LAL SINGH, M.D., D.L., C.I.E.

Calcutta.

As the complaint has become very general that people are being forcibly removed from their homes on the merest suspicion, when only suffering from the slightest ailments, we think a description of the symptoms of plague, with a view to show the very great difficulties there are in arriving at a correct diagnosis of the disease, will not be inopportune at the present moment.

The disease may be conveniently divided into stages. Five stages may be noticed in a typical case ending in recovery. These are—(1) the stage of incubation; (2) the stage of the development of fever; (3) the stage of the development of local symptoms; (4) the stage of crisis or defervescence; (5) the stage of convalescence.

1. The stage of incubation, which may also be called the stage of preliminary symptoms or the prodromal stage, extends from the first introduction of the specific poison, whatever it may be, whether a living germ, or an effluvium, into the system to the first manifestation or development of fever. This stage is characterised by malaise or a feeling of being not well, evidenced by "loss of appetite, lassitude, depression, stiffness, racking of the limbs, slight giddiness, earache, palpitation at times, also dull pains about the groins, the axillæ, &c., where buboes subsequently appear." Symptoms may be worse than even these. "The face of the patient is pale and listless, the features are distorted, the eyes dull and hollow, the look staring, speech is difficult, and walking stumbling, giving the impression of one heavily drunk." There may be nausea, often vomiting, generally constipation, at times diarrhoea, oppression of the chest, intense headache. The duration of this stage may last from a few hours to five, six, seven, or even ten days. After this stage comes on

2. The second stage, or the stage of the development of fever, which is ushered in by paroxysms of shivering simulating ague, for which it may and often is mistaken. The fever is marked by irregular exacerbations and remissions. The temperature may not be higher than 100, but generally varies from 102 to 105 or 107. The pulse becomes quick, ranging from 100 to 150, weak and irregular. The respiration becomes rapid and shallow, varying from 20 to 50. "The skin is hot, dry, non-perspiring, and attended with a peculiar earthy odor most marked in the general septicæmic cases." The face appears pale and collapsed, but more often somewhat swollen; the eyes are suffused, bright, but staring; the pupils mostly dilated; the hearing weakened. With the advent of the fever the symptoms of the first or prodromal stage, the lassitude, the nausea, the vomiting, the headache become worse. In addition there is pain and a sensation of heat as of burning charcoal, in the epigastrium, and at times a sensation likened to being stabbed in the breast. The thirst is said to be violent and constant. Dr. Dyson makes no mention of this in his Report of the plague in Bombay. The tongue presents a characteristic appearance,

and the experienced physician may take it as an early indication of the disease: the dorsum is thickly coated white as with chalk or mother of pearl, the edges and tip remaining clear or assuming a bright red appearance. Sometimes the tongue becomes actually swollen, and, being too large for the mouth, protrudes. Later it becomes dry, cracked, and covered with a dirty brownish coating. The lips, teeth, and even the nostrils are covered with sordes. The vertigo, headache, and drunken appearance of the prodromal stage become worse, and soon pass at once into stupor and coma or after delirium, restlessness, and jactitation of the limbs and tendons. When coma supervenes the patient has a dull, stupid apathetic look with generally half-shut and seldom completely shut eyes. Even when conscious, the patient is hardly able to answer a question, if he does, he does so slowly and partially, and falls back into stupor while answering. In this stage there is either constipation or diarrhoea. The diarrhoea, according to its character, may be a favorable or an unfavorable symptom. If it is mild, simply bilious, and not exhausting, it is a good sign. If the stools are dark, offensive, copious and exhausting, the diarrhoea will aggravate the prostration and hasten the fatal end. The urine is much diminished, often bloody and may even be suppressed.

3. The third stage, which has been, though not quite correctly, called the eruptive stage, is the one in which we have the development of local symptoms. These are buboes or inflammation and swelling of the lymphatic glands. They are observed in more than two-thirds of the cases. They are found in the groins, the armpits, on the edge of the lower jawbone and the neck, quite exceptionally at the elbows, in the bend of the knee or above the clavicle. And their frequency is in the order in which they are mentioned, that is, they are most frequently found on the groins, less in the armpits, lesser still on the edge of the lower jaw and in the neck, least of all in the other places. According to ROESSLE's statistics, in 2,700 cases of the plague inguinal buboes were present in 1,841, axillary buboes in 251 cases. Inguinal buboes occurred 175 times on both sides, 729 times on the right side, 589 times only on the left one. Axillary buboes occurred 9 times on both sides, 185 times on the right, 166 times on the left side. Maxillary buboes alone occurred only 130 times, and among these 67 times in children. CASIADIS in 1,826 cases found inguinal buboes in 720, axillary buboes in 406, cervical buboes in 98, buboes in several places at the same time in 122.

As a general rule, the eruptive stage follows the first manifestation of fever by one, two, three or rarely four days, that is, the buboes make their appearance on the second, third, fourth, or fifth day of the fever. These swellings are preceded by very acute pains of a stabbing character in the regions in which they are to appear. The enlarged glands are rarely numerous, as a rule one of a group is conspicuously enlarged. The size of the swellings varies; at the onset they are small, but soon become as large as a goose egg, and may even be as large as an orange, or larger. In the Bombay cases the number and size of the buboes afforded no indication of a favorable prognosis. Suppuration is generally looked upon as a favorable, flattening and unfavorable, sign.

* Reproduced from the Calcutta Journal of Medicine by request.

Along with buboes, boils and carbuncles may appear, but comparatively much less frequently. In Bombay the frequency was scarcely 1 per cent. In this eruptive stage in the majority of the cases the symptoms of the second continue with unabated intensity, and then become aggravated, terminating in death. Or they begin to abate and then comes the next stage.

4. The stage of crisis or defervescence follows the eruptive stage when, with the appearance of the buboes, the temperature begins to fall and perspiration sets in. The pulse becomes stronger and less frequent, falling to 100 or even 90. The patient becomes quieter if he was restless, more sensible if he was comatose. His expression becomes more natural. The tongue becomes moister and cleaner. The dilatation of the pupils becomes less, and the eyes less suffused. The urine becomes more and more copious. The buboes suppurate or in rare cases remain stationary for sometimes.

5. The stage of convalescence follows insensibly the stage of crisis. It is, indeed, the continuation of the latter with continued improvement in all the symptoms. "Convalescence," according to SCHUBERT, "sometimes proceeds pretty quickly; often, however, it takes a long time, particularly in the case of prolonged suppuration of the buboes, of suppurations of internal lymphatic glands, of carbuncles, parotitis, abscesses of the skin or deep-seated tissues, of pneumonia, or of a persistence of the typhoid condition." The earliest day at which convalescence may commence is the seventh, it generally commences from the tenth and it may not commence before the fourteenth day.

The stages above described are what are observed in the typical cases where recovery takes place. Very often considerable deviations occur from this typical course. Thus, the first stage may be so short as to be scarcely noticed, and the symptoms may be the gravest from the beginning. The patient is struck down at once with utter prostration, and he may die in the course of a few hours or at the latest within two days before the characteristic symptoms are manifested, that is, before the third stage is reached. There may not even be any marked second stage, that is, there may not be any febrile reaction at all, or if there is, it is quite out of proportion to the prostration. It is to these cases that the term *fulminant* or *foudroyant* has been very properly given. They are generally observed at the commencement, but also during the course and end of an epidemic. "The conclusion," says Dr. PAYNE, "that they were part of the prevailing epidemic—the infection having overwhelmed at once, as it were, the sufferers—appears justified by the prevalence, at the same time, of an intermediate class of cases, also very quickly ending in death, in which some traces of glandular swellings were observed, with profound disturbance of the nervous centres, convulsions or coma, and rapid formation of violaceous and purpuric spots."

These so-called intermediate cases should also be included in the fulminant class. The difference only is that the three first stages, though hurried one into the other so as to follow each other in rapid succession, are just distinguishable to show the character of the disease. Death takes place in the fulminant cases from within a few hours to within two days of the commencement of illness. In the cases just less severe than the fulminant

form, that is, when the early stages are clearly distinguishable, death takes place in the fulminant cases within four to seven days. The passing over the seventh day is looked upon as a favorable sign which promises recovery.

The order of the second and third stages may be reversed, so that the glandular swellings may occur first, and the fever come on after. These are generally, but not necessarily, mild cases. The febrile reaction after the appearance of the buboes may be very severe and lead to a fatal termination. Sometimes preceding and following an epidemic are observed cases unaccompanied with any fever, or with only such slight febrile disturbance as not to preclude the patient from going about his business. These are said to be cases of abortive or ambulatory plague, abortive because they do not develop into the full disease, ambulatory because the patients can walk about. These cases do not seem to carry infection.

Dr. WINTERBURN has very properly remarked that "it is one of the characteristics of this distemper that 'on the first breaking out the disease has never been known to be the plague.'" The foudroyant cases of plague so closely resemble similar cases of pernicious malarious fever that they cannot be distinguished. The abortive cases may be mistaken for non-venereal and even venereal buboes, and vice versa. "The glandular swellings and the carbuncles which are the significant evidences of this disorder, also occur in connection with the intermittent fevers of the same district; not to the same extent, nor with the same malignancy, but still sufficient to obscure diagnosis." Again, plague is very insidious in its first appearance. It never begins as the plague. Its forerunner often, though not always, is a constantly increasing sickness, and a tendency of all diseases to assume the malignant type.

The difficulty of diagnosis vanishes when the disease rages as an epidemic. "No other idiopathic fever," says CABIADIS, "attacking a multitude of persons at the same time, is characterized by glandular swellings, carbuncles, and by those severe manifestations of the nervous, sanguineous, and biliary systems which declare themselves in an attack of plague." During an epidemic the foudroyant and the abortive cases cannot be mistaken for any other disease. During an epidemic a patient may be known to be plague-stricken by his very physiognomy which is one of apathy and hebetude, and very seldom of anxiety and undefined fear. Such diagnosis, however, would be deceitful and dangerous at other than epidemic times.

What about the bacteriological diagnosis of plague? Our readers are familiar with the so-called grand discovery of the specific bacillus of plague by the Japanese bacteriologist KITASATO, independently and almost simultaneously corroborated by the French bacteriologist YERSIN. And notwithstanding the investigations made by Commissions of several Governments, notably of Germany and Egypt, and the investigations by HARKINS and HANKIN, we do not think the matter has been quite definitely settled yet. There is still so great a difference of opinion on the subject, as we pointed out in our last number, that it has led Professor CHOCKERHANK to believe that the real nature of the organism of plague is yet unknown. And only recently the Health Officer of Calcutta is reported to have said that even in undoubted

cases of plague, the bacteriological examination of the blood does not give positive results. Under these circumstances, to place absolute reliance upon bacteriological diagnosis would not be safe and may be, as we know to our cost, dangerous.

SOME PRACTICAL POST-MORTEM POINTS.*

By GEORGE W. COX, M.D.,

Chief Surgeon, Chicago and Texas Railroad; Member Illinois State Medical Society, and Examining Surgeon Bureau of Pensions, Murphysboro, Illinois, U.S.A.

1. Get all the anatomical knowledge you can out of every autopsy you make. It is, therefore, advisable, especially in the case of females, to perform a preliminary laparotomy. Many surgical operations can be practiced upon the body without disfigurement—such as Alexander's operation, removal of the appendix vermi formis, stretching of the sciatic nerve, etc.
2. Do not forget to dictate the post-mortem notes while the autopsy is in progress.
3. Respect the feelings of the friends in every possible manner, and always return everything in a private house to its proper place. Be sure to leave no bloodmarks behind.
4. Be sure you have the legal right to make the post-mortem before you begin. The nearest relative, or the one who is going to pay the expenses of the funeral, should give the consent in writing.
5. Do not take away more tissue from a post-mortem than you are able to thoroughly work up.
6. Try to encourage a demand among the laity for the performance of autopsies.
7. In making an autopsy, have a regular method for its performance, which is only to be modified by exceptional circumstances. Finish the examination of each organ in as thorough a manner as possible before the examination of another organ is commenced.
8. Label all your specimens at once with name of person from whom the specimen is removed, character of the specimen and relations in the body, date, and preservation fluid employed.
9. If you are so unfortunate as to cut yourself, wash the wound with running water for four or five minutes, and then dress antiseptically. Do not, out of bravado, go on with the post-mortem if there is anyone else present who can complete it.
10. If you are not making the autopsy yourself, do not be too forward in making suggestions to the one who is making it; but always be ready to do anything that you are asked to do in connection with the autopsy.
11. Let your medical friends enjoy the autopsy and specimens with you.
12. Get all the post mortems you can. Never refuse to make an autopsy for another when you possibly can.
13. Tact will get you many autopsies; curiosity of relatives and friends can often be worked upon to get permission for an autopsy.
14. As the object of the autopsy is usually to find out the cause of death, either for legal or scientific purposes,

the post-mortem should, therefore, be conducted in as thorough a manner as possible.

15. In legal cases, be sure to protect yourself in every way. The jars, which should never have been used, containing the specimens, should be sealed in the presence of a witness.

16. If you value your peace of mind, do not put yourself forward as an expert witness in medico-legal matters. Knowledge, which you already have, should be freely given to the court in criminal cases, but the court cannot compel you to obtain expert knowledge without your consent.

17. In Germany, the legal evidence of a post-mortem held by gaslight, has been judged by the court, except under certain peculiar circumstances, to be void.

18. If two persons are lifting a body, the lightest weight is at the feet.

19. Chloroform placed on a towel, and the head enveloped therein, will quickly dispose of pediculi capitis.

20. Many signs of inflammation, especially of the mucous membranes, disappear after death. Remember, red flannel often colors the skin red.

21. Make the undertaker your friend. Do not recommend an undertaker who disapproves of post-mortems.

22. It is a good knife that will keep its edge in more than one post-mortem.

23. Do not jump at conclusions too quickly. Tentative diagnoses alone should be made until the post-mortem is complete.

24. Always weigh the important organs, and have some method by which you can tell the right from the left organ in case of the double ones. One nick in the left sided organ, and two in the right will readily distinguish them.

25. Wash your hands frequently during the performance of an autopsy so as not to allow the blood to dry on the skin.

26. In opening a cystic kidney, be careful that the liquid does not injure the eyes nor soil the linen, as when the kidney is opened, the liquid in the cyst is under pressure, and may squirt several feet.

27. A duct can often be easily followed by making a nick in it and then introducing a grooved director in the direction you desire to dissect. This is especially useful in the ureters and the ductus choledochus communis.

28. In writing the account of an autopsy, describe what you see; do not use names of diseased conditions; these should be put in under the head of pathological diagnoses.

29. Wine or aromatic spirits of ammonia will best take off the odor from your hands. This odor is usually gotten from opening the intestines.

30. Ammonia will usually remove iodine stains. A weak solution of the hypobromite solution will remove carbol fuchsin and other aniline stains from the hands.

31. Any organ which you desire to save should be placed in a safe place, so that it will not be returned to the body and sewed up.

32. The dissecting room is a poor place to study pathology on account of the chloride of zinc forming with albumen an insoluble albuminate of zinc.

33. Nervous tissue for microscopical study should not be placed in zinc chloride or in alcohol.

* Reproduced from the Medical World by request.

34. Remember that a post-mortem, with the exception of the brain and cord, can be made with a pen knife.

35. Remember that the thoracic and abdominal organs can be removed by the rectum or the vagina.

36. Before removing the calvarium, have a basin so placed that it will receive the blood and cerebro-spinal fluid.

37. Drawings, photographs, casts, cultures of micro-organisms, and microscopic slides are valuable additions to a well written account of an autopsy.

38. A lesion in one part of the body will often suggest a careful search for a lesion in another part of the body.

39. Do not mistake the normal for the abnormal.

40. Squeezing the gall-bladder after the duodenum has been laid open, will often cause bile to pass out of the papilla; the ending of the common bile-duct can thus be demonstrated.

41. Remember that frozen sections of fresh tissue can be cut and mounted in a half hour to one hour.

42. Three hours is none too long in which to make a complete autopsy.

43. Be careful that the first rib does not scratch your hands when removing the tissues in that region; therefore cover over the cut ends of the clavicle and ribs with the skin flaps.

44. Blood makes a good glue for affixing labels, and the blood of a person dying from hydrocyanic poisoning makes a most excellent red ink, which will keep for years without the addition of any preservative fluid.

45. Remember that after the brain has been removed the fundus of the eyes can be removed by a circular incision posteriorly, without disfigurement. The inside should then be stuffed with dark colored wool or cloth.

46. In private cases, you will frequently be judged as to your skill as a pathologist by the neatness with which you sew up the body.

47. If you discover suspicious lesions, always stop the post-mortem and report the case at once to the coroner.

48. Remember, in warm weather, that the intestines are especially liable to undergo rapid decomposition when exposed to the air.

49. Remember that a railroad train or cart may pass over the body and there be no more abrasion in the skin than a brush burn.

50. Remember that the color of organs is frequently changed when exposed to the air by the oxidation of the hæmoglobin; also that the sulphide of iron frequently discolours organs after death, due to the sulphuretted hydrogen during decomposition precipitating the iron of the hæmoglobin.

51. The clavicle can be grasped and moved, and the claviculo sternal articulation thus readily discovered.

52. In removing the cord, the following method may be used without disfigurement to the skin of the back part of the neck. Make a circular incision from the middle of the trapezius muscle of the one side to the middle of the same muscle on the other side, using as the center of the circle the external occipital protuberance; this will take you in the median line to about the second dorsal vertebra; then dissect away the skin with the

muscle attached, and elevate the flap with a tenaculum and draw the shoulders backward; a sufficient amount of space will then be given to remove the cord in the usual manner.

53. If the rectus muscles on each side be cut near its origin, in the direction of Poupart's Ligament, the abdominal cavity will be much more thoroughly exposed to view than in the ordinary manner: first, however, examine with the finger for hernia.

54. And lastly, be honest. Everyone diagnoses lesions during life which are not found at the post-mortem. Even after a most careful post-mortem, it is often impossible to tell from what the patient died.

—:—:—

EMERGENCY OPERATIONS.*

By MOADAM ECOLES, M.D., M.S. (Lond.), F.R.C.S.E.
Assistant Surgeon to the London Hospital.

To the four classical surgical emergencies—(1) asphyxia, (2) hæmorrhage, (3) intestinal obstruction and (4) retention of urine—, a fifth—cerebral compression—must now be added. None of these brooks delay, and in all of them practically operation is indicated. As time will not permit entering into any of them exhaustively, only some salient points of each will be mentioned.

I. *Asphyxia*.—Any tube in the body may have its lumen obstructed by (1) compression from without, or by (2) obstruction from some substance within the tube, or by (3) some thickening of its own walls, chiefly due to new growths or inflammatory products. Pressure on the trachea (which is the tube, most commonly dealt with in surgical asphyxia) may be caused from without by a thyroid tumor, for instance, or it may be blocked by a pea or bean or other foreign body that has been inspired—in this latter case a bronchus is more frequently blocked than the trachea—or its lumen may be narrowed by its own walls being thickened by a deposit of membrane such as in diphtheria. Any part of the respiratory tract may be thus occluded and demand immediate removal of the cause of the obstruction. This may either be impossible or may consume too much time while the patient is dying for want of oxygen. Failing to get rid of the cause, we must overcome the effects of the blocking by making an artificial opening, if possible, below the site of the obstruction. This may be done by (1) high or (2) low tracheotomy, (3) laryngotomy, or (4) laryngo-tracheotomy. Though the last operation is most suitable for children, still the first has often to be performed in an emergency without adequate assistance or a plethora of instruments, and very likely in a house in which there is a great deal of confusion.

The instruments essential for high tracheotomy (*i.e.*, above the isthmus of the thyroid gland) are:—A sharp scalpel, a pair of dissecting forceps with a good spring, several pressure forceps for temporarily arresting bleeding, a pair of blunt hooks, a trachea dilator. All these should be scrupulously clean and sterilised just before use: so if there be a kettle on the fire in a sick room just drop your instruments into the kettle.

* A Post-Graduate Lecture Delivered at the West London Hospital and specially reported for the *Indian Medical Record*.

While your instruments are boiling, loosen the patient's clothing and wash his neck with soap and water and an antiseptic, if any be at hand. Spirits of wine is often in a house and is a good emergency antiseptic to use. Then wrapping a towel or a shawl round the upper part of the trunk, so that his arms may be bound to his body, place the patient on his back on a table in a good light—with his neck extended as far as possible and his chin and sternum in the same line; so that the structures in the middle line become tense and, possibly, the superficial veins slightly emptied.

If the patient is completely unconscious, no anæsthetic is needed; but if otherwise and neither cocaine nor cocaine be available, a little chloroform will help to overcome the spasm of the glottis. Now standing on the right side of the patient make an incision well up on the larynx in the middle line starting from the lower border of the thyroid cartilage and continuing it downwards for at least 1.5 inch. Never rest your elbow on the chest of the patient whose violent efforts at respiration will shake your elbow and spoil the operation which should be performed promptly and quickly, but studiously avoiding hurry and always keeping in the middle line unless the trachea has been pushed aside by a tumour when its true position must be made out and the trachea steadied with the left hand while the incision deepened through the subcutaneous tissue to expose the muscles, which must be carefully separated from each other in the middle line and all bleeding points seized with pressure forceps. Remember the venous bleeding, which is really due to engorgement of the right side of the heart by the respiratory obstruction, rapidly ceases when the trachea is opened. The deep cervical fascia lying across the upper part may cause a little trouble, but the best plan is to divide this fascia vertically and go right down through the isthmus of the thyroid gland, though in patients, exceeding 10 years of age, it is better to divide the deep cervical fascia transversely and drag it (and the isthmus of the thyroid gland) downwards. As soon as the whitish rings of the trachea are clearly seen and definitely felt, plunge the scalpel, with its cutting edge towards the chin, into the trachea in the middle line and incise upwards through the first two rings of the trachea and through the middle of the cricoid cartilage in infants. The trachea being opened and the edges of the wound held apart by the blunt hooks, clear out as much as possible of the obstructing membrane by picking it off with the dissecting forceps or by twisting it on to a feather moistened with bicarbonate of soda. Some suggest that the membrane should be sucked up. When the trachea has been sufficiently cleaned out, the tube may be placed in position and the wound treated antiseptically.

II.—*Hæmorrhage* demands prompt attention, no matter what its cause or origin. Leaving injuries, &c., aside for future consideration, let us confine ourselves to one of the means for overcoming loss of blood, whether from so-called rupture of a varicose vein or post-partum bleeding. To overcome the collapse produced by the diminished blood pressure, owing to the unfilled state of the vessels, the former practice was to (1) either directly transfuse the blood from one person into the veins of another, or (2) blood was taken from the giver into a bowl, then defib-

riated and poured into the veins of the receiver; but both these methods are open to serious objections and the grave risk of subsequent embolism.

It is now recognised that all that is needed is a fluid of such a nature as will not injure the blood of the receiver, and the details of the method are as follows:—The skin over one of the subcutaneous veins at the bend of the elbow or on the dorsum of the foot having been rapidly and thoroughly cleaned and the vein cut down on and divided transversely, a cannula (preferably of vulcanite) is passed into it and tied into position. To the cannula is attached some 2 feet or more of rubber tubing provided with a funnel and a clip to control the flow. Through this funnel is introduced by hydrostatic pressure from a height of about 18 inches sufficient warm water containing common table salt in the proportion of a teaspoonful to the pint, or a more elaborate fluid made by mixing sodium chloride grs. 30, potassium chloride grs. 3, sodium sulphate and carbonate an grs. 25, and sodium phosphate grs. 2 in 1 pint of boiled water. At least 30 ounces (sometimes several pints) of either of these fluids maintained at 100°F are transfused into the veins of the receiver as a temporary measure to increase the tension in the vessels and so enable the heart to continue its action until the patient is able to form fresh blood to fill the vessels. If the necessary apparatus is not available and the heart is still beating with fair strength, the fluid may be rapidly absorbed into the vessels and the blood pressure increased by injecting about half a pint of fluid into the rectum or the fluid may be introduced into the cellular tissue on the surface of the scapula.

III.—*Intestinal obstruction* is too large a subject to be dealt with here, but delay in treatment by operation is to be deprecated and herniotomy is certainly preferable to taxis in the majority of cases of strangulated hernia.

IV.—*Retention of urine* often causes very painful and dangerous distension of the bladder which is only partially covered with peritoneum on its upper and posterior part. The bladder may be entered, without injury to the peritoneum, through (1) the urethra, (2) just above the symphysis pubis, and (3) through the rectum below the reflection of peritoneum. The last method is open to several objections, and where entrance is impracticable per urethram, the bladder may be reached by supra-pubic aspiration, to do which first shave and wash the pubic region, after which make a small incision in the skin in the middle line just above the symphysis. Puncture the bladder through the incision with a fine trocar and cannula attached to the aspirator bottle. The puncture should be made downwards and backwards towards the tip of the coccyx and the amount of rarefaction in the bottle should be slight. Repeated aspiration does very little harm, provided a small trocar and cannula are used.

V.—*Cerebral compression* may be due to (1) depressed fracture, (2) extra-dural hæmorrhage or the presence of pus either (3) extra-dural or (4) intra-cerebral. Operation is imperative, as it is an emergency in which prompt operation may make all the difference between life and death, and in the majority of cases the operation consists of trephining and removing the cause of the compression.

HYGIENIC AND MEDICAL ASPECTS OF A TYPICAL NATIVE SCHOOL IN INDIA.

BY JOSEPH BENJAMIN BAMBOLKAR, C.M.S.

Medical Practitioner, Ahmedabad.

ON the 5th March 1898, Drs. N. D. CHAKRAPATI and C. H. DESAI were deputed to accompany me and report on the health, and other conditions of the Ahmedabad Khadia Municipal Vernacular School, which occupies three rented buildings in a very crowded portion of the city. The subjoined is an account of the main building, the lower floor of which is occupied by 28 boys of the VI Standard. This school-room, which opens to the south only—the other sides being shut in by houses with a narrow street separating them—is 24 feet long by 16 broad, and has a sloping roof, which is 102 inches at its highest and 70 inches at its lowest height from the ground and is devoid of ceiling.

The area of the room was 384 feet and its cubic capacity 2,688 cubic feet; thus allowing 10 square or 72 cubic feet per pupil, which is 5 and 78 feet respectively below the minimum laid down by NEWSCOLMS.

Five east and two north windows, each measuring 64 by 27 inches and a south door 73 by 33 inches furnished light and ventilation to the pupils, who had to squat on the floor; for desks or benches there were none, and the total furniture of the room consisted of a table, a chair, a black board, a gong, 8 maps and a box for records.

Four of the pupils were Mahomedans, while the remainder, who were Hindus, may be further classified—6 Avdich Sapara; 2 Travadi Mewada, 2 Modh Chachurvedi, 1 Bhat Mewada, 1 Shrigod, 1 Visnagra Nagar, Sachora (i.e., 14 Brahmins of sects), 3 Banias, 4 Kunbis, 1 Tamboli, 1 Gola and 1 Koli.

As neither steelyards nor weighing machine were available, we could not add the weights of the boys to the following information concerning them, according to their several ages:—

	8	2	...	3	2	5	3	1	...	16
	9	...	2	1	...	1	...	1	...	5
	10	1	1

Briefly stated for comparative purposes the averages per pupil according to age were:—

Ages.	12	13	14	15	16	17	18	19	Total.
Height shown in inches	51½	51½	56	56½	59	63	64½	62½	58
Number of inches round chest	23½	22½	24	24½	26½	27½	26½	26½	25½
Pulse beats per minute	98	84	97	93	92	90	78	92	91
Respirations per minute	31	33	32	27	32	32	18	20	24
Number of teeth	24	26	27	29	28	28	29	28	28
Hours of sleep indulged in	8	8½	8½	7½	8	7½	7½	9	8

From which tables it is plainly evident that the physique of Indian school boys is considerably below that of American and European lads of similar ages; but this is due partly to the want of proper physical training and partly—rather chiefly—to insufficient feeding or poor quality of food. Thus while 5 of the lads had a mixed diet, 23 had to live exclusively on vegetable food, and took but two meals a day, while the parents of two only of these boys could afford to give them a little milk every morning. The staple food of 14 of these 28 boys was wheat, 6 used *bajri*, and 8 ate both wheat and *bajri*, but all of them had rice occasionally.

Vision was good in 23, fair in 2, and somewhat myopic in 3 of these boys of whom 22 kept good health, 2 suffered from chronic granular ophthalmia, 3 kept fairly well and 1 had indifferent health.

Exercises.—The school being devoid of compound or play ground, the boys, had to indulge in their romping and games at home, and the want of this physical exercise was manifested by their flat chests and undeveloped muscles. The numerators of the following fractions shows the hours devoted to play and the denominators the number of boys who indulged in such pastimes: $\frac{0}{4}, \frac{0.5}{6}, \frac{1}{7}, \frac{1.5}{4}, \frac{2}{7}, \frac{3}{1}$. So that the average was $\frac{19}{23}$ play, 8 hours sleep, and something like 14 hours of school and private study. This is harmful and totally disproportionate. There should be a between-study interval.

to teach the boys physical drill, dumb-bell, swinging and such like manly and healthful exercises.

The pulse, though accelerated in some of the boys, was not near as strong as it should have been, and both heart-beats and respirations were hurried; but this should rather be attributed to their excited state of mind and the flatness of their chests than to disease.

Vaccination.—Twenty-two had been protected by vaccination, 5 had had small-pox, and of these 2 had also been vaccinated, while a nagar boy, aged 17, had not been vaccinated.

Bathing, &c.—Ahmedabad being supplied with tap-water, the boys get pure water for potation and ablution, but while 2 of the Mahomedan lads bathed once a week only, 1 of them bathed every fourth day and 1 every second day; whereas of the Hindu lads 2 bathed *twice* daily, 21 once a day, and 1 every two days. Of all these lads 6 favored cold baths while the remainder used warm water, and it was noticed that the cold water bathers were more robust and enjoyed better health than the others.

Civil Status.—Of these pupils 12 paid full tuition fees, 4 paid half fees, and 12 were unable to pay anything were admitted "free" of charges; 8 of them had parents who were fairly well off, 5 were in medium circumstances, and the remainder very poor. The avocations of the parents were as follows: 8 goomastas or agents or salesmen, 3 weavers, 2 educational, 2 mill hands, 2 astrologers, 1 in railway service, 1 money-lender, 2 petty traders, 1 native doctor, 1 Government pensioner, 4 professional beggars and 1 no occupation; but while 18 of these lads had both parents living, 3 had lost their fathers, 5 their mothers, and 2 were orphans.

All things considered, the boys were far more healthy than might be expected. None of them had curvature of the spine or any sort of cutaneous affection, and only one lad, who was the most puny of them all, had a wry neck and chronic pleuritic effusion in his right chest. The remainder were sound.

The "type" in which the text-books were printed was too small and rather trying for the eyes. There being no proper latrine accommodation, the boys micturated wherever they got the opportunity, and it does certainly seem strange that a large and important school like this (it has 600 boys, but we had not the time to crucially examine all of them as we did the 28 this report includes) should be without efficient periodical medical inspection, and that no arrangements exist for the rapid and definite distinction of contagious affections should any appear at this school, and the sooner the municipality remedies this serious omission, the better for the township and for the boys who would otherwise be unwisely and unkindly exposed to the risk of infection.

ARREST OF HÆMORRHAGE IN HÆMOPHILIA.

HAVING failed to arrest bleeding from a small facial wound by perchloride of iron, Dr. BRUNWALD aspirated some blood from a healthy subject and deposited it on the wound which stopped bleeding as soon the added blood coagulated. His explanation that this remedy acts by supplying the ferment necessary for thrombosis in the small vessels is pretty well supported by the success obtained by Dr. A. E. WRIGHT (*Proc. Med. Soc.*) with solutions of fibrin ferment and of calcium chloride as styptics. —*La Sem. Med.*

A MIRROR OF PRACTICE.

TWO CASES OF FILARIAL DISEASE.*

By SURGEON-CAPTAIN F. J. CRAWFORD, I. M. S.
General Hospital, Madras.

CASE I.—A man went to the Madras General Hospital, on 14th March 1897, suffering from filarial disease, the trouble for which he sought relief being periodical attacks of pain and swelling in both groins, with swelling of the "testicles" and fever. From his own account it was evident that the attacks, which were becoming more severe and frequent, were making life a burden to him. The sense of heaviness and uneasiness, the irritation of the pelvic and genital organs, the consequent fits of nervous depression and the melancholy state of mind caused by inability to carry out his marital duties were graphically described in a letter written by him while he was waiting his turn for operation in the hospital. He said that if he could not obtain relief he would end his life, and his appearance and general demeanour tallied well with this statement. He was troubled with nocturnal emissions, and though quite a young married man, the well-known mental depression which characterises such cases was well marked in him. On examination there was discovered on the right side a hydrocele which was not of the ordinary kind, but quite soft and flabby, the skin as well being slightly thickened. Both groins were the seats of swellings which consisted of several distinct glandular enlargements and enlarged lymphatic vessels, giving to the touch the characteristic boggy feeling, gradually subsiding to some extent on firm pressure. The affection had lasted for some years and the swellings had gradually become more marked. Exacerbations occurred every month or so, at which times the local trouble increased, and on these occasions the patient's mental condition, according to his own account, was one of great despondency and anxiety about himself. He made no secret of the almost uncontrollable impulse which he had during the attacks to put an end to his life. The hydrocele was first operated on and after letting out the pinkish milky fluid the tunica vaginalis was freely removed. The affection, in fact, was treated in exactly the same manner as an ordinary hydrocele. Healing readily took place and the patient remained in hospital, because subsequently to healing his groins felt heavy and swollen when he was standing. The operation on the hydrocele was performed on 17th March and on 14th April, after he had been completely cured of the hydrocele, the left groin was operated on, as it presented more urgent symptoms than the other. Two enlarged glands were removed from the inguinal region and they presented on dissection small cavities containing milky fluid, one large gland, which was like a horseshoe in shape, curling behind the vessels on the inner side and having a large portion posterior to them. Several lymphatic vessels, which were much enlarged, were cut during the operation but they gave no trouble after being caught with artery forceps. The wound healed within a week by first intention and on the 21st the right groin was cleared out. This gave more trouble owing to the number and large size of the lymphatic vessels, the

* Reproduced from *The Lancet* by request.

field of operation being observed by the exudant of milky fluid which exuded, notwithstanding the efforts to tie the vessels. The cavity quickly refilled each time it was swabbed out and required packing with eucalyptus gauze before being dressed. This gauze was removed on the next day and the subsequent healing took place readily under a firm antiseptic dressing; the limb was kept in the flexed position for a few days. There was no swelling of the limb itself due to the lymphatic obstruction either before or after the operation. This very interesting case was rendered of further interest by the subsequent history. The patient left the hospital with the operation, incisions completely healed and remained with friends in Madras for a couple of weeks before returning to his native place. About ten days after leaving the hospital he returned to say that he had just had a slight attack, but this time the skin of the scrotum had become thick and heavy without either of the groins giving him trouble, and without any implication of what he called the "testicle," alluding, of course, to the tunica vaginalis, which was the seat of trouble during his former attacks. This fact pointed to the existence of lymphatic obstruction in the neighbourhood without actual enlargement sufficient to show on the surface of the body. The emissions, which were so harassing, no longer occurred, and he stated that he was "quite a new man." He will probably return to the hospital some day with a lymph scrotum and a further operation will be necessary. Taking the case, however, as a whole, no one will doubt the propriety of the different operation performed and their success in affording relief.

CASE II.—The patient was a Eurasian, who was admitted to the hospital for a troublesome swelling in the right groin in the region of Scarpa's triangle. It was the seat of periodical enlargement accompanied by fever and uneasiness. The disease had lasted for many years and was limited to this region. No symptoms pointed to the involvement of other lymphatic vessels. A longitudinal incision exposed a mass of lymph tissue which was composed of several moderately enlarged glands and dilated vessels. Owing of lymph was free during the removal, and it was found to be impossible to secure all the discharging points. The upper half of the incision was therefore stitched and the cavity was firmly packed with antiseptic lint. Several ounces of lymph must have been lost. Healing, though delayed by the fact that the wound was obliged to be kept open, was complete and uneventful. The oozing of the lymph ceased on the third day and did not recur, and the patient left the hospital with his local trouble quite cured. On examining the removed mass a probe could readily be passed along the dilated vessels, which were seen to anastomose freely. No filariae, however, were detected in the tumour.

Remarks.—Some interest has been excited by a paper read recently before the Bombay Medical and Physical Society on filarial disease. This disease is common in Southern India, and the Madras General Hospital is seldom without a case in its surgical wards which is either being operated on or awaiting operation. After long trial we have arrived at fairly definite rules to guide us in the treatment of this affection by operation. The disease, which is known as filariasis,

cannot now be looked upon as being of purely a local character in any instance. When a patient is attacked by the parasite, he probably remains a victim as long as he lives. The question of operation therefore resolves itself into the treatment of the different local troubles and inconveniences arising from the blocking up of the lymphatic system in different parts of the body. Many of these local troubles are subjected to operation with very decided success, so much so that there is neither doubt nor hesitation on the surgeon's part, provided that the general condition is satisfactory—in fact, the ordinary limitations attending all surgical procedures which are undertaken where life itself is not in the balance. I need only mention lymph scrotum, filarial hydrocele, and abscesses occurring in the course of lymphatic vessels where dead parent worms lie embedded. Though the system may still contain numbers of the parasites, there is no doubt regarding the utility of the procedure and the relief obtained. In these cases, though the disease is the result of interference with the flow of lymph, the glands and the main lymphatic vessels themselves are not found to exhibit symptoms. In another class of patients the blocking of the lymphatic system in a part shows itself in dilatation of the lymphatic trunks, which contain a pinkish milky fluid and have thickened walls. These dilatations occur usually in the neighbourhood of glands, and on careful dissection enlarged lymph vessels may be seen passing into and others passing from them to other dilatations or to the glands close by. Accompanying these are enlarged glands due either to thickening of their tissue and proliferation of the numerous lymphoid cells they contain or to enlargement of the lymph spaces in their structure. The groin is commonly affected, both the femoral and inguinal regions participating in the trouble and frequently on both sides. It is extremely probable in these cases that the pelvic and other internal lymphatics are also enlarged, especially where the affection is symmetrical, and at first sight it would appear that removal of the groin glands would give only temporary relief of the symptoms and be followed in a very short time by a return of the local trouble in its former severity. Surgical interference, however, yields more favorable results than this. That treatment is urgently needed in many cases is seen by the number of patients who come to our wards and by the severity of the local symptoms. One of the cases related above is a good example of this. As swelling occurs at periodical intervals, the sense of weight and fulness increases, pain, weariness and lassitude are complained of, with reflex irritation of all the pelvic organs, rendering the patient's life a misery to him. The fever, too, is severe and quite incapacitates him in his work, sometimes each attack lasting as long as ten days. A successful operation means much to the patient, and while it cannot be said to cure the general disease, it takes away completely his local trouble. It must be remembered, too, that these local manifestations take years to develop. The surgeon in India is, of course, confronted with the difficulty of tracing the subsequent histories of many of his patients and this may detract from the value of individual accounts of cases; but so far as it has been possible, to trace them patients are quite satisfied with the treatment and its subsequent result. Local recurrence, too, is practically unknown.

The wounds caused by complete removal of filarial glandular enlargement and lymphangiectasis have always been looked upon here as in no way differing from ordinary surgical wounds, and no case so far has occurred to induce us to look upon them in any other way. Careful dissection is naturally required, but owing to the small area involved, one pair of hands suffice to carry out the necessary steps of the operation and external contamination is reduced to a minimum. For this reason we look upon these cases as peculiarly suited to operative measures. Considering the comparative simplicity of the measures and their results as detailed above, I would not have thought it necessary to write on this form of local consequences of filarial disease had not very different results been obtained in Bombay following these operations. I am not aware that any elaborate statistics have been compiled on this individual subject, but the fact is we in Madras have not thought it necessary. We have looked upon all local filarial manifestations as being subject to ordinary surgical considerations when the question of operation was suggested by the arrival of a patient exhibiting them.

—o:—

CASE OF HYDATIDIFORM DEGENERATION OF THE PLACENTA.

BY RATAN SHAW T. NARIMAN, M.D., F.R.C.P., F.R.C.S.
*Honorary Surgeon to the Parsi Lying-in Hospital,
Bombay.*

A PARSİ multipara, aged 26, and in the eighth month of her tenth pregnancy, had "flooding" for nearly five hours before I was called in to see her. On my arrival, I found her somewhat collapsed, cold extremities and very feeble pulse, while a dirty cloth pad saturated with blood was tightly pressed into her vagina. I immediately gave her some hot milk with brandy in it to stimulate her. Enquiry elicited that she was 11 years married and had already had 9 children, of whom 8 died in infancy. She had had no miscarriages, and her "period," which was pretty regular, re-appeared four months after the birth of her last child and then stopped for two months, when the flow re-appeared and lasted for 24 hours only. Since then up to date (10th January 1898), she had "flooded" some seven times, and had obtained relief at a charitable dispensary.

Though she presented the physical signs of advanced pregnancy, the uterus was smaller than the calculated period of gestation demanded, and a loud uterine souffle was heard, but the sound of the foetal heart could not be distinguished, nor did bimanual palpation of the enlarged and elastic feeling lower the abdomen reveal anything like a foetal shape.

As the patient was very low, I determined to immediately evacuate the contents of her uterus, but on passing my index and middle finger into the vagina, I felt something like large blood clots, which I removed and found to be a bunch of hydatids connected to each other by slender pedicles.

The os being sufficiently dilated to admit three fingers easily, its contents were evacuated with finger and curette, and though there was actual evidence of conception having occurred and gestation proceeded far a space, not a vestige of the embryo could be found. Its inner surface

having been thoroughly curried, the uterus was freely irrigated with very hot carbolic water. The pains and hæmorrhage immediately ceased and the uterus contracted firmly, but as the patient was very low and feeling chilly, she was given a hypodermic injection of ether and strychnine and hot bottles applied to her extremities.

The patient passed a quiet night, but next morning her temperature and pulse rising to 102°F and 140 per minute respectively, re-irrigation of the uterus brought away a small quantity of debris, after which she was prescribed a mixture of Quinine, Ergot, Strychnine and Digitalis, under which her temperature came down to 99.8°F and pulse to 116 by the evening, and on the third day she was perfectly free from febrile symptoms, though her condition was still very low; but contrary to all expectations, she made an uninterrupted though rather slow recovery.

Examination of the evacuated contents of the uterus showed degenerated blood clots intermingled with placental remains and hundreds of pedunculated cysts, varying in size from tiny hempeeds to as large as almonds, but each containing a clear jelly-like fluid, and all cleaning pointing to hydatidiform degeneration of the placenta with early death and complete disintegration and disappearance of the embryo.

THIRD HEAD PRESENTATION WITH IMPACTION AT BRIM: UTERINE INERTIA, SYMPHYSEOT- OMY: FORCEPS DELIVERY: RUPTURE OF CERVIX AND PERINÆUM: RECOVERY.

BY ASSISTANT SURGEON T. M. SHAH, L.M.S.
Junagadh State Hospital.

On 3rd March 1898, a full term primipara, G. H.—, aged 30, was brought to hospital in an exhausted condition. Labor pains, which had set in 48 hours previously, had ceased entirely since morning, though the membranes had ruptured and the os remained partially dilated.

Vaginal examination disclosed a thin tough membranous and irritable os with the foetal head impacted in the brim, with the face looking forward and towards the left obliquate foramen. The foetal heart was audible; but the uterus, which was exhausted, had contracted and the waters run out.

The bowels having been partially evacuated by clyster and a few ounces of highly colored urine withdrawn by catheter, the symphysis pubis had to be subcutaneously divided by bistoury, introduced from just above the clitoris, to get more room at the brim. Repeated intermittent forcible traction with the long axis forceps succeeded in removing a full grown still-born male child; but the difficulty of delivery being enhanced by the foetal face looking forward and refusing to be turned towards the sacrum, the right side of the cervix was incised and the perineum gave way during the extraction. Efforts to resuscitate the child proved futile, and as the uterine inertia was complete, the placenta had to be drawn out.

After evacuation of its contents the uterus contracted firmly and the perineal bleeding was checked by pressure.

The following day iodoform and carbolic oil were applied to the tears after douching with Condy's fluid, and the patient did exceedingly well till evening, when her

temperature rose to 100°F. and she complained of pain and swelling over the pubis, hypogastrium and in her thighs. By next day the pubic swelling was less, but the pain continued, and she was unable to move her lower limbs; while her temperature rose to 108°F., her pulse to 120, she vomited twice and complained of spasms and insomnia for which she was given quinine, chloral and bromide, while the antiseptic douches and fomentations were continued and diaphoretic mixture given during pyrexia.

The pains and swellings subsided by the ninth day; the patient began to improve steadily, and in the course of a fortnight regained the use of her lower limbs, whose temporary paralysis was probably due to continued pressure on the sacral nerves by the labor being delayed by uterine inertia taking place in a patient whose first conception occurred at a period of life when the passages were not sufficiently yielding to secure speedy or easy delivery of a large-sized full term foetus.

—:O:—

A CASE OF SNAKE-BITE: QUICK RECOVERY.

By ASSISTANT SURGEON GHULAM ALI, L.M.S.

In medical charge, Imperial Service Troops Hospital, Patiala State.

RAM CHANDAN, *et. 25*, a grass-cutter belonging to the Rajender Lancers, had barely left the cavalry lines at 6 A.M. on 20th June 1898, when he was bitten on the left heel—just above the posterior bulging of the os calcis—by a fairly large-sized Echis Carnata (the *karundia* of the Punjab or Uffia of Persia) that lay concealed in the grass.

The snake was promptly captured and its victim hurried by his comrades to the State Hospital, where I saw him, at 8-25 A.M., with his body bathed in a cold sweat, his feeble pulse was 52, and his labored respiration 21 per minute. He was in an extremely exhausted and sinking condition, while he lay on his back with half-closed eyes, whose corneae were moderately congested and their pupils fixed and slightly dilated.

I applied a Reliance tourniquet tightly round the leg, a little above the ankle joint, but as a fire was not just then available wherewith to cauterise the wounds, which were bleeding somewhat and as the tissues immediately under the higher of the two punctures was deeply ecchymosed, I carried an incision to a little to the outside of either bite down to the tendo achilles and completely removed the integument and soft tissues involved in the bites, rubbed the new wound freely with potassium permanganate crystals, after which I injected 1/40th grain of strychnine nitrate, in aqueous solution, into the skin over his cardiac region as well as gave him a draught containing brandy ʒj and liquor ammon. acet. ʒij.

The strychnine injection was repeated 15 minutes later, but the tourniquet was kept *in situ*. A fire being procured later on, the wound was seared to charring with live charcoal and the skin on either side of it subcutaneously injected with 2 grains of permanganate of potash.

To maintain his strength the patient was fed with food milk, which he vomited up at 7-30 A.M.; 15 minutes later a third injection of 1/40 grain strychnine nitrate was given and repeated at 10 A.M. and 1 P.M., making a total of 1/8 grain of strychnine.

As the patient complained of pain and discomfort in the foot, which had become cold and swollen and his toes blue by the stagnation of blood brought about by the ligature, the tourniquet was released at 8-30 A.M., when he was ordered brandy ʒiv, Liq. Ammon. Acet. ʒij, and Aqua Cajputi ʒi every three hours (*four doses only*) and fed on food milk till 6 P.M., when the pupils becoming normal, the congestion of the conjunctivae disappeared and the pulse rose to 78 and the temperature to 100-6°F.

By next morning the patient had quite recovered from the effects of snake-bite, and is now under treatment for the surgical wound made on his leg.

—:O:—

EPILEPSIA GRAVIOR: ITS TREATMENT AND CURE.

By ASHUTOSH BANDROPADHIA, V.L.M.S.,

In medical charge, Babu Bachu Lal's Charitable

Dispensary, Entally, Suburban Calcutta.

SHIBOO, a well built, stout, strong Hindu male, *et. 48*, who had for the past three years been subject to epileptic fits which recurred at intervals of two to three months and were usually preceded by severe headache, was, on 23rd January 1898, brought for treatment to this dispensary, where in my presence one of his attacks seized him. He foamed at the mouth and his tongue protruding through his clenched teeth was so severely bitten that it bled profusely. His eyes were open but the eyeballs rolled fearfully in all directions, while his pupils were widely dilated and his head was slightly turned towards his shoulder and fixed in that position. Pulse feeble but regular. He urinated involuntarily in a fairly broad stream. The fit lasted for fully 25 minutes, during which the rigidity of the muscles was of atonic character.

There was no history of heredity or syphilis, and the patient said that immediately before a fit he felt a sensation of chilliness rising up from the middle toe of his left foot—*Aura Epileptica*, probably—so I put him on

R Quinine Sulph.	grs. vi.
Acid Nit. Mur. Dil	ʒj xv.
Tinct. Belladon	3 j.
Pot. Bromid	grs. xxx.
Lq. Arsenic	ʒj xv.
Aqua Camph.	...	ad	ʒvj.
Ft. mist. ʒi t. d.			

and advised him to apply equal parts of glycerine and almond oil to the anterior fontanelles before and after bathing.

During the next eleven days he had but two attacks, which were less severe, and on the thirteenth day I gave him an iron ring which tightly fitted the middle toe from which the *Aura Epileptica* rose.

On the seventeenth day the man had a rather mild attack, but as the *Aura Epileptica* had shifted to the second toe, I ringed that toe also and the patient did well till the twentieth day, when he had a very mild attack and complained that the *Aura Epileptica* had travelled to his great toe: so I ordered all the toes of both feet to be ringed. From that day to the present time (June 1898) he has had no fits and the medicine was reduced to twice daily till the 5th March, when he was discharged cured.

THE Indian Medical Record.

16th July 1898.

ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA.

II.

ENTERIC FEVER.

THE RESULTS OF THE EXPERIMENTS ON BOILING THE WATER AND ADDING PERMANGANATE OF POTASSIUM.

IN the course of his remarks on the "Principal Diseases," the Sanitary Commissioner says, page 23 of the Report under review:—"In the matter of enteric fever the differentiation of the bacillus and the treatment of the disease by enteric serum, the diagnosis of the fever by the patient's serum-reaction to a true cultivation of the specific bacillus, preventive inoculation or vaccination, and the question as to how wide may be the dissemination of the enteric bacillus in nature, continue to be the chief topics of interest."

After this preamble, it is disappointing to find, on further perusal, that there is absolutely no evidence whatever of even the smallest amount of interest having been taken in any of these topics, as far at least as is shown by any light having been thrown upon them by workers in India.

It is quite possible that readers of the Report, not versed in the conditions which prevail in India, might be misled, by the above quotation, into imagining that the topics referred to had a living and practical interest in this country; this is not the case, the interest to which the Sanitary Commissioner alludes is altogether a parasitic one, nourished by the fruit of other's labor, and having no healthy independent growth of its own.

Owing to the dearth of any information to be derived from Indian experience, the Sanitary Commissioner is forced to go to European authorities for all the recent developments in the study of enteric fever, and he is kind enough to furnish us with a brief summary under the headings, Water; Air; Dust; Hardiness; Bread; Mouth; Raw Vegetables; Contagion; Sewer gas; Soil; Varying Virulence; Indians Abroad; Urine; Blood, etc. It is questionable, however, if the little attempt to enlighten us, which custom has somewhat staled, is successful.

From this congeries of facts borrowed haphazard up and down the medical journals of Europe, we gladly turn to page 27, where we find that "great use has been made in India during 1896 of boiling, and of the addition of potassium permanganate, alum, etc., for the purification of drinking water."

Here then at last we have some gleanings from the large field of Indian experience to which we turn, with not unnatural eagerness, expectant of some tangible results.

In this expectation we are not disappointed, for the results are there, tangible enough and fairly obvious; yet it is a curious thing that their real meaning appears to have hitherto escaped notice.

This is readily explained by the fact that they are not exactly what was expected; very much the reverse indeed; they are far from coming up to the Sanitary Commissioner's expectations; for he says:—"Not only are the reports of medical officers somewhat disappointing, but the reduction in the admission rate of India for enteric fever was only 0·8 per 1,000 of strength, 75 cases fewer." Further, he says, there is nothing to show "why the Punjab Command should have had a great reduction, the Bombay and Madras Commands a great increase, and the Bengal Command the slightest possible decrease."

He gives the following figures as the number of admission per 1,000 for enteric fever in each of the Commands for the two years 1895 and 1896:—

			Admissions per 1,000.	
			1895.	1896.
Bengal	80·8	80·2
Punjab	39·0	25·9
Madras	12·7	16·8
Bombay	16·8	25·5

It is evident then, from his point of view, that the experiment has been unsuccessful, perhaps even worse than unsuccessful; for according to him the results are inexplicable; that an official of the importance of the Sanitary Commissioner should be puzzled in this way is of course very wrong, and we can trace a very natural vein of annoyance in his reference to the disappointing nature of the medical officers' reports.

These medical officers evidently did not play the game, and the results would not work out to suit pre-conceived ideas, and the whole thing was most annoying to a poor bewildered Sanitary Commissioner.

And so the Government of India would appear to have drawn another blank, one more added to an already overgrown series, in their sanitary lotteries.

We don't exactly know how these little adventures into the realms of sanitation or etiology, to which we apply the term sanitary lotteries, come about, but we have our own ideas on the subject, to which the reader is welcome.

Some gentleman, we will imagine, has a fad, many of course have fads, and we have reason to believe that in India, this form of insanity is more rampant than elsewhere, for the excellent reasons either that no means exist for putting impractical ideas to the test of experiment, that the gentle warmth of the climate renders the proceeding too irksome, that it is too troublesome, or finally, that it is not worth while.

Now most of these fads are quite harmless, but the imaginary gentleman, to whom we have alluded, has influence, he has a position, he is very high up the official ladder in his own particular branch; therefore, he can make himself heard with good effect.

His particular fad finds favor with those whose daily routine it is to issue orders; it is cheap, a great recommendation; further, it gives no trouble to any one at head-quarters, it merely inflicts a considerable amount of irksome work upon sundry subordinates grilling in the plains, and augments the number of aggravating reports they are called upon to make.

These are all excellent qualities in a *dog*, and are quite sufficient to get it accepted.

If the idea is successful, its author gets the credit of being far sighted and energetic, and perhaps something more substantial, while the Government is pleased at having shown itself up-to-date in scientific research, without any undue expenditure. If, on the other hand, it fails—well, no harm is done—it only makes the subordinates a little more dissatisfied and gives them an extra grumble about the unprofitable nature of the extra work that is thrust upon them, increases their disgust with reports in general, aggravates the tendency to *conspicuous* work, and adds an iota to the general feelings of contempt with which it is their custom to survey the proceedings of their rulers.

The Government plunge a little too much in these matters, and moreover plunge in the worst possible way; they are ill-advised, they know but one or two horses in the race; yet they think it good enough to put all this money (metaphorically of course) on them. When they do not win, bewilderment results.

Now it is very possible that boiled water is a good horse in the enteric fever stakes, but of permanganate of potassium we know nothing, and should have expected less, from what we have heard of its other performances.

The Government backed them, and they have both failed to win. Our Sanitary Commissioner does not know what to make of it, but let him not be despondent, the results are not so barren after all, if he will but bring himself to look upon them in the right way.

Few, we think, will dissent from the proposition that, if enteric fever were a fixed factor, not liable to fluctuations and variations, and if it were an established fact based upon sound and reliable data that the disease was usually caused by the ordinary water supply, then we might confidently anticipate that a marked alteration in the incidence of the disease would follow upon a vital change in the character of the water supply.

The conditions of the proposition were however not fulfilled. Enteric fever varies considerably from year to year under the influence of conditions which are either imperfectly understood, or are not understood at all; and the result of the experiment we are discussing is to show that the influence exerted upon it by the ordinary water supply is so slight, that the vital change brought about in its condition produced no results that could be detected, amidst the other unknown quantities by which the incidence of the disease is controlled.

The fact is that the experiments carried out on the theory that the water supply was the chief cause of the enteric fever, proved as conclusively as possible that the theory itself was in fault, and that the influence of the ordinary drinking water upon the causation of enteric fever in India is either very small, or nil, and that all the trouble of boiling the water and adding permanganate of potassium was merely a wild goose chase.

Now this has not been noticed before, and it has entirely escaped the attention of the Sanitary Commissioner, as all side effects invariably do escape the observer whose attention is concentrated on a single point, or issue. This conclusion is however none the less obvious,

none the less clear, none the less irrefutable, and none the less important; and if it were only grasped, the experiment would not be so barren of results after all.

A very few figures will make this plain to anyone. We have seen that, according to the Sanitary Commissioner's figures, boiling the water and adding permanganate of potassium was followed by a large increase of enteric fever in the Madras and Bombay Commands, truly a most untoward result! So startling in fact, that the Sanitary Commissioner was quite unable to face it; there is no way of avoiding it; no means of explaining it away.

It stands out so clearly and strikingly that we will not further notice it except to remark, that it is difficult, if not impossible, to believe that such could have been the case, had the drinking water really been the factor in fault—otherwise the sooner the drinking water is let alone the better.

Some comfort is, however, reaped from the fact that, in the whole of India, there was a decrease of 8.0 admissions per 1,000 equivalent to 75 cases, and that in the Punjab there was actually the large decrease of 13.1 admissions per 1,000 of strength. How is this large decrease to be accounted for?

It is only too evident from his remarks, that the Sanitary Commissioner accepts this large reduction as the measure of the benefit to be derived from the adopted treatment of the drinking water; he says, "and no difference in the carrying out of the prophylaxis, such as earlier beginning or greater care can be made out from the reports as a reason why the Punjab should have a great reduction, the Bombay and Madras Commands a great increase, and the Bengal Command the slightest possible decrease."

From this sentence we conclude that the Sanitary Commissioner took up the position, that the Punjab decrease was due to the treatment of the water, and exhausted his ingenuity, without success, in endeavouring to discover some flaw or difference in the way the experiments had been made in Madras and Bombay to account for the strange discrepancy. Failing this he has to fall back on a querulous complaint of the disappointing character of the medical officer's reports.

Let us now tackle the Sanitary Commissioner by the evidence of his own figures and see if there are any grounds for attributing the Punjab decrease to the vital change in the water supply in 1896.

The Sanitary Commissioner is content in making his comparison to take the two years 1895 and 1896—this happy-go-lucky method of dealing with figures does not however satisfy us; it is always a dangerous thing to compare isolated facts of this kind, and by doing so this official has fallen into a very pretty trap.

In making a comparison of this kind nothing but a series of years can give information of any value.

Now in the following table will be found the number of admissions for enteric fever per 1,000 of strength in the army in India, and in the Punjab Command for five years. The years 1891 to 1894 inclusive are omitted, simply because in these years the Sanitary Commissioner did not

look upon the Punjab as a separate Command, and so its figures are not readily available :—

			Admissions for Enteric per 1,000 of strength.	
			India.	Punjab.
1888	18.6	10.6
1889	22.9	27.9
1890	18.5	20.4
1895	26.8	39.0
1896	25.5	25.9
Average			21.36	24.76

These few figures exhibit in all its simplicity and nakedness the little trap into which the Sanitary Commissioner was led to his downfall.

The first thing that will strike anyone looking carefully at the table, is that both in the whole of India and in the Punjab, the year 1895 is remarkable for having had the largest number of admissions for enteric fever in the series. Yet it is this exceptional year that the Sanitary Commissioner takes as his standard of comparison and from which he deduces the momentous fact that there was a large decrease in enteric fever in the Punjab.

There is however no reason why he should have compared the year 1896 with the year 1895 rather than with any other year, and it is evident that had he compared it with 1890 or with 1888, he would have been forced to alter his conclusions and to admit an increase instead of a decrease.

The fact remains that the amount of enteric fever in India and in the Punjab in 1896 was above the average, and the fact that it was less than in 1895, is merely an accident, due entirely to the abnormality of the year 1895, and not to the changes made in the water supply in 1896.

From the table it also appears that enteric in the Punjab is liable to considerable fluctuation from year to year, this point has not been given its due importance.

We cannot congratulate the Sanitary Commissioner on his methods in this case, nor have we the least confidence in his judgment when he says :—"It is to be hoped, however, that future results will be more striking than those of 1896." The results of 1896 are quite striking enough for us, they prove conclusively that the part played by the ordinary drinking supplies in the causation of enteric fever in India is very small ; and that many medical officers are of this opinion, is borne out by their individual reports, to which we may refer the reader.

THE PRESENT POSITION OF THE THERAPY OF TETANUS.*

II.

LET us now turn to the "Indicatio Causalis : " the first object of our therapeutic measures is to *destroy the exciting cause of the infection locally*. We know that the tetanus bacillus remains fixed at the primary seat of its introduction, and but rarely invades, or is borne into the interior of the body. From this situation it sends forth its alarming heralds in the form of toxins to the most distant parts. It is therefore of the utmost importance to find and destroy this lair, in order to prevent the farther spread of the toxin.

If there are no complications, the first thing that it is necessary to do is to enlarge and thoroughly disinfect the primary wound which may be considered to be the gate by which the infection enters.

This disinfection is of the utmost importance ; because it has been ascertained that nothing is so favorable to the development of tetanus as the association of other micro-organisms (KITASATO).

What influence have our usual methods of disinfection upon the tetanus bacillus ? According to KITASATO, corrosive sublimate solution, 1 in 1,000, is of little use, but if hydrochloric acid or tartaric acid be added, tetanus spores are destroyed in 30 minutes. The formula of LAPLACE is much used ; corrosive sublimate 1.0, tartaric acid 5.0, aquam add 1,000, or 0.5 hydrochloric acid may be added to a 1 per 1,000 solution of corrosive sublimate.

KITASATO found a 1.5 per cent. solution of carbolic acid more effective than corrosive sublimate 1 in 1,000. This is strongly antitoxic and neutralises tetanus toxin within an hour. A good preparation is that warmly recommended by SAHNI, tincture of iodine added to a 1 to 2 per cent. solution of trichloride of iodine, this is not only antiseptic, but also antitoxic. According to KITASATO, iodoform and subacetate of lead are useless.

Should more energetic measures be necessary for the destruction of the poison, the next step will be the destruction of the wound with the cautery. In carrying out this proceeding, ROSE recommends that all the recesses of the enlarged wound should be carefully cleaned out with small cotton wool swabs, soaked in chloroform, then the wound should be destroyed with the thermo cautery and finally a caustic applied.

As a further measure, extirpation of the wound may be indicated. This can only be successful when the bacilli can be totally destroyed at the seat of entrance, and when, in addition, sufficient strength remains in the system to overcome the toxin that has already been absorbed, either alone, or with our assistance.

As a last resort, in many cases amputation has to be performed. According to ROSE, there are 42 recorded cases of recovery under this treatment. He himself has only seen two cases of recovery in the Bethanien Hospital after amputation : once in an extensive burn of the hand, where amputation at the wrist doubtless preserved life ; in the other case, the fingers were amputated ; all the other cases died.

Still he recommends amputation ; for he says : "Now-a-days we can clearly see that amongst all the methods of

* By Von. Dr. A. Koldewey-Heldberg. Translated from Münchener Medizinische Wochenschrift.

treating tetanus, amputation, although the most mutilating, is also the most rational, where in suitable cases there is no better way of thoroughly antiseptizing the bacillus, which is the most important indication."

In general, amputation will naturally be reserved for those cases in which thorough disinfection is impossible in consequence of the complicated or soiled condition of the wound. Even in these it should not be undertaken until the symptoms of tetanic infection have appeared.

Unfortunately up to the present we have no certain indication of the incubation stage of tetanus, for such strongly suspected cases a prophylactic serum therapy, as in diphtheria, is of great importance.

We will return to this question later on. The second task that the Council Indication deals with, is the *elimination of the poison from the body*; it is here concerned with the methods of cure by elimination. The question that arises is—Can the tetanus poison, as a rule, be excreted by the organs of the body?

The result of researches undertaken by BRUNNER, KARTULIS and others to answer this question, is to show that the tetanus poison is present in the blood, and that it can be excreted by the kidneys, saliva and bronchial secretion. It is true that they found that inoculation with urine only gave positive results when the infection was a severe one. A certain precaution is necessary concerning these urine inoculations, in so far as the mouse, the animal usually employed, can only be injected with a very small dose; for with larger doses, even when healthy urine is used, the animal dies with tetanic spasms.

Success has not followed the efforts to demonstrate the tetanus poison in the perspiration. We learn from these researches that we are certainly justified in looking to diuretics to eliminate the poison. Still we cannot overlook the part that is played by diaphoresis; for, although the poison has not been found in the perspiration, empiricism has firmly established the beneficial nature of profuse perspiration in tetanus. Besides nature is especially mindful of this method of elimination, for there is hardly any other form of sickness in which we find such profuse perspiration, as in tetanus. The patients lie for hours and days actually bathed in perspiration. This has frequently been considered as a result of the permanent contraction of the muscles. It is not, however, improbable that there is, in addition to this, some action of a toxic nature upon the perspiration centre (SCHWAISSCENTREN).

In practice we have in one of our cases got good results from prolonged hot baths, 104°F.

The patient felt comfortable in the bath and afterwards there was a temporary diminution in the spasms of the muscles. In using baths it is well to take care that the patient is under constant supervision, and especially in the stage of increased reflex excitability, special precautions must be taken.

A case is reported by WILMS, where the patient was drowned in the bath, in consequence of a sudden and severe attack of convulsions.

We now come to the third task: the rendering inert, or *neutralizing the poison already in the body*.

Before entering into the details of the serum therapy, we will notice briefly some chemical methods which also, by means of injection, endeavour to bring about the des-

truction of the poison. In the first rank of these stands carbolic acid. IRANA reports one case of tetanus in which tetanus appeared on the 12th day after a wound of the great toe, which had been treated with catweb, urine, lime, and pig's bladder.

On the 15th day the toe was amputated, and three injections of carbolic acid after BACCELLI's method were given daily; after 16 days the patient was cured.

A second case is related by FIXA. On the 14th day after a lacerated wound of the great toe, tetanus appeared; the toe was amputated, there was no improvement with chloral and bromide, so in place of narcotics, a strychnine mixture was given with injections of a 2 per cent. solution of carbolic acid every six hours; the patient improved and recovered. A third case of recovery is mentioned by OCHEROWSKI; tetanus set in on the 6th day after a shot wound of the foot, from that time chloral, opium and morphia were given without result. From the 20th day injections of carbolic acid were given every two to three hours. After two days the patient improved and recovered. He was discharged on the 35th day after receiving the wound; 28 injections of carbolic acid were given. Besides these there are two or three other cases of recovery after injections of carbolic acid recorded.

We have gone somewhat minutely into these questions, because ROSE has denied the good results of the serum treatment in several cases; for he says, it is possible that the good results obtained in these cases was due to the carbolic acid contained in this serum. It is naturally difficult to prove this. We must always remember that the carbolic acid treatment has had some favorable results. Still the first two cases mentioned were mild, but the last was middling severe.

Amongst other drugs that have been injected must be mentioned permanganate of potassium and corrosive sublimate, both in a one per mille solution and combined.

In a case of TRAFINOW'S, where the circulatory system was severely affected, the tendency to hemorrhage, disappeared under this treatment. The case is, however, not clear; since, besides morphia, chloral and hot baths were given. Still it is said that, when the injections were stopped, the former symptoms re-appeared, which appears to show that they had a beneficial effect.

By far the highest interest of these questions lies in the subject of serum therapy, the grounds for this method of treatment, and the results of experimental investigations, are laid down by BEHRING, KITASATO, and KROOK in different works, and KROOK has in his thesis (1895) defined the limit beyond which a cure cannot be expected from serum therapy.

He discusses the prospects held out to man from the results of experiments performed on animals. He asks—"What can we infer, from the positive results already obtained, concerning the possibility of cure, and the applicability of the treatment to man; and what are the prospects of bettering the results?"

He concludes that "we are justified in the expectation that the possibility of cure in man will not be less than in animals, success has indeed already been gained, for at least some cases of severe tetanus have been saved by the energetic application of tetanus curative serum."

Since then the statistics of cases treated with curative serum has quickly increased; so that at present the grand total of published cases that have been treated with some form of tetanus serum exceeds 100.

The amount of interest that has been taken in this question is well illustrated by the fact that we can already count nine different tetanus antitoxins. Besides those of BEHRING and TIZZONI-CATTANI which are the best known, we have those of ROUX and VAILLARD, of PASTEUR, of BABES (KITABATO), of TAVEL, of DUNCAN and FLOCKART, of PARRE DAVIS and Co., in Detroit, and lastly that of the British Institute of Preventive Medicine.

The preparations, which are specially interesting to us, are those of TIZZONI and BEHRING, because we have more experience of them and because they were the first accessible to us.

Last year ENGELMANN undertook a comparison of the results obtained up to date with these antitoxins, including three cases of his own, he found 36 cases treated with TIZZONI's and 18 with BEHRING's serum.

To the former we have been able to add 2 from the literature of the subject, and to the latter one earlier case, and 7 new ones that appeared last year, making 10 altogether. This makes the grand total 38 with TIZZONI's and 28 with BEHRING's serum.

According to ENGELMANN the results obtained with TIZZONI's preparation are very satisfactory; for the parti-

in Koch's Institute, it does not possess the immunising power of $\frac{1}{10}$ mill and especially that it is three times weaker than the BEHRING serum of $\frac{1}{3}$ mill. Nevertheless, the further observations and results of known cases do not appear to bear witness against its favorable influence, and two of ENGELMANN's own cases, which he has recorded, show that the serum undoubtedly exercised a beneficial action. Further, in the British Institute of Preventive Medicine, an analysis of the effects of the various curative serums was made by Dr. KANTHACK, which showed that in the cases of tetanus treated with TIZZONI's serum, the mortality was only 25.6 per cent., while it was 60 per cent. in the cases not treated with serum, and about 60 per cent. in cases not treated with ROUX's serum.

We give below the two cases treated by TIZZONI's serum which were not included in ENGELMANN's table.

Concerning BEHRING's serum, it is also necessary to distinguish between an earlier and a later preparation.

Of the 18 cases given by ENGELMANN, 13 were treated with the early preparation (blood serum from the rabbit, sheep, and horse), 5 with the new serum, No. 100. Of the first, 6 died while 7 were cured. Of the last one died, which was only injected for the first time five hours before death; the others recovered. In the first mentioned cases, it appears that for a good result, everything depends upon the immunising strength of the serum, $\frac{1}{4}$ mill is of little value, $\frac{1}{10}$ mill has a decided action, but even with it

(TABLE I.—TIZZONI'S SERUM.)

No	Author.	Onset of disease.	Incubation.	Therapeutic effect.	Other effects.	Result
1	Firth, <i>Brit Med Jour.</i> , 1895.	Tet. Neonat. 8 days after birth Tet. Asphyxia on drinking.	...	At once chloral and bromide every 4 hours. On the 8th day after onset 0.4 A.T. four times	..	Death
2	Darbyshire, <i>Lancet</i> , 1897.	Tet. Traumat. Youth of 13 years Nail wound in foot. After 14 days (a) trismus; (b) spasms of arm.	14	From (a) bromide and chloral, three times daily. (b) A.T. 1.35; worse Chloral every four hours; better after four doses	Recovery.

culars we must refer to the original article (this Journal No. 32, 1897).

ROSE's criticism of TIZZONI's preparation is not so favorable as ENGELMANN's, in the first place he finds fault with him for employing the serum of the dog, since it is well known that the dog is only slightly susceptible to tetanus; then the 9 cases (he refers to the first publication of 2 cases treated by TIZZONI's method) were so mild that they could have recovered spontaneously.

With reference to the newer horse serum, ROSE points out, that, according to investigations carried out

large doses must be given.

BEHRING's first serum was therefore not strong enough, and was administered in too small doses.

The new serum No. 100 must also be given in large doses. In a case of ENGELMANN 20g. to 2.5 was given on a single dose, and entirely free from injurious effects.

ENGELMANN sums up the results of his experience with TIZZONI's and BEHRING's serums in the following propositions:—

1. Both TIZZONI's and BEHRING's tetanus antitoxin exercised a favorable influence on the course of the disease.

3. They are harmless even when given in large doses.

4. It is therefore recommended to administer them as early as possible in sufficiently large doses according to the severity of the symptoms.

5. No distinct difference can be detected in their effects.

Let us examine the 8 cases, not mentioned by ENGELMANN, which were treated with BEHRING'S serum. (Table II).

whilst other coincident and other effects have not been published.

In one of our cases we observed an exanthem after subcutaneous injection.

A further case reported by WEISCHER from the Leichtenster Clinic must be counted very severe, as it began on the fourth day; after an injection of 5 g. A. No. 100 given on the 8th day, the symptoms became less severe,

TABLE II.—BEHRING'S SERUM.

No.	Author.	Onset of Disease.	Incu- bation.	Therapie and Effect.	Other Effects.	Result.
1	Blumenthal, <i>Zeitschr. f. Klin. Med.</i> Bd. 30.	Tet. Puerperalis	Dried serum Strength $\frac{1}{1,000,000}$	Death.
2	Bokey ...	Tet. Traumat ... (1) Child 5 years old, wound of hand.	...	In 6 days 80 cc.m. A	Recovery.
3		(3) Infant 4 years old. Infection through naval	...	5g. No. 100. Treatment well- borne. Result not yet stated.
4	Asam, <i>Munch. Med. Wochenschr.</i> 1897, p. 32	Tet. Traumat ... Child 11 years old, wound of foot, after three weeks. Tet. quickly developed.	21	Onset, chloral and morphia, then A.B. 5g. in 50H ₂ O in the great saph. vein. Next day diminished spasm and trismus. Steady recovery.	Urticaria rub. with bullae of face, back and thighs.	Recovery.
5	Weischer, <i>Munch. Med. Wochenschr.</i> 1897, p. 46.	Tet. Traumat ... (1) Male, 29 years old, lacer- ated wound right ring finger, after 4 days trismus follow- ed by general convulsions.	4	8th day after onset 5g. No. 100 in 4 places. Worse for 2 days; after that considerable relief and steady recovery.	Recovery.
6	(2) Tet. Rheumat. ... Male, 37 years old, after a thorough wetting trismus and tet.	...	17th day, after onset 5 g. No. 100 in 4 places, from follow- ing day steady diminution of spasm.	...	Recovery.
7	Rose, <i>Deutsche Zeitschr. f. Chir.</i> Bd. 46.	(1) Boy, 10 years old, cause unknown.	?	4 days after onset 4.0 No 100 intra venous, the following day 1.0 subcut. No improve- ment.	Measles-like rash appear- ed on 17th day.	Recovery.
8	..	(2) Tet. Neonatorum ... Infant 6 days old. Navel in- fection.	?	On 7th day 5g. No 100, sub- cut in different places (within 36 hours). No effect, died after 2 hours.	Death.

We note that one died which was treated with a very weak serum $\frac{1}{1,000,000}$; this was a case of puerperal tetanus.

A second reported by ROSE also proved obstinate to early injections.

Five cases recovered; in one the result is not yet given. This was a suckling infant 4 months old, who contracted tetanus after injection of the navel and received 5g. No. 100. He stood the treatment well. In another case, reported by the same author, a girl of 5 years of age was given in 6 days 80 cc.m. A., and also 10g. dried preparation. One case (Asam) first developed three weeks after a wound of the foot, and immediately assumed a serious character; in it injections of 5g. No. 100 were given in the saphena magna vein. On the following day the spasm and trismus had diminished and the case gradually recovered. In this case, the serum produced an urticaria rubra et bullosa of the face, back and thighs.

Slight eczema has also been observed by others after serum injection. In one case of ENGELMANN, treated with BEHRING'S serum, there was a papular exanthem,

and after a second, two days later, undoubted relief was felt. A second of WEISCHER'S cases was also cured; in this case, the way the poison entered the body was unknown, wherefore he distinguishes it as rheumatic tetanus; it cannot be accepted as strong evidence of the beneficial action of the antitoxin.

As for the first of ROSE'S cases, an idiopathic case, without local site of infection, it cannot be fairly compared with traumatic tetanus.

No conclusions can be drawn from the fact that the antitoxin was ineffectual in these obscure cases, besides the case recovered, and it would not be possible to prove conclusively that the antitoxin had had no beneficial action. The second case died so quickly (two hours after the infection) that it is clear that so late nothing could have been expected from the injection.

In an impartial view, these two cases cannot be considered to prove anything unfavorable to the serum treatment.

Of our cases which were treated with BEHRING'S serum, the two first were injected with the dried preparation.

(5 g.=500 I.-E., in 45 cc.m. of water) the third with the new fluid that was received in the following doses from the Hoechst Chemical Works :—

A single dose, 2 small flask 25 cc.m., 10 fold=500 Tet. I.-E.; in adults and horses they should be injected under the skin immediately decided signs of tetanus appear. In children the contents of only one flask (25 cc.m.=250 Tet. I.-E.) should be given. On the following days the injection of one-half dose is recommended, even though the patient is better.

The following is the first case that was treated with BEHRING's antitoxin :—

"(1). FLORIAN V., 43 years old, agriculturist, on the 11th October 1897, while trying to restrain the frightened horses of his wagon, was thrown down and dragged by the reins about 50 yards. He received several wounds : one on the head, one on the right elbow, a fractured rib and a contusion on the inner side of the right thigh.

The open wounds on the head and elbow were at once cleaned and dressed by a surgeon. Until the 20th of October he lay in bed and had but little pain.

On the morning of this day, the 9th after the accident, spasms of the right arm appeared suddenly, accompanied by severe pain. They came on about every five minutes and lasted with unchanged frequency until to-day, but with increased severity; five days ago, pus was squeezed out of the deep parts of the wound in the arm, while at first the secretion was altogether superficial. Since yesterday the patient has noticed that he could no longer open his mouth, and painful spasm of the muscles of the jaw has set in, which is permanent and not paroxysmal.

The surgeon, accordingly, sent the patient to the Clinic to-day.

Present condition.—25th October (the 14th day after the injury, and the 5th from the onset of tetanic symptoms). A strong, apparently healthy man. Expression of face fixed, like a laughing mask (risus sardonius); the mouth is tightly shut, and the patient can only separate the teeth by a strong effort to the distance of 1 millimetre. Speech indistinct in consequence. No difficulty in swallowing or breathing. Fluid nourishment can be taken without much trouble and swallowed.

On the scalp, almost at the junction of the left parietal and occipital bones, there is a superficial abrasion, otherwise no wound of the head.

The right arm remains flexed to a right angle at the elbow joint, with the forearm pronated, the arm is strongly abducted and the forearm and hand lie against the body. The hand is slightly flexed at the wrist, the index finger is stretched out, the thumb completely flexed, and the other fingers bent.

All the muscles, as high as the deltoid, are in a condition of tonic spasm, and feel as hard as wood; touching the arm excites a paroxysmal convulsion, which causes the hand with the out-stretched fingers to be pressed so strongly against the body that the nails sink into the skin, which bears the marks of linear scratches. These paroxysms recur every couple of minutes and appear to be very painful, so that the patient sometimes screams loudly. On each occasion he is more or less generally convulsed, yet so far it has not been definitely noticed that the muscles of the body take part in the convulsion.

On the inner side of the right elbow joint, close to the internal epicondyle of the humerus, there is a wound 1.5 cm. long, by 0.5 broad, which is granulating at the bottom and discharging slightly; the wound appears healthy. No sinus leading to the deeper tissues can be made out with the probe; the neighbourhood is slightly red and inflamed, but there is no sign of an abscess forming or of retained secretion.

The abduction of the arm necessary for the examination of the wound is obtained with difficulty, and only by very cautious and slow elevation. As soon as a spasm occurs, the arm returns to the position already described with irresistible force.

The lungs and heart are normal; the pulse somewhat quickened; no alteration of the pulse during the spasm; abdominal organs not affected; bowels confined; urine clear, acid; no albumen; no sugar. Temperature 99.7°F.

Clinical diagnosis.—Traumatic tetanus, caused by a wound of the right arm. Trismus.

One hour and a-half after admission the patient was given an injection of tetanus antitoxin (10 g. of the dried preparation=500 I.-E., dissolved in 45 cc.m. of warm water) the injection was given at 3 o'clock in the afternoon in the median vein of the left, the sound, arm. During the day there was no reaction.

The temperature rose to 100.7°F. Pulse 112

During the evening and night the paroxysms were very frequent and painful, an enema of chloral hydrate in mucilage was administered without much effect, and it was only towards morning that sleep was induced.

26th October.—This morning, about 18 hours after the antitoxin injection, decided improvement, paroxysms less frequent, about once every quarter of an hour with less pain.

Subjective symptoms more favorable. Reflex excitability appears less. No marked change in the tonic spasm of the muscles of the arm. Temperature 99.5°F.

Evening.—Patient worse, the spasms are again much more frequent and painful; difficulty of swallowing for the first time; breathing regular; trismus unchanged, profuse perspiration. Tincture of opium given.

27th October.—Morning temperature 100.7°F., he feels well and the objective appearances are better. Locally there is no change, no other group of muscles affected. In the evening an enema of chloral hydrate was given, slept better; spasms less painful.

28th October.—Morning condition unchanged; got much worse in the afternoon, at each spasm a tendency to opisthotonus appeared, and spasm of the left leg; in the evening there was also spasm of the right leg and of the muscles of the abdomen. The muscles referred to are stretched as hard as wood, and in the intervals between the paroxysms there is not complete relaxation; severe pain. Opium and chloral given during the night; he had five hours' unbroken sleep.

29th October.—In the morning paroxysms came on about every quarter of an hour, only they are short and there is but little pain, but still the other muscles of the body participate in them.

The muscles of the abdomen are stretched and tense. Towards evening another aggravation occurred. Spasm

in both legs well marked. After opium and chloral the patient slept the whole night.

28th October.—In the morning the patient was undoubtedly better, both subjectively and objectively. Afternoon another aggravation; more profuse perspiration; he takes his nourishment well; is very thirsty and drinks plenty of milk; bowels confined, moved by enema. Opium and chloral given at night.

31st October.—Better again this morning; aggravation towards evening. The reflex excitability is still so enhanced, that the patient, if touched, almost always has a tetanic spasm; noises, or the opening or shutting of the door, or the light of the lamp falling suddenly upon the patient are sufficient to start a paroxysm.

The perspiration has been most profuse during the last day, although the patient has not been extra warmly covered. Trismus unchanged; swallowing again easy; breathing normal; only slight stiffness during the night.

1st November.—Morning same condition. In the evening very severe and painful spasms, during which the patient screamed loudly from pain. Opium and chloral gave but little relief; almost no sleep.

2nd November.—On account of the increase in the symptoms the intravenous injection of antitoxin was repeated to-day at 1 P.M. (5 g. dried preparation in 30 ccm. of warm water); the preparation was sent to us direct by BEHRING.

Immediately after the injection there was half an hour without any paroxysm, and for the rest of the afternoon they were infrequent. The temperature rose in the night to 102.5°F. The pulse increased to 120 per minute. The night, on the whole, was much better than the previous one.

The persistent trismus was better in the evening and the patient himself remarked that he was again able to open his mouth.

3rd November.—Morning temperature 101.4°F.; fell during the day to 100.4°F.; the improvement to-day is striking and differs completely from the usual morning remission. The trismus is certainly waning; the patient can now open his mouth easily to a distance of 1.5 cm. and he can put out his tongue which before was impossible. The tonic spasm of the muscles of the abdomen and thighs is abating visibly; in the arm the signs are not so striking, but the patient can, of his own accord, lift the arm a little. The stiffness of the facial expression is disappearing; the movements of the body are perfectly free. Paroxysms of much diminished severity now occur about every 20 minutes.

In the evening they were again more frequent and more painful, so that chloral was again given.

4th November.—No apparent change; chloral given at night; temperature normal.

5th November.—Trismus still better; paroxysms now confined to the arm; they are not so frequent or painful as formerly and occur about every 10 minutes. Patient felt very tired to-day and slept well; chloral.

6th November.—He was given a hot bath at a temperature from 102°F. to 104°F., in which he remained about one hour; after this he felt very well. He complained to-day of a very painful spot on the right elbow and a red swelling of the size of a pigeon's egg was discovered.

With great care, on account of the spasms, and which reflex spasms are excited by contact, and by movement of the arm, an incision was made under strict asepsis, over this spot (between the epicondylar space and the olecranon). No formed pus was evacuated, the only altered and discolored blood (contamination with pus was negative).

In the evening the spasms were more severe (about every quarter of an hour); chloral and opium.

7th November.—No fever; the patient, during the whole day, had tetanic spasms every half hour, which were limited to the arm and much less painful. Trismus disappearing steadily.

There was an aggravation towards evening; chloral and opium continued; profuse perspiration during the night.

8th November.—Prolonged bath; paroxysms less frequent (hourly); the arm is not so stiff and can be slightly abducted; the fingers can be straightened, but causes pain. He feels very well.

9th November.—The patient slept soundly during the night and feels very well. During the day there was not a single paroxysm.

The wound on the arm is granulating; swelling continues about the elbow.

10th November.—During the night the patient had much severe pain and frequent spasms in the right arm; had a bath; no paroxysm during the day, although there was permanent pain in the arm; no change noticed objectively. During the night there was again much pain but no spasm.

11th November.—Free from spasm all day; slight pain; severe pain in the evening; chloral and opium gave no relief. After a subcutaneous injection of morphine he felt better and got some sleep.

12th November.—Feels well; arm slightly painful; spasm of the muscles unchanged; still the spasm of the other affected muscles has completely disappeared.

14th November.—Rarely has pain in the arm; no tetanic spasm for the last four days; movement of the fingers better; active flexion and extension possible without much pain. Temperature normal the last 11 days.

15th November.—Muscular spasm limited to the arm; the deltoid is hard as though in strong contraction; also the biceps and the pectoral muscles. The patient can move the arm a hand's breadth from the body to-day.

16th November.—The movement in the shoulder joint is gradually getting stronger; the elbow joint is still motionless; massage and passive motion caused so much pain at first that they had to be stopped; only light rubbing can be borne.

19th November.—Bath; no marked change; patient got up for the first time to-day.

20th November.—Rubbing and gentle passive motion of the joint were borne to-day; flexion of the hand and fingers caused considerable pain, but extension is not so painful. Trismus completely gone.

22nd November.—The electric excitability of the affected muscles was tested by Professor HOFFMAN and found normal.

23rd November.—Energetic massage, and movement exercises caused severe pain to-day, which lasted all night; se-

the patient, who has hitherto been feeling thankful for his recovery, felt much depressed.

17th November.—Massage and passive motion have been continued daily; there is a decided improvement in the movement of the arm. The patient was discharged to-day at his own request. The stiffness of the muscles of the arm is still marked, but this is all that remains of the tetanic condition."

(To be continued.)

—o:—

WHAT ARE THE PROSPECTS OF INDIAN GRADUATES IN MEDICINE?

In reality a dreary, weary, up-hill struggle with State-aided competition to fight against at every step and sudden State ukases that preserve official monopoly at the risk (should we say with the deliberate intention?) of depriving the non-official practitioner of his bread and starving his wife and helpless babes; but either from crass carelessness or with a view to canvassing for more students at the medical colleges the *Indian Medical Gazette* paints a very glowing picture, *all couleur de rose*, of State appointments, Civil Surgeoncies, Assistant Surgeoncies and redundantly lucrative fields for private practice, whether as independent practitioners or as overtime in subordinate official life, in store for Indian graduates in medicine, the proportion of whom to available State appointments is something as 3,000 is to 1: a soul stirring and ambition inspiring outlook; is it not?

Of course we cannot blame our subsidised contemporary for trying to extol the par excellence of the Indian Medical Service who are its bone, flesh, blood, nerves and marrow, although it is the private and absolute property of an enterprising firm of Booksellers, Stationers and Publishers, who spend a lot of money on it: but it behoves us to sound a dissentient note when it goes in for whole sale but totally undeserved stigmatising of the non-official practitioner, and clamours for more privileges for the already too much privileged and theoretically hard-worked though in reality next-to-nothing-to-do higher official.

That there ~~was~~ a time when India stood badly in need of qualified medical aid, and that the Indian Medical Service was permitted, to meet this urgent want, we all admit; but that *that* time has long since vanished is amply proven by the facts that the banking accounts of the I. M. S. are not near a tenth of what they used to be only fifteen years ago, and that, comparatively speaking, India now has nearly twice the amount of the fully qualified medical aid available in the British Isles. Year after year adds to this number many of whom could emulate a SYME, a PLAYFAIR, a FAYRE, or a MACLEOD, and whose names would be on every tongue if they were only found the opportunities the Government MAKES for its pet *clientèle*, the I.M.S. So that when the *Gazette* contends for a continuance of I. M. S. surveillance and monopoly of the fields of practice, it is somewhat in the position of the ancient matron who, making no allowance for the growth in mind and body of her sixty-year-old son (himself a grandfather perhaps) still looks upon him as "my boy," whom she is continually advising "for his good" and asking for the same deference to her views and wishes as he did in his baby days.

We are extremely chary of accusing our contemporary of wilful untruth, when his statements, which are incorrect,

may be the result of not being in contact with the progress of medical politics; but we would point out that there are several ways of putting facts, and though the majority of them are not strictly true, they are also not wholly untrue.

Thus the honest way of telling the truth is a plain statement of facts, which conceals nothing, and going the full length of complete confession, pleads no extenuating circumstances, not even to save oneself from punitive or unfriendly consequences. This mode, though of immense value to the practical man, is more than often unpalatable, and under the strained relations that exist between officials and non-officials, is considered impolitic by the former, who usually adopt one or other of the following methods to excuse or justify themselves in Parliamentary gaze, lest they may lose the advantages granted to, but not *always* merited by them.

The second consists in admitting the charge but immediately pleading a vast array of circumstances, which it is pretended, forced the acts complained of. (3). Is an evasion of actual confession by hiding the actuality in a mass of cunningly disposed superfluous verbiage that in most instances is understood in an entirely different way to what the confessor pretends he really meant it to be. (4). Beginning with platitudes of the parties addressed or unlimited slating of the parties concerned says a great deal that is neither admission nor denial, and in the end confesses *nothing*. (5) The official mode of burking too close enquiry by statements of the diplomatic delphian oracle character which, like the clever *Roma vista est*, cuts either way equally sharp and seemingly savors of the sanctity of truth, which it really is not. (6). Disclosure of partial facts with deliberate suppression of the more pertinent portions, the disclosure of which might not subserve interested motives, while the disclosed portions are told in the sincere hope that they will work back to the end desired by the wily confessor, and (7). The truth told in such a way that it really confesses nothing, though the only possible inference it leads to must eventually harm the community it is secretly hurled at in deadly hatred, though it ostensibly pretends to protect their interests.

Thus while informing the public that apart from the appointments offered by the Indian Government, "many of the Native States possess well-organised medical services offering honorable employment on a liberal scale of pay, &c. Our truthful contemporary conveniently forgets to say that the majority of the States that possess such "services" also have their own medical schools to whose graduates they certainly give the preference for employment.

Then forgetful of the fact that the *Gazette* notification of 1894, which demanding medical certificates signed by I. M. S. officers only, under the rôle of Presidency Surgeons, to each of whom it relegated a large and onerous class of officials who had hitherto exclusively entrusted the care of their ill health to non-official doctors, essentially deprived the independent medical man of at least three-fourths of his legitimate income by also ruling that a Government clerk, &c., in ill-health could, for the small sum of Rs. 4, compel a Surgeon-Major, Surgeon-Lieutenant, Colonel, &c., to give him a certificate of his state of health,

which certificate the private practitioner would not have written for less than Rs. 8 or 16. The *Indian Medical Gazette* prophesies "that the openings for private practice are so increasing" that the prospects of medical men in India are exceedingly hopeful, more so indeed than in some European countries," and then stultifies itself by admitting "yet the manufacture of graduates of medicine is increasing steadily, and is somewhat in excess of demands."

Next ignoring the patent yet more than often untruthfully denied fact that "its *pet clientèle*" do receive "commissions on their prescriptions," the *Indian Medical Gazette* has a slap at those European and Anglo-Indian non-official practitioners, who are honest enough to openly dispense their own prescriptions or as openly sit (not on commission but on regular salary) for the purpose of giving medical advice at those very dispensaries from which its "*pet clientèle*" derive their handsome "commission on prescriptions" and by some intensely peculiar slip of the pen, our esteemed contemporary says: "In recent years the great majority of graduates and licentiates of one of the Indian Universities have found employment of this nature, either permanent or temporary, within a few months of passing their examinations," when if it really meant to tell the truth, it should have said "the great majority of those few graduates, &c., who have been selected from the many hundreds who have passed out of one of the Indian Universities, to wit, the Calcutta Medical College, have been appointed within a few months of their passing their examination." This reads very differently, but it is nevertheless a fact that can easily be proved by reference to the "roll of graduates."

There are a number of other discrepancies and iniquities that space will not permit special reference to; but it goes without saying that if the *Indian Medical Gazette* only took the trouble to look properly into matters instead of emulating the war artist, who never heard a shot fired or saw a bayonet fixed or sabre drawn, of the fierce battles he portrays on canvases in some safe nook, thousands of miles away from the seat of action, it could not honestly depict the glorious future it prophesies in a more than congested field for medical practice, and certainly could not urge the fractional part of a single sane reason for the glamour with which it surrounds the Indian Medical Service and damns the non-official practitioner.

Our own columns have times without number adduced more than sufficient proof of the unjust and unkind manner in which the independent practitioner is hounded to death and severely handicapped at every possible point by State-aided competition and by free advertisement of official medical men in the Government Gazettes and in the medical and lay papers.

We have shown the immense harm done to the public by pitchforking an accoucheur into the materia medica or chemistry chair, or suddenly converting an eminent chemist into a store-keeper, obstetrician or pathologist, and it now remains with the Government to fulfil the promise it made to its thousands of medical students and save its millions from wholesale destruction. God help us if the State wot.

CIVIL PLAGUE MEDICAL OFFICERS.

FORTY-FOUR years ago, JOHN BRIGHT said of India: "I am very anxious to see a much wider employment of the most intelligent and able men amongst the native population"; but though India and her subordinate services are full of very capable men, more than competent to hold much higher offices than they at present do, Lord GEORGE HAMILTON seems to think that "skin" makes such a difference in mental calibre, that an Indian, who has rendered 5 to 13 years' good and faithful service after passing his M.B., C.M., or winning the "triple qual" of Scotland, is inferior mentally to a European who has only just got through his "Double Qual." or even the L.S.A. examinations and does not know sufficient Hindustani to ask for a drink of water, much more tackle the stupendous task of plague enquiries.

It seems a case of "importing coals for Newcastle," for with oceans of indigenous talent at its immediate disposal and the option of selecting from its existing Military and Civil Assistant Surgeons, tried men whose long experience of India and her dialects, religions and customs, peculiarly and especially fitting them for effectually dealing with matters that the illiterate masses always have a misconception of, still because of the benefits expected to be obtained from raw English material caused the Madras Government to advertise in Great Britain for eight medical men for plague duty. These men were to receive Rs. 500 per mensem each, and the Secretary of State engaged them for one year certain.

If these doctors had any special qualifications as biologists or were sanitarians of long and tried experience, we might have nothing to say against their engagement, but when Government is continually complaining of financial difficulties, it does seem strange indeed and unjust too that Rs. 48,000 should be taken out of the public exchequer for the maintenance of eight young men, fresh from college, who have been told off to civil holdings that ought in common justice to be given to deserving Assistant Surgeons, as some little return for their faithful services, while the "plague work" for which these six gentlemen were ostensibly imported, has been assigned to the higher officers of the Indian Medical Service, and the claims of the Assistant Surgeons have been deliberately ignored.

This is how these "Plague (?) Doctors" have been disposed of:—

- (1). F. V. O. BELL, M.B.C.S., to be District Medical and Sanitary Officer, South Arcot.
- (2). A. C. RENDLE, M.B., B.C., to the General Hospital, Madras.
- (3). S. F. LUMK, M.B., C.M., to be District Medical and Sanitary Officer, South Canara and Superintendent, Mangalore Jail.
- (4). S. S. NIGHTINGALE, M.B.C.S., civil charge of Kurnool District.
- (5). J. W. G. MYLER, M.D., M.B.C.S., to be District Medical and Sanitary Officer, Cuddapah.
- (6). C. S. LANGLEY, L.R.C.S., L.R.C.P., to the General Hospital, Madras.
- (7). T. W. ILLINGWORTH, M.B., C.M., M.D., to the Government Maternity Hospital, Madras.
- (8). G. CHARLESWORTH, L.S.A., to be District Medical and Sanitary Officer, Godavery.

No. 1, who is only an M.B.C.S., supercedes Assistant Surgeon R. SUNDARAM, M.B., C.M., who has rendered 5 years'

exceptionally good service at South Arcot; while Assistant Surgeon J. St. G. De B. BARTLEY, L.M.S., L.R.C.S. & P. (Edin.), L.M.S. (Glas.), with his 13 years' good service, has to play second fiddle to an L.M.S. at Godavari District, and Mr. GANAPATHY, L.M.S., who is held in high repute all over the West Coast and during his 14 years' tenure of office has frequently acted as District and Civil Surgeon of large and important districts, has to make over his present post of District Surgeon, Mangalore, to Mr. LUSK, a fresh arrival from England.

It is more than palpable that the rule that half a dozen Civil Surgeons should be filled by Indians is a dead letter, not from dearth of competent men, but from that bias which will not maintain the balance evenly between Indian, Anglo-Indian and European medical officers.

If these imported doctors are really necessary for plague duty, why have they not been sent to Arkonam, Guntakal, Hospet, Kondapalle, Perambore, Pothanore, Trichinopoly and Tuticorin to replace the pensioned men stationed there and relieve the Government of an additional expenditure of Rs. 26,000, the light-hearted squandering of which is by no means pardonable in the present state of Indian finances, and the entertaining of the plague doctors—if there be no valid reason for their engagement or stations available for them to be posted to—appears to be a piece of whimsical patronage, or rather a State lottery, by which anybody may be pitchforked into anything; appointments being created for men instead of men being found for existing vacancies.

Personally, we have nothing against the "Doctors from England," who are neither Commissioned Officers nor in any way specially qualified for the Indian Medical Service, to which they have no sort of claim, whether as to privileges or the obedience expected from its subordinate branches, both military and civil; but we cannot understand the justice of importing them to Madras in the name of "plague" and thrusting them in charge of districts as District Medical and Sanitary Officers, to the utter exclusion of Assistant Surgeons possessing Indian as well as British qualifications in no way inferior to those of the new doctors over whom they also have the decided advantages of longer experience and an intimate acquaintance with the religious and customs of the people with whom they will have to deal in these civil posts,—a no easy matter to properly and satisfactorily handle.

To say the least, the present policy of the Madras Government is altogether unjustifiable, and it is indeed a crying shame that Indians and Anglo-Indians, who go all the way to England and obtain British medical qualifications at great expense and inconvenience to themselves, should find their best hopes and highest aspirations most cruelly blasted, for no better reasons than the accident of their birth and the color of their skin, more especially after all the worry and work that has fallen to their lot in their long service which seemingly does not merit the reward of adequate recognition, though they have ever been willing, yes and eager, to help the Government in time of war or pestilence.

We appeal to Sir ARTHUR HAYLOCK's well-known sense of justice to consider if he can do nothing to remedy or put a stop to such gross injustice to a class of men who deserve better treatment at the hands of the State.

COMMENTS AND NEWS.

WILLIAM FORBES-LESLIE, M.D., O.M., ADDRESSING, ON THE PATHOLOGY AND TREATMENT OF MALARIAL FEVER.

A PAPER of considerable interest and suggestiveness appeared in *The Lancet* of 4th June, by the above-named author, entitled "Malarial Fever, some suggestions to its Pathology and Treatment."

It is necessary, in the first place, to remark that Dr. FORBES-LESLIE is far from accurate regarding the malarial parasite. He tells us that, "Italian observers lay claim to its discovery," and that "KLEBS was the first to demonstrate this theory by the discovery in the blood of an organism which he believed to be that of malaria."

It is of course unnecessary to remind our readers that the malarial parasite was discovered by LAYERSAN, a French Army Surgeon in Algiers, and that KLEBS was merely associated with TOMMASI-CRUDERI in the discovery of a bacillus, which they called the bacillus malarie, and which has long since been proved to have absolutely nothing to do with the disease, and which is an entirely different organism from the parasite of LAYERSAN, which is not a bacillus at all but an animal parasite.

Dr. FORBES-LESLIE holds several other very curious ideas about malaria which, we imagine, will not meet with ready acceptance, chief amongst these is its connection with other diseases. "Some observers," he says, "are inclined to grant it an epidemic power, and this I believe it has in certain of its independent forms, such as influenza, malarial cholera, yellow fever and dengue." Again, he says: "We may read a malarial origin in pneumonia, typhoid fever, cholera, dysentery, enteritis, yellow fever, malignant endocarditis, multiple neuritis, locomotor ataxy, myelitis, meningitis, lunacy, hepatic troubles, kidney disease, blood diseases, skin diseases, and a host of others, not forgetting the bleeding diathesis."

It is not, however, to notice these lapses and peculiarities of Dr. FORBES-LESLIE that we have introduced the subject, so we will pass over them lightly and come to what he has to say on the subject, first, of treatment and then of pathology.

This branch of the subject he has had a large experience of—twenty years he tells us—and he has studied it carefully. "Where quinine," he says, "was discovered to have a favorable effect in malaria, it was at once conceived to have a specific action. That it has a favorable effect is beyond doubt but a specific action would indicate that it cures the disease—which it certainly does not. I came to this conclusion from a study of both the Indian and African fevers. The method of giving quinine in large and frequent doses is sometimes a source of danger * * in the deadlier forms of ague it is most pernicious."

"Experimenting with drugs, I found that jalap had no effect on fever. With calomel I had a different result." In that form of malaria where uncontrollable vomiting is the prominent symptom, its action was instantaneous. In the comatose form its effect was equally rapid, in the continued fevers it cut short the attack. In hyperpyrexia it immediately reduced the temperature. In agues it had the effect of at first confining the stages and then preventing them." "Usually I gave 3 grs. at first in cases in which there was constipation and 5 grs. in those in which laxity of the bowels was a prominent symptom. Twenty-four hours after I administered a smaller dose, and if there was no severe purging in 56 hours, still smaller one."

"Large saline draughts should not be given with calomel

to hasten his action, but soda and plenty water in small quantities to quench thirst."

"I cannot recommend pepper too highly as a stimulant in malaria."

Regarding biliary stimulants he says:—"I was not long in discovering that they were injurious, showing that increased secretion of bile without proportional oxidation reacts unfavorably."

"I have found fever to be induced by a full diet of meat and fat."

"I find that quinine has a more favorable action on the poison after the administration of calomel, than without it."

"I experimented with several drugs said to give antiseptic properties to the blood, such as salicylic acid, arsenic, potassium iodide, and carbolic acid. I got the best results from carbolic acid, but better results still by a combination of carbolic acid and quinine in solution, 1 gr. of carbolic acid to 3 grs. quinine in sulphuric acid and water to loz. every four hours. In my hands it has been practically a specific."

"In the after-treatment, the principal object is to nourish the patient, at the same time keeping close watch on the liver, regulating any derangement at once, keeping the paths of excretion open, and giving a diet largely consisting of carbohydrates. Alcohol must be sparingly indulged in; excess is fatal."

"Another point which is not generally known is that a sea voyage is unfavorable unless the patient is fully convalescent."

PATHOLOGY.

We will now turn to his views upon pathology. "My opinion is," he says, "that the true malarial germ has not yet been discovered." He discusses MASON'S mosquito theory and disagrees with his conclusions. He believes that there is a special organism which has not yet been discovered.

"I cannot bring myself to consider malaria other than the result of the products of the developmental energy of the organism outside the blood-stream, and some of the facts which have led me to this belief are that preceding the fever there is invariably a stage of hepatic congestion and signs of bile in the blood; the proneness of the disease to attack the *primæ viæ*, as evidenced by gastric derangement, enteritis, dysentery, and typhoid fever; the peculiar liability of the liver to acute inflammation with abscess as an extension from the *primæ viæ*; the induction of the algid malaria through the *primæ viæ*; the success of a treatment which aims at sweeping out the intestinal tract and disinfecting it; chills and rigors preceding the rise of temperature, with alternating falls and sweating; and the periodic type of the disease with alternations of health and disease. We know that constipation and other bowel derangements will cause stagnation of bile with increased absorption into the blood, and that in this condition the constitution is more liable to disease than at any other time. We know also that by an energetic action by purgatives we can cleanse the *primæ viæ*, promote the natural passage of bile, and filter that already in the blood partly through the intestinal walls and by the kidneys. Now we know of no organism which fulfils part of its life history in the human blood which gives rise to such symptoms as are invariably found as a part of this disease, except perhaps dengue—but dengue is only malaria under another name—and relapsing fever, which bears a close relationship to it. Idiopathic cases of pyæmia are so like malaria that it is often impossible to distinguish them. But this only bears out the fact that malaria, like pyæmia, is an extraneous disease."

"If we grant the extraneous life of the parasite, then where is its place of development? Like pyæmia it must have a laboratory. I have no doubt that the laboratory is in the

intestines. It is also certain that the liver has an influence upon its development. Derangement of the biliary functions is always present before an attack. But such a condition can be observed before all diseases of the intestinal tract, showing the intimate relation between the liver and the *primæ viæ* and the tendency to inflammation spreading upwards to the liver. It is interesting to observe that LAUDER BRUNTON attributes some importance to the liver in connection with the arrest of certain substances absorbed from the alimentary tract whereby they are either destroyed, stored up, or it may be prevented from entering the general circulation in too large amount, and that ptomaines may be arrested in this way."

Further, the action of the liver, according to H. ROGERS, is dependent upon the presence in it of glycogen. Glycogen is a true carbohydrate and its mother substance is the carbohydrates of the food.

"It is increased by large quantities of starchy matters: milk, fruit, and cane sugar; it is diminished enormously by a purely albuminous or fatty diet, by forced muscular movements or fatigue, exposure to cold, by hunger or by anything which disorders the biliary functions."

"Now let us look at the conditions which induce malarial fever. They are identical with those which diminish glycogen—*e.g.*, purely albuminous or fatty food, fatigue, exposure to cold, hunger, or anything which tends to the formation of acid, a derangement of the biliary functions."

Directly there is an impotence in the diet whereby the glycogen is diminished, then the fever manifests itself. The effect of chills inducing an attack strengthens the hypothesis; for we know that in hot climates the glycolytic functions are profoundly affected by changes of temperature."

Briefly then, according to Dr. FORBES-LESLIE, malarial fever depends upon some organism or poison as yet unknown whose laboratory is the intestine.

In health, that is as long as the liver retains glycogen, the liver acts as a filter and prevents the poison or organism invading the system.

When the amount of glycogen is diminished, as it may be through several causes, the liver loses the power of arresting the poison or organism, which then passes into the blood and is the cause of the disease.

The treatment should, in the first place, be directed to clearing the offending matter out of the intestine; secondly, to destroying the poison already in the blood.

We think that to many who have studied malarial fevers clinically, Dr. FORBES-LESLIE'S views will be found to have much to recommend them.

HOSPITAL ABUSE IN AUSTRALIA.

DR. CHARLES P. B. CLUNBE made the following remarks on the subject in his Presidential address to the New South Wales branch of the British Medical Association:—

HOSPITAL ABUSE.

This country, like many others, suffers from, and has suffered from for many years, what is called hospital abuse. By this we may understand a misapplication of charity. Charitable institutions, that were originally founded for the relief of the sick poor, are now resorted to by all sorts and conditions of men. People perfectly well able to pay for medical advice on moderate terms now flock to these hospitals and receive the charity dispensed there without the slightest qualms of conscience, without feeling that they are doing any body any harm. They go with money in their hands, and they claim attention to their ailments as a right, quite forgetting that the very fact of their being able and willing to pay should at once and of itself debar them from receiving

charity. The people that abuse hospitals may be divided into five classes :—

First, those that are well off and go into hospital with the full determination of cheating the doctor. When these people are asked the ordinary questions as to their means, they probably say that they are not earning a pound a week. This may be actually true, but at the same time they may have several thousand pounds put by.

Second, the people that go to hospital because they do not consider they are recipients of charity at all. They would be quite indignant if you called them paupers. They always pay their way. They consider they pay for what they get. They do not consider for one moment they are cheating the doctors, because they fancy we are all paid for the services we render.

Third, the people who do not want to go to the hospital at all, would much rather be at home, but they are sent in by their medical attendant. The medical man has, perhaps, been attending for a few days, and then finds out or thinks that an operation is necessary.

Fourth, well-to-do people, who meet with accidents in the streets or elsewhere, and who are taken by the Civil Ambulance Brigade straight off to the nearest public hospital. Many of these cases should not go to a public hospital at all. If they cannot be taken home, they could easily be taken to one of the numerous private hospitals, and their own medical man could be sent for.

Fifth, careful people with limited incomes, not by any means paupers—persons who would willingly pay a small fee for advice but are quite unable to afford the usual fee charged by the general practitioner.

Dr. CLUBBE shows that the usual fees charged by practitioners is higher than the majority of the people can afford to pay, viz., 10s. 6d. As an important measure of reform he advocates lower fees to the poorer classes.

The remedy according to Dr. FREDERICK HOLME WIGGIN, New York —

In my opinion, the first step which should be taken towards remedying the existing abuse, is an effort to educate the laity to believe that medical professional services have a pecuniary value, and that it is morally wrong for those able to pay, even a moderate fee to try to get this service for nothing. It should be thoroughly understood that people of means applying for free treatment at dispensaries intended for poor persons, practically rob the poor by taking up the physician's time that should be devoted to the poor—those for whom alone these institutions were intended. It would be a great aid in this direction if physicians connected with charitable institutions were paid for their services. There certainly appears to be every reason why they should, and none why they should not be compensated.

In the second place, all institutions which dispense medical charity should be placed under the direct care and supervision of State boards of charities, created by legal enactment, if they do not already exist, which should have the power to grant incorporation or licences to such institutions as the public interests seem to require, and to make such rules and regulations for their guidance as they consider proper.

THE BACTERIOLOGICAL PAD PUNCTURED.

THE *Medical Brief*, under the above somewhat sensational heading, discusses certain views which have been expressed on the subject of bacteria by Dr. HENRICH GIBBS, the well-known London bacteriologist :—

"Concerning bacteria as a factor in the causation of disease, Dr. GIBBS," we learn "made his position very clear. While recognising their existence and possible influence, he

denies their importance as a causative factor of disease."

"Conceding to Dr. KOCH, the discovery of the tubercle bacillus and the bacillus of cholera, he denies that in either instance has the etiological influence been demonstrated."

But who is Dr. GIBBS? the reader will naturally ask. Well, here is the answer, and it must be admitted that no objection can be taken to his views on the score of incompetence.

When the University of Michigan, some ten years ago, cast about to secure a man for the chair of bacteriology in the medical department, who stood at the head of his profession in this respect, it scrutinized the records of many men whose names are as household words in science, and finally selected Dr. HENRICH GIBBS, then of London, as the man best fitted for the place. Dr. GIBBS was at that time justly regarded throughout learned Europe, and by those in America cognisant of his attainments, as an authority in questions involving pathology and bacteriology, in its relations to the etiology of disease.

The London *Medical Press* reports Dr. KOCH, of Berlin, as saying, "With the departure of Dr. GIBBS for America, England loses one of its foremost bacteriologists." Sir JAMES PAGET, one of England's greatest surgeons, pronounced Dr. GIBBS "one of the most active and successful workers in modern pathology and bacteriology."

His denial, therefore, that the bacteria is the causative factor in disease is not based upon mere opinion, but on actual experiments. So convinced is he of the non-causative nature of the so-called pathogenetic bacteria, that he has time and again inoculated himself with bacteria without experiencing the slightest evil effect.

"The idea," says he, "that we must dodge a *Klebs-Löffler* bacillus here, to escape diphtheria; a bacillus tuberculosis there, to escape consumption, or a comma bacillus to evade cholera, etc., is a mere fad, nothing more nor less." He denies, too, even the fact, hitherto urged as a proof of their etiological nature, that these pathogenetic micro-organisms are always present in certain diseases. He declares that he has conducted hundreds of autopsies on consumptives without finding a trace of bacillus tuberculosis. Speaking on this point, he gives the following rational account of its origin: "A young woman gets wet feet; she takes cold, acquires bronchitis—capillary bronchitis. This terminates in pneumonia and runs into consumption, which finally causes death. Where does the bacillus come in? You will not find a germ in her lung, either." In short, his practical investigations have convinced him that the whole germ theory of disease is a mere theory, or, to use his own term, "a fad."

While admitting, and paying tribute to the learning of Germany, which he declares is universal, he denies the claims of superiority of "German science." "There is no such thing," he exclaims, "as German science—science is universal." "The Mecca," he continues, "of the American physician is Berlin; nothing good can come from any other source than Germany in the science of medicine as taught in American schools. The admiration of German scientists is nothing short of idolatry. In Germany, Dr. KOCH's theories are generally regarded as *theories*; in this country they are held to be *facts*. I taught along the lines of KOCH, but presented results only for what they were worth."

THE BACILLI OF BERI-BERI.

THE following interesting note on the bacilli of beri-beri by M. GUSTAVE NERNST (*Comptes Rendus*), was presented to the French Academy of Science on the 17th January 1898 :—

"The morphological characters of the bacilli of beri-beri are quite distinct; so that, in spite of the absence of cul-

ture and of experimental proof—specimens which can only be carried out with fresh liquids in the tubes where the disease arises—I believe I am entitled to say that the bacillus I am about to describe is the true specific bacillus of typhoid.

"The anatomical specimens which have provided materials for this research all came from Bengal and were taken under the most favorable conditions.

"Three different forms of bacilli were found in buri-beri, etc., large, medium sized and small.

"The large bacillus is occasionally, but rarely, found in the vessels together with the other forms, its seat of election is the kidney; there it may be seen either alone or in groups in the cavity of the glomeruli, within the convoluted tubes or in the loop of Henle, less frequently in the straight tubes; their length is 6 μ , 7 μ , 8 μ , 9 μ , 10 μ ; their width from 0.8 μ to 0.6 μ ; they are straight or slightly curved; their ends are ovoid and always of a dark color; clear and dark colored spaces alternate to the number of 5, 6, 8, etc., in the largest bacilli, a very fine bordering line surrounds the bacillus.

"The best means of demonstrating the large bacillus is to stain sections of the kidney (par un bain d'alun d'ammoniaque et de sesquioxyle de fer au 100 \times , de le surcolorer au bleu de Roux et de les décolorer avec force) in a solution of alum, ammonia and sesquioxide of iron to 100 \times , to counter stain with Roux's blue and to decolorise sufficiently; the dark parts remain blue, while the remainder with the surrounding line are stained a delicate rose color.

The medium bacillus is much smaller, 8 μ to 4 μ at most in length and about 0.3 μ in breadth, like the preceding it has alternate dark and clear spaces, it is found in large quantities in certain vessels, in the small veins, capillaries, and arterioles of the kidney, so numerous are they that they present the appearance of a thick muddy liquid and from their abundance they would be difficult to describe if their characters were not emphasised by strong staining with fuchsin and methylene blue.

"By this means the elements of the dense mass can be recognised.

"The small bacillus is very small and exists in considerable numbers in the blood, they are scarcely as broad as tubercle bacilli, but their length is hardly double their breadth; their general appearance is that of a small rectangle. They can be distinguished with a 140 objective and a No. 12 Zeiss-eye piece. They are scattered over the surface of the red corpuscles and around their circumference, giving to them a crenulate appearance.

"Are these three forms of bacilli distinct? The large and medium appear to me to be of the same nature and to be analogous to the bacilli of fowl cholera and of rabbit septicaemia. Considering the extreme minuteness of the small bacillus I cannot affirm that the others are derived from it, though I think it probable. The medium and small forms are found in the blood of all the organs: spleen, kidneys, liver, spinal marrow, etc."

THE SPREAD OF ENTERIC FEVER.

THE Public Health Engineer says:—"Dr. JOHN BROWNLEE, of Belvedere Fever Hospital, recently read a paper to the members of the Philosophical Society of Glasgow entitled, 'Observations on the aerial transmission of the enteric fever poison, with a record of an outbreak presumably caused by this means of infection.' He alluded at the outset to the revolution in the method of approach brought about by the discovery of the enteric fever bacillus in 1880,

and spoke of the experiments and investigations of Dr. ROBERTSON, of Sheffield, and Dr. EQUINA, of Egypt. The former had found that the bacillus would live a considerable time in ordinary arable land, while Dr. EQUINA said that enteric fever was spread by dust among the soldiers in the Egyptian campaign of 1885. He described an experiment which he himself had made, by which he found that the bacillus could live in ordinary dust, because dust always contained a small amount of moisture. He then gave an account of an epidemic in the city of Glasgow fever hospital in Kennedy Street. There had been a number of enteric patients, and some time later, when the drains were upturned for repair, a number of cases occurred all over the hospital. He believed these to have been due to aerial transmission of bacilli. Dr. BROWNLEE's conclusions were:—(1) That more especially in large towns all back courts should be provided with an impervious pavement; earth or causeway being open to organic fouling; (2) they ought to be carefully scavenged by the plentiful use of water; (3) wet asphalt is extremely objectionable, and should not be tolerated, for not only do they provide a fertile soil for propagation of the bacillus, but their cleansing may be a new source of the disease both by aerial contamination and also by conveyance of the bacilli to new and possibly unpolluted localities. A series of sporadic cases might readily occur in the district without any apparent connection among themselves, yet which, if our knowledge of the train of associated circumstances were complete, might be traced back to a common source of infection."

A MEDICAL SAVANT'S OPINION ON THE SO-CALLED CALCUTTA PLAGUE.

DR. MAHENDRA LAL SINGAR, M.D., D.L., C.I.E., one of the oldest and most respected physicians of Calcutta, writes as follows of the so-called Calcutta plague:—

"The Municipality has been busily reporting case after case, as occurring here and there in Calcutta, and up to the 30th of this month (May) 76 cases and 37 deaths have been reported. Some of these cases, which had come under the observation of watchful men, were challenged and proved to be cases of ordinary fever or even other diseases than fever, but we do not see that the Municipality has taken care to make the necessary corrections in their returns. If it was the object of the Municipality to swell the numbers of the plague cases or the so-called plague cases in order to show that Calcutta was really plague-stricken, it could not have adopted a better plan.

"It is fact that medical opinion is not unanimous on the real nature of the cases that have been reported as cases of plague. The oldest and the most experienced practitioners of the city are decided in opinion that the cases are not new to them, that they have been observing and treating such cases ever since they have commenced to practice. With all deference to the high medical authorities who have pronounced plague in Calcutta, we are inclined to hope that the real disease has not yet made its appearance in our city; or if it has, it has come shorn of its infective virulence."

Dr. SINGAR shoulders the full responsibility of the above quotation, which we take from the *Calcutta Journal of Medicine*. We endorse every word of the above protest, but we raise an objection to the initial paragraph. The Municipality cannot be fettered with the influence of the Bengal Government. Let us nail the charge on the right action board, and blame the unethical Plague Commission, for the follies that have resulted in a reign of terror and lawlessness in the city.

IMPROVEMENT IN BOMBAY SANITARY ADMINISTRATION.

SURGEON-INSPECTANT-COLONEL CLARKSON offers the following suggestions in the Bombay Sanitary Report:—"The time has now come to add to the Sanitary Department the nucleus of an establishment which, while strengthening it, will also enable it to impart instruction," and he urges that an establishment might be formed on similar lines to the Sanitary Institute of Great Britain. The extra staff would include a bacteriologist, and the scheme contemplates the acquisition of a building large enough to accommodate the establishments of the Sanitary Commissioner and Sanitary Engineer, the bacteriological and chemical laboratory, and a combined lecture-hall and show-room for sanitary exhibits. Courses of lectures would be given to medical men, and to persons desiring to qualify as *maitres* or native supervisors, and examinations would be held and certificates granted. It is suggested that the District Municipal Act should be amended so as to preclude the appointment after a certain date, of health officers and inspectors who have not obtained certificates of qualification. Dr. CLARKSON's scheme is undoubtedly the most practical suggestion which has yet been brought forward to obtain an improvement in mofassil sanitation. If it is carried into effect, it ought to ensure a permanent supply of men trained in the principles of sanitary work. Only by some such means will it be possible to bring about sanitary progress in Western India. We heartily endorse his further recommendation that municipalities "should not be allowed without the sanction of an independent body (say the Sanitary Board), to dismiss or curtail the pay of their health officers and sanitary or health inspectors, or any superior servant who does sanitary duty." This principle already obtains in England, where municipal servants of the higher grades have a right of appeal to the Local Government Board, which in some respects performs duties corresponding to those undertaken by the Bombay Sanitary Board. The Bombay Government has hitherto been reprehensibly neglectful of some classes of municipal servants. Had proper supervision been exercised over the relations of municipalities and their employes, the grievances of the European sub-inspectors in the Health Department, of the Bombay Municipality, who are scandalously underpaid, would long since have been remedied."

LEGISLATION AS A REMEDY FOR MEDICAL GRIEVANCES.

A BATTLE-ROYAL is being waged by Drs. R. BRUDENELL CARTER and VICTOR HOMERLEY on an issue arising at the last meeting of the General Medical Council from a demand by the Executive Committee to register three unqualified dentists by the ambiguous rulings of section 37 of the Dentists' Act, and the medical press has taken sides with their respective champions.

In order to secure a larger proportion of the fees and fines for qualified practitioners and protect their incomes from the attacks of prescribing chemists, foreign doctors, quacks and such like unregistered persons, Mr. VICTOR HOMERLEY (*Clinical Journal*) gave a public lecture on 12th December 1897 at which, among other things, he insisted that registration was the only qualification to practice medicine, surgery and midwifery, and that if the (Medical) Acts of Parliament meant anything at all, they meant that the man who was not registered was not entitled to practice.

Rightly or wrongly, we cannot say, as Mr. HOMERLEY's speech is not published in extenso, but Mr. R. BRUDENELL CARTER, M.B.C.S. (*Medical Times and Hospital Gazette*) con-

tends that Mr. HOMERLEY was prompted by unkind feelings to attack him personally and based his deductions on the position of a "comma" he found in a printed copy of the Medical Act; but forgot or did not know that "there are no stops in an Act of Parliament. He spoke of his own career as a practitioner long years before Mr. HOMERLEY was born, and showed an unbroken record of 40 years in higher medical journalism. He brought non-controvertible *de masses* to prove that the Medical Acts neither afforded the profession protection against unregistered practice nor rendered it compulsory for every qualified person to register, nor could prevent a qualified man continuing to practice after his name had been erased from the Medical Register, nor even had power to prevent unqualified persons from practising, so long as they used no titular initials to deceive the public. He admitted he was dead against counter-prescribing, patent medicines and unqualified practice, but regretted that quackery must continue so long as the British Medical Association derived a large portion of its income from the advertisements of quack medicines.

HEALTH OF BOMBAY.

STATISTICS for the week ending 31st June show that the health of Bombay has been completely restored.

The total mortality was 448 or 88 below the five years' average. The plague has declined in a remarkable manner, as the following table shows. It is hoped that in another month the city will be quite free from disease:—

DEATHS FROM PLAGUE.

Week ending 17th May	109
24th "	101
31st "	84
7th June	44
14th "	26
21st "	15

It is noted that the districts of Mandvi and Cammattee-poor, which were the first districts attacked during both our plague visitations, are the last districts to shake off the disease. There must be something radically wrong in these districts.

All the most important and chiefly fatal diseases are showing a continuous decline. The following table exhibits the decline of the last six weeks:—

WEEK ENDING	17th May.	24th May.	31st May.	7th June.	14th June.	21st June.
Menses	4	3	...	8	5	2
Small-pox	2	1
Cholera	4	1	...	1
Fever	58	57	55	74	65	62
Phthisis	86	87	65	83	90	87
Respiratory diseases	116	125	119	89	107	95
Plague	107	101	84	44	26	15

Relapsing fever continues to be unduly prevalent. The following gives mortality from the disease during the last six weeks:—

Week ending 17th May	4
24th "	3
31st "	12
7th June	6
14th "	5
21st "	9

SEWER VENTILATION.

It has unfortunately fallen to the lot of the majority of sanitary authorities to be troubled from time to time with the incursions of evil smelling sewers and the complaints which they naturally give rise to, and many devices and much ingenuity have been invoked to get rid of the evil. Tall ventilating shafts appeared at one time to be considered the universal panacea, and at some fashionable resorts it was custom-

ary to construct these shafts in all sort of fancy and fantastic shapes, such as trees, telegraph poles and flag staff, so as to conceal their true nature from the visitor who might otherwise have been frightened away.

According to a pamphlet entitled "The Sanitary Problem from the Sewer Gas Point of View" by Mr. WILLIAM BROWN, reprinted from the *Public Health Engineer*, these high ventilating shafts are altogether to be condemned as a fallacy.

He points out that as the decomposition of sewage is the cause of sewer-gas, this gas can readily be neutralised if a sufficient quantity of pure atmospheric air is allowed to mix with it as it forms, i.e., sufficient to produce natural oxidation; in his opinion a system of gratings level with and in the middle of the street is the best means of effecting this oxidation.

Sewer gas means an imperfectly ventilated sewer, and Mr. BROWN insists that "so long as sufficient fresh air goes down these gratings, the sewer air remains sweet. The essential thing, therefore, in sewer ventilation is to get the fresh air down not to get bad air up. In a properly ventilated sewer there should be no bad air to come up."

Mr. BROWN's system is conveyed in the following sentence:—"Free natural oxidation to the utmost possible, with auxiliary artificial oxidation whenever necessary." He maintains that the result is obtained by the Reves system, which is working at Sutton, Epsom, Edinburgh and Fulham and elsewhere.

LIMITS OF PROFESSIONAL SECRECY.

SAYS *The Lancet*:—"Mr. E. A. BARTON, in a letter under this title in our issue of 7th May, stated a situation which has often caused difficulty to medical men, who will be grateful to him for having ventilated the subject. We are of opinion that in a general sense, if a medical practitioner is engaged by an employer to professionally attend an employé, he ought not to divulge to such employer the nature of the illness of the patient. Of course he should exercise his discretion in the matter. There could be no harm done if the illness were of a simple nature—simple, that is to say, as regards its bearings beyond its medical aspect. We can imagine circumstances which might render it wise and obligatory on the medical practitioner to inform the employer of the nature of the servant's ailment—e.g., in a case of infectious disease. We do not think an employé would recover damages from a medical man for making known his complaint, provided always that the facts could be substantiated and that they were communicated without malice. There could not be a valid contract between the employer (who pays for) and the attending practitioner except as to attendance and remuneration. It is no part of a medical man's duty to act as a secret police agent. We should advise him to inform the employer that he should consider any information he might obtain in his professional capacity as strictly private between himself and the patient and not to be divulged except with the free consent of the latter. We consider that secondary syphilis, for the purposes of the argument, should be classed as an "infectious disease," since through ignorance, negligence, or inadvertence it might be conveyed to other members of the household. Pregnancy or disease arising from alcoholism ought not to be divulged to the employer without the consent of the servant."

SURGEON-CAPTAIN HORTON SCOTT, A.M.S.

SAYS the *British Medical Journal*:—"This officer, who was, as our readers know, severely wounded in action in West Africa, is, we are glad to hear, making some progress towards recovery in St. Thomas's Hospital. What is not so well known is the fact that, like his distin-

guished brother officer at Majuba Hill, ~~Mr. Scott~~ his left femur was smashed by a heavy slug, and another ~~bullet~~ of a like formidable kind had torn his chest without violent penetration, he stuck to his duty, and while prostrate on a stretcher and severely tortured by his wounds, he continued to give surgical aid to his wounded comrades. We have seen an extract from a letter of his to his family, written from the hospital in Sierra Leone, in which he thus modestly refers to his brave conduct on the above occasion: "Six reserve men of the M. S., including Corporal FROST, of Portsmouth, came to see me. Really kind of them, was it not? They were all full of the fact that I kept on doing duty after being hit. It was the least one could do to help them, as I was the only medico. I thought nothing of it, but DOWMAN also spoke so warmly about it." If the Secretary for War needed any justification for the full measure of justice extended to the medical staff of the Army, Surgeon-Captain HORTON SCOTT, like his brother officer on Majuba Hill, has supplied it; both, by their bright example, inspiring their brethren when on the path of duty how "to suffer and to die."

STRAITS SETTLEMENTS BRANCH OF THE INDIAN MEDICAL ASSOCIATION.

THE monthly meeting of the Straits Settlements Branch of the Indian Medical Association was held on the 27th May 1898, the following members were present.—Messrs. A. B. LEICESTER, W. B. ANGUS, H. J. GIBBS, A. A. HALE, J. V. PESTANA.

Mr. BYLANDS, of the Johore Medical Service, attended as a visitor. Messrs. REARDON and AERIA wrote regretting their inability to attend.

The minutes of the previous meeting were read and confirmed. Mr. REARDON's proposals seconded by Mr. ANGUS that the members meet on a Saturday afternoon instead of after dinner was negatived by the majority of the members present. Mr. GIBBS's proposal seconded by Mr. HALE that the Bonus Memorial be taken in hand at once was unanimously agreed to. Mr. GIBBS (the Honorary Secretary) then read his paper on the staining of bacteria, the preparation of nutritive media and a few remarks on the great aid of the microscope in diagnosing diseases for which he was accorded a vote of thanks.

Question papers were next set the members by Messrs. LEICESTER, REARDON and GIBBS on the management of natural labor and the puerperal state; on cholera and plague; and on dislocations of the shoulder joint.

A vote of thanks to the Chairman (Mr. A. B. LEICESTER) concluded the meeting.

MESSAGE IN INFANTILE PARALYSIS

SURGEON-LIEUTENANT-COLONEL W. A. LEE, I. M. S., of Tanjore, is to be congratulated on having made a move to try and mitigate the effects of infantile paralysis, and to introduce some method into the after-treatment of the disease.

He has drawn up an admirable series of simple "Directions to Mothers Respecting Paralysed Children," which are printed both in English and in the vernacular, at the "Poornachandrodaya Press," Tanjore.

In an accompanying "Note" he comments upon the usually unsatisfactory nature of the treatment which at best can be given to these cases when they are brought to the out-patient departments of hospitals.

He says that "the effect of systematic exercises of the muscles is to cause increased afflux of blood to the cord, thereby improving its nutrition and causing compensatory enlargement of the still healthy ganglionic cells in the neighbourhood of the degenerated ones."

Surgeon-Colonel Linn's directions consist of simple rules for massage rubbing and bathing of the affected limbs, they are concise and easy to understand; and we hope that the out-patients of the Raja Mirasdar Hospital, Tanjore, and of other places, may learn to make use of and to profit by them.

M. ZAMBACO ON LEPROSY

A WORK by M. ZAMBACO entitled "Les lépreux ambulants de Constantinople" (The Walking Lepers of Constantinople) has been awarded the prize for the advance of chemical medicine by the French Academy of Sciences.

M. ZAMBACO, in the *Comptes Rendus*, has given a description of leprosy in all its forms, he has added new features to the classical delineation of the disease and the accuracy of his clinical pictures enables the diagnosis to be made from the objective signs, even when the bacteriological examination proves negative, in the same way that lupus can with certainty be declared tubercular, though KOCH's bacillus is not found.

M. ZAMBACO has good reasons for believing that certain erythemas are leprosy, as Morphea, Scleroderma, Ainhum, Syringomyelia, even though HANSEN's bacillus has not been demonstrated. He has proved the existence of infantile leprosy, and brings forward decisive arguments in favor of the hereditary nature of the disease.

Comparing a mutilating disease observed in Brittany with his observations on leprosy in Constantinople, he concludes that leprosy and MORVAN's disease are identical, and guided by the accuracy of his clinical observations, he visited Brittany and discovered an endemic leprosy there.

THE ANTI-OPIMUM CRUSADE IN INDIA.

MR J. G. ALEXANDER moved the following resolution at the last meeting of the British Anti-Opium Society —

"The following missionaries and other foreign residents who have, by addresses when in this country, by their writings, and in other ways rendered essential service to the Anti Opium movement, are hereby appointed (subject to their consent,) as corresponding members of the Executive Committee, with the right to attend and take part in its sittings when in England, and the Executive Committee is authorised from time to time to add other names to the list subject to confirmation at the next annual meeting of the Society.

"India — DONALD MORISON, M.D., English Presbyterian Mission, Rampur Boalia, Rev COLIN S. VALENTINE, B.Sc. LL.D., Edinburgh Medical Mission, Agra, Rev W. RAJU, Methodist Episcopal Mission, Madras, Miss SOONDERBAI POWAR, Home for Indian Widows, Poona, Rev BISHOP THOBURN, D.D., Methodist Episcopal Mission, Calcutta, RAI LAL MADHUB MOOKERJEE, Bahadur, L.M.S., President of the Calcutta Medical School.

MATERNAL IMPRESSIONS

MARTIN relates the following case — "A man was shot through the chest, the bullet emerging in front in the intercostal space between the fourth and fifth ribs. His wife was near, and in rendering assistance she got her hands and face covered with blood. She was approximately fifty days pregnant, and was much agitated by the conviction that the child would be born with a 'bloody face.' After confinement she brought her baby, saying that it had not got a bloody face, but that it had the holes where the ball went through her husband's breast. On examination there were no holes, but there were bright red marks, consisting of elevated oval and bright carmine spots, very near, though not identical with the location of the wound on the father's chest. The mother had seen the wounds during her husband's illness, and they made her feel sick every time she looked at them."

THE AMERICAN SPANISH WAR.

THE *Philadelphia Medical Journal* says:—"War, the brute's method of settling disputes, is upon us. Hundreds of millions of dollars are eagerly voted to destroy property, create disease, mangle and kill human beings, and if one-hundredth or one-thousandth of this amount were asked of our jingo political bosses for preventing disease and death, the request would be laughed at. How far are we from rationality, religion, or true civilization? Physicians, we are glad to know, will still pursue their noble vocation of lessening and repairing the evil as much as they may. Everywhere they are offering their services—we hope in their professional character—to prevent disease if possible, at least to cure it, and, in the last resort to save what of life and limb may yet be possible. The progress in medical and hygienic science has served to make the barbarism and degradation of war less horrible, and we may be sure that the humanity and science of our calling will be felt in mitigation of the pitiable evil and injustice."

TO MY ANTI

We quote the following from the *New York Medical Record* —

'What cures my head when full of aches,
All joy my racking brain forsakes,
And all life's pleasures seem but 'fakes'!

My Anti

What cools me when I feel as hot
As Dives when below he'd got
And envies Lævatus happy lot?

My Anti

What helps me when I have the fits,
And every one who round me sits
Immediately gets up and 'gits'?

My Anti

What fills the German chemist's purse,
And incidentally perhaps the hearse?
What always terminates my verse?

My Anti

PRESCRIBING CHEMISTS. LAWFUL AND UNLAWFUL

THE *Chemist and Druggist* responds to a query as follows:—"If a customer states his symptoms and you decide on and supply the remedy, you are acting as an apothecary, and are liable accordingly, whether the remedy supplied is a proprietary article or not. But if you advertise the remedy and the customer himself fits it to his symptoms you are not liable to any action." This is an accurate statement of the law, but we should very much like to know how many chemists keep within the law in this respect. Prescribing by chemists has become quite universal, and it is high time that steps were taken to exact penalties from a few notorious offenders. The fact is that the medical profession has allowed its rights and privileges to be encroached upon by every body in the past, and there will be need of very vigorous measures now if these privileges are to be retained."

FIRST CARE OF A BABY.

HARON (*Cleveland Med Gazette*) is one of those who believe that the baby who is started right stands a much better chance to grow up well and strong than if allowed to catch cold or get indigestion within the first few hours of life. He insists upon the following simple rules as being all important: (1) Do not expose the baby after birth to a greater change of temperature than is absolutely necessary. (2) Do not allow attendants to subject him to prolonged exposure while washing, but rub him over with lard (this usually being convenient), and quickly wipe him off and

wrap him up warmly. (3) Do not use too fine a thread in tying the cord, and dress the same with dry, sterile dressing. (4) Give nothing but tepid water or some very weak aromatic tea until there is sufficient milk in the mother's breast for the child's requirements. (5) Notice the clothing and see that the abdomen and chest are not constricted thereby.

DR. GAUCHER ON KIDNEY DISEASE

M. LE DR. GAUCHER (*Comptes Rendus*) in his work on the pathogeny of epithelial nephritis, has demonstrated experimentally the toxic origin of this ailment by the subcutaneous injection of animals with extractives such as leucine, tyrosine, creatine, creatinine, xanthine, hypoxanthine. From these experiments he deduces the pathogenic rôle that matters due to mal-nutrition exercise in the kidney, and he shows more loudly, than it has ever been done before, the great importance of diet in the treatment of kidney disease, according as matters are introduced into the system which have an injurious effect on the kidney or the reverse.

THE MAN NOT THE DIPLOMA.

SAYS the *Medical Record* — Dr. PLAYFAIR, in a lecture on the program of obstetrics and gynecology, made the following pertinent remarks: 'A man's skill as an operator depends on his brains and on his fingers, not on the letters he writes after his name. I know fellows of the College of Surgeons whom I would not trust to vaccinate a baby, and I know fellows of the College of Physicians to whom I would unhesitatingly confide any operation they chose to undertake, and, *per contra*, if I were asked to select an obstetric physician to a hospital between a man who was an M.D. and F.R.C.P. Lond, whom I knew to be an inferior man, and a man who was a simple M.B.C.S. whom I knew to be a superior man, I would certainly select the better man of the two, irrespective of his qualifications.'

SURGEON-CAPTAIN GRAYFOOT, I.M.S.

SURGEON-CAPTAIN W. B. GRAYFOOT, I.M.S. who has for the past nine years filled the important office of Secretary to the Surgeon-General to the Government of Bombay, has by the impartial and able manner in which he has conducted his very onerous duties, earned the esteem of the whole of the members of the Bombay Medical Services, with whom he is deservedly popular. The Civil and Military branches of Assistant Surgeons and Hospital Assistants have much to thank Dr. GRAYFOOT for his urbanity and fair dealing, and we take this opportunity to express the gratitude of these classes to Surgeon Captain GRAYFOOT for all he has done for them.

IMPLICIT CONFIDENCE. INDIA TO THE FORE

THE Hyderabad *Chronicle* says that when the time came for decision as to who was to perform the operation necessary to Dr. LAWRIN's fractured limb, Dr. LAWRIN, though surrounded by medical men of various grades and qualifications, selected Dr. ABDUL HUSAIN, the House Surgeon of the Ahsalganj Hospital, and entrusted his case to that gentleman's care and supervision. "We do not think," remarks our Hyderabad contemporary, "that a greater tribute could have been paid to the skill of Dr. ABDUL HUSAIN, and bearing in mind that the knowledge acquired by him has been purely local and only under Dr. LAWRIN's tuition, the circumstance is alike creditable to master and pupil."

ANGLO-INDIAN SUCCESSORS

AT the 1896-97 session examination for the admission of candidates to the Engineer and Telegraph classes of the Thomason College, Roorkie, 14 Anglo-Indians, and 5 Indians passed successfully—Terence Bradley, Joseph Smith and Herbert Chestney, all Lucknow Martinjere boys, took the

first three places on the list. The first of the Anglo-Indians hail from the Lucknow Martinjere. Ernest A. Scott was the Don of the year 1896 at Roorkie. He won all the medals and the India Council Medal of Rs. 1,000. At the closing Roorkie session, the Don was J. B. Smith, the winner of the Thomason Gold Medal for the best engineering design, while Terence Bradley gained the Higher certificate and the India Council Prize of Rs. 1,000. Both hail from Lucknow Martinjere.

A PROBABLE CAUSE OF ENTERIC AT MEERUT.

THE *Morning Post* says — "A startling discovery that may account for the presence of enteric among the troops has been made at Meerut. A surprise visit made to the dairy of the 5th Dragoon Guards by the medical authorities disclosed the fact that the cows were feeding upon bores with which stable refuse and other abominations had been freely mixed. Experiments with the milk for eight days subsequently showed that it was highly dangerous for human consumption, and it was all destroyed. It is small wonder that we have enteric in India, if this sort of thing is possible in every station."

THE INDIAN MEDICAL SERVICES IN PARLIAMENT.

CAPTAIN NORTON asked the Secretary for India when it was proposed to amend the Indian Medical Regulations, so as to insure that officers of the Indian Medical Service, who have no previous military experience, or at all events have not any lengthened period of experience in military duties, shall be made to pass a longer period for military medical training than two months in the office of a principal medical officer prior to being selected for promotion to administrative grade; whether any changes, and, if so, what changes in this respect had been proposed or recommended; and when they would be promulgated. — Lord GEORGE HAMILTON said he was not aware of any proposals at present before the Indian Government to amend the Indian Medical Regulation in regard to the training of medical officers selected for promotion to the administrative grade.

TREATMENT OF UTERINE MYOMATA BY REMOVAL OF THE OVARY

M. HOFMOEL (*La Semaine Médicale*) showed a woman, about 50 years of age, who had a myoma of the uterus so large that it could not be extirpated. The right ovary was removed, the left could not be found. Since then the uterine tumor has diminished greatly in size, the intestinal and vesical troubles have disappeared, and the patient feels very well. The author has seen another similar case, and in a case published by M. YON, MOERSTIG-MOORHOFF a simple laparotomy had the effect of reducing the size of the tumor to a considerable extent.

THE ANGLO-INDIAN CAUSE

THE *Mefasinte* of Musoorie says — "We gladly announce the welcome news that the first Anglo-Indian Conference will shortly be held in Musoorie, and delegates are invited from all parts of India to represent their different Associations and branches. At the last meeting of the Imperial Anglo-Indian Association at Calcutta it was unanimously resolved that Dr. JAMES B. WALLACE, M.D., F.R.C.S., the sturdy champion and able advocate of this cause, represent that august body in Musoorie. We can promise him a sitting and cordial reception from our people here."

A CASE OF PLAGUE INFECTION

SAYS the *Indian Daily News* — "A most instructive lesson is to be learnt in connection with the case of plague in British Indian Street, in which the sufferer was a European. We give the story as told us. Some time ago, a dog belonging to the patient brought up into his bed-room a rat it had killed and plumped it down upon the floor. His master at once threw the rat away. The dog then licked his master's hand on which there was a slight abrasion, with the result that plague showed itself a few days after. If this story is true, it means that people must put themselves on their guard as far as their household pets are concerned."

SHORT ITEMS.

Among some of the measures that Brockey Smith has found useful in his surgical practice are mentioned: The prevention vomiting after an operation by placing a cloth wet with vinegar over the face or by spraying the nares with cocaine for the relief of abdominal pain after celiotomy teaspoonful doses of hot water may be given, and hot water applied to the abdomen when this can be done without infecting the wound; to prevent the extreme thirst that follows operation the patient should drink water freely for three or four days before operation.

Marriage, according to Dr. Schwartz, of Berlin, is the most important factor in longevity. Of every 200 persons who reach the age of forty years, 125 are married and 75 unmarried. At sixty years the proportions are 48 to 22; at seventy years, 27 to 11; and at ninety years, 9 to 3. Fifty centenarians had all been married. The doctor asserts that the rate of mortality for husbands and wives between the ages of thirty and forty-five years is sixteen per cent., while that for unmarried persons is twenty-eight per cent.

"Personal Reminiscences of Syme" by Dr. Maclean, which appeared in the *Record*, was originally contributed to the *Medical Age* and has since been reproduced in other journals. We acknowledge with pleasure and thankfulness our indebtedness to Dr. F. W. Mann, M.D., Detroit, U.S.A., the able Editor of the *Medical Age*, for his kind courtesy in permitting us to use the article in question, which has interested so many in India and Burmah.

The *Bengal Times* writes:—"If, then, plague has not reached Calcutta, Dr. Wallace has anticipated experience by revealing that fact, and by his revelation, calming and soothing fear and irritation. For this service alone, he has become entitled to public gratitude and to a recognition by Government, than which we can scarcely picture to our fancy a more gratifying appreciation. Public distinction has been conferred for services far less valuable."

The College of Physicians of Philadelphia announces through its committee that the sum of 500 dollars (£100) will be awarded to the author of the best essay in competition for the First Nathan Lewis Hatfield Prize for original research in medicine. The subject proposed is "A Pathological and Clinical Study of the Thyroid Gland and its Relations. The competition is open to members of the medical profession and men of science in the United States.

Dr. Solomons, the Government Medical Officer of Anaradhapura, Ceylon, had been reported by a Mr. Bell for strange conduct, in that, when professionally summoned by Mrs. Bell one night, he had turned up in *deshabille* and in an unfit condition. The *Times of Ceylon* learns that Dr. Solomons has been recommended for dismissal by the P. M. O., his explanation not being considered satisfactory.

Dr. Hayman Thornhill, whose article on "*Anchylostoma Duodenale*" appeared in our 16th June number, desires us to state that his original article was published in the "Transactions of the Indian Medical Congress." It was from that volume that our epitome of Dr. Thornhill's article was made. The original was too lengthy, and we have in our epitome dwelt on such points as we thought most essential for scientific publication.

Dr. Sarat Mullick has been re-elected to the post of Resident Medical Officer to the London National Hospital for Diseases of the Heart and Paralysis. At the last meeting of the Board of Governors Dr. Mullick was cordially thanked for the ability with which he had performed his duties, and it was mentioned that this was the first occasion on which such a re-election had been made.

Surgeon-Colonel Stephen, P. M. O. in Assam, will officiate as Inspector-General, Civil Hospitals, in the Punjab, vice Surgeon-Colonel Rye, who takes leave on the 10th of August for eight months preparatory to retirement. Brigade-Surgeon Lieutenant-Colonel Oalthrop, now on leave, will probably be appointed to Assam. It is believed Surgeon-Colonel Franklin will get the Punjab after Dr. Stephen has officiated there.

Surgeon-Colonel J. Sanderson, A.M.S., P. M. O., Line of Communication, Tirah Expeditionary Force, in recommending and forwarding for favor of transmission to the Political Department, Government of India, the application of Military Assistant Surgeon W. C. McMillan for an appointment in the Political Department, says:—"This Warrant Medical Officer will be of much use politically, having mastered six Oriental languages and also medically in the Foreign Department."

A Government enquiry is to be held as to the causes which have led to the existing prevalence of enteric fever at Utacumund. Surgeon-Major H. Thomson, Assistant Sanitary Commissioner, Madras, is engaged in the investigations. Much discussion has taken place as to the true cause, very widely divergent opinions being held, and by some Government is blamed for having lowered the level of the lake.

The annual meeting of the Brussels Medical Graduates, Association took place at the Cafe Royal, Regent Street, London, W., on Tuesday, 12th July, at 6.30 P.M., and was followed by the annual dinner at 7.30 P.M. Any Brussels medical graduate desiring to be present at such meetings should communicate with the Honorary Secretary, Dr. Major Greenwood, 248 Hackney Road, London, N. E.

It is estimated that only 900 persons out of 1,000,000 die from old age, while 1,200 succumb to gout, 18,400 to measles 2,700 to apoplexy, 7,000 to erysipelas, 7,500 to consumption, 48,000 to scarlet fever, 25,000 to whooping cough, 80,000 to typhoid and typhus, and 7,000 to rheumatism. The averages vary according to locality, but these are considered accurate as regards the population of the globe as a whole.

Mr. Charles A. Spooner and Mr. Vivian Roberts, both of Bombay, have got through the L.R.C.P. & S. Exam., and L.F.P.S. Glas. qualifications and are now coaching with Dr. Kenneth Campbell in London for the next examination for the Indian Medical Service. We heartily wish them success.

Dr. Lobet draws attention to the great alimentary value of the expressed juice or extract of young and tender maize. It has the advantage over wheat in that it contains a much larger proportion of fats, proteins and salts (which give it decided diuretic properties) are also in good proportion. He proposed to call this preparation "vegetable milk."

The most curiously decorated graves in the world, perhaps, are those of the natives in Zululand, Africa. Some of these mounds are garnished with the medicine bottles used by the departed in their final illness, and the duration of the malady and skill of the physician are indicated in a measure by the number of bottles.

A hedge doctor (a quack) in Ireland was being examined at an inquest on his treatment of a patient who had died. "I gave him inpeacauha," he said. "You might just as well have given him the aurora borealis," said the coroner. "Indate, yer honor, and that's just what I should have given him next, if he hadn't died."

A decree has just been issued in Russia permitting women physicians to enter the Government service. By this fact women in Russia have won an important privilege. The Government service carries with it extremely liberal pensions. It is expected that this will be the forerunner of other extensions and of privilege to women.

A man in the car was telling how good his doctor was "Clever," said he; "well I should say he was. The other day I called him in when I had swallowed five cents. He said if the coin was not counterfeit it would pass and made me cough up two dollars."

The *Progress Medical* cites the case of a Jersey woman who gave birth to a daughter at two o'clock in the evening of 31st December 1897, and to another one about two o'clock in the morning of 1st January 1898, thus making the twins born in different years.

A measure is just being discussed before the German Reichstag, whose purpose is the prevention of the spread of venereal diseases. Any one found guilty of having communicated a venereal disease to another shall be punishable by fine and imprisonment.

Veitch records an interesting case of mal-development of the generative organs in a girl aged 22. The uterus was rudimentary—about the size of a pea—while the vagina was of ordinary depth and fairly capacious. Ovaries and tubes could not be detected. The mammae were absent.

Surgeon-Lieutenant-Colonel O. J. H. Warden, Medical Storekeeper, Bengal Command, receives the acknowledgments of the Government of India for his work in connection with the preparation of plague prophylactic serum in Bombay.

The liver described consisted of 16 lobes separated by deep fissures. It was but little enlarged, the right and left lobes being sub-divided into several smaller lobes. The possibility is suggested of confusing such an organ with growths in the liver, especially if the liver is much enlarged.

A petition has been presented to the House of Lords by the Pharmaceutical Society of Ireland praying that limited companies of unqualified persons should not be permitted to engage in any calling for which personal qualification is necessary.

A woman, 64 years old, swallowed half an ounce of laudanum. Vomiting was induced in 45 minutes by means of mustard-water. After this she was given hypodermically ½ grain strychnin and a solution of potassium permanganate. Recovery was prompt.

Of the seven great physicians of what has been called the "later Victorian Era"—namely, Sir William Jenner, Sir William Gull, Sir Richard Quain, Sir Andrew Clark, Sir Spencer Wells, Sir Oscar Claydon, and Sir James Paget—only two, the first and last named, now survive.

A German doctor, who has been collecting information about the habits of long-lived persons, says that the majority of those who have attained old age indulged in late hours—that is, they retired after midnight and remained in bed late in the morning.

Sunday's returns of the plague show that the coverts were again drawn blank. Really this absence of plague on Sundays is almost attaining the proportions of a phenomenon; in fact, we know of nothing so mysterious as this side of India except the Barisal guns or the reasons of an appointment.

In his report of the 1st July 1905, Mr. R. T. Greer, C.S., the popular Chairman of the Calcutta Municipality, acknowledges that of the cases reported up to the 31st May as cases of real plague, eight of these have been proved to be not cases of plague.

Surgeon-Colonel Warburton and Price and Brigade-Surgeon Lieutenant-Colonel Bourke are appointed Honorary Surgeons to the Viceroy, *vice* Cunningham, Atkins and Edge, vacated.

Archer William Ross Cochrane, B.M., Lond., L.R.C.P. Lond., (Surgeon-Lieutenant, I. M. S. Bengal), and Hormasi Manekji Mainia, L.M. & S. Bombay, Grant Medical College, Bombay, have passed the examination for the F.R.C.S. England.

Authorities differ as to the rate of growth of the human hair, and it is said to be very dissimilar in different individuals. The most usually accepted calculation gives six and a half inches per annum.

A "cute Yankee" has hit upon a novel method of protecting his cashbox from marauding fingers. He sprinkles the box with a powder which has the peculiar effect of dyeing the skin blue, the color being merely intensified by washing.

Abata records six cases in which the secretion of milk was increased by means of massage of the abdominal walls, and he endorses such a procedure, claiming that it is infinitely superior to the administration of galactogogs.

The champion tennis player in Assam is a young European gentleman who has never been out of the country and whose father was at one time an uncovenanted medical officer on the Bengal List.

No parental care ever fails to the lot of a single member of the insect tribe. In general, the eggs of an insect are destined to be hatched long after the parents are dead, so that most insects are born orphans.

The European medical students from India and the Colonies attending Guy's Hospital London, dined together last month at the Holborn Restaurant, and intend to make the event an annual one.

The new French law on accidents to workpeople provides that the drugs and medicines, as well as doctors' fees, shall be paid for by the employer.

Surgeon-Captain Armstrong, Residency Surgeon, Nepal, goes home on three months' leave, and Surgeon-Captain Grant from Mount Abu officiates for him.

Dr. John Barton, F.R.C.S.I., was on Thursday, 9th June, elected Secretary of Council, Royal College of Surgeons, Ireland, in room of Dr. R. H. Woods, F.R.C.S.I., resigned.

Mr. Alfred McCabe-Dallas, B.Sc., of Assam passed the second Conjoint Examination of the College of Physicians and Surgeons, London, from Guy's Hospital.

Professor Haffkine, C.I.E., is not only an eminent chemist and Pasteur Institute bacteriologist, but possesses the degree of Doctor of Science.

The tea estates in Assam up to date have been practically free from cholera. Dysentery, fevers, and simple infectious ophthalmia have however been very prevalent.

Among the next competition for the I.M.S. in August, several are Anglo-Indians, who completed the whole or part of their curriculum in this country.

A neat little brush is attached to the tail of the glowworm, and it is used to keep clean that part of the insect from which the light gleams, so as to make it more distinctly visible.

Only one person in fifteen has perfect eyes, the largest percentage of defectiveness prevailing among fair-haired people.

At the last meeting of the Rangoon Municipal Committee, it was decided to send a Health Officer on deputation to study the plague in India without Government help.

Miss Dorothea Caine, daughter of Mr. W. S. Caine, ex-M.P. has taken the M. D. Degree at London University.

Messrs. Parke, Davis & Co. have established a \$500 fellowship in the University of Michigan at Ann Arbor.

Very many short sighted people have prominent eyes.

FEVER STATISTICS OF CALCUTTA.

Statement of Deaths from Principal Diseases in Calcutta during the week ending 11th June to the 9th July 1903.

Week ending.	Cholera.	Pyrexia.				Small-pox.	Fever.	Bowel complaints.	Also other diseases.	Total.	Total population, according to the census of 1901.	Ratio per 1,000 of population per annum.

Current Medical Literature.

MEDICINE.

Pyrexia a Defensive Mechanism.

A FEW years ago, much was hoped from the antipyretic drugs such as antipyrin, phenacetin, &c., and had it been proved that they really benefited the fever patient, it would have been a strong argument against the present view that pyrexia being like phagocytosis or chemotaxis, in some way harmful to the fever-producing micro-organisms or their toxins, is a defensive mechanism, but the reverse is the case, and while at the Bristol meeting of the British Medical Association, speaker after speaker insisted that it did more harm than good to treat the pyrexia of fever. Dr. W. HALE WHITE points out that those few fevers, that are treated by agents that lower the temperature are, in truth, instances of the exception proving the rule; since ague, syphilitic fever and rheumatic fever, for instance, are treated by quinine, mercury and salicylates respectively. The temperature falls and the patient is better, not because these drugs are antipyretics, but because they are specifics for these diseases respectively and destroying the pyrexial agent remove the cause of the fever. Had the case been otherwise, other antipyretics would be equally efficacious, which they are not. He also thinks the view incorrect that the cold bath does good by lowering the temperature in typhoid fever, since it also diminishes the delirium, the tremor and the prostration, and enormously increases the elimination of toxic products, in any of which ways it would do good by increasing the urotrophic coefficient to five or six times the normal, and as the hypertoxicity diminishes, the general symptoms mend and the temperature falls, so that when the period of pyrexia has fled and convalescence sets in, the elimination of toxins ceases, because the pyrexia has destroyed the organisms and the excretory processes have removed the products of their decomposition.—*The Lancet*.

Cancer a Contagious Disease.

IN his recent *Thèse de Paris*, Dr. LEON NOEL points out that insects seem to have a certain predilection for arboreal cancer, which is a malignant vegetable tumour found in woods and orchards and bears a certain relation to cancer of man. He notes that there is a certain mortality from cancer among persons who dwell in forests, and that it is a well-known fact that country laborers are predisposed to cancer and traumatism, scratches from bushes, &c., bear considerably on the etiology of this disease. Cancer of the lip does not exist at Lyons, and all who go into hospital there to be operated on for malignant growths on the lip, come from the fields, orchards and woods. Insects, he finds, not only carry infective material from tree to tree, but also disseminate it into human food. Large numbers of protozoa live on insects in the form of saprophages which gorged with infective material infest fruit, flowers and cereals, or are washed down into the forest streams, so that any of these could act as the medium of transport for cancer which may thus be propagated by food and by the stream to affect the alimentary tract or any external portion of the body. These conclusions seem hypothetical, but they merit further observation.—*Brit. Med. Jour.*

Diagnosis of Diabetes from Stained Specimens of the Blood.

LUDWIG BREMER describes a simpler method than the one which he originally proposed. A drop of blood is spread over a third or half a slide, and is then exposed to a temperature of about 135° C. for six to ten minutes. As this latter part of the procedure is important, it is discussed in detail. A temperature of 140° should not be exceeded. When the thermometer registers 130° the gas flame should be taken away from the oven. The optimum of temperature lies about 135°, and below 129° the test becomes unreliable. The slides are then placed in suitable dishes containing the stain. A control specimen must always be made. The Congo methylene blue preparation first used by the author is difficult to make and unreliable. Congo red, methylene blue, Biebrich scarlet, and the Ehrlich-Biondi stain all give excellent results. The first three are used in 1 per cent. watery solution. After an exposure of one and a-half to two minutes to Congo red the diabetic blood is either not stained at all or only indifferently so, while the non-diabetic blood is colored red. Methylene blue acts in an analogous way, but Biebrich scarlet stains the diabetic but not the non-diabetic blood, Ehrlich Biondi's stain colors diabetic blood orange and non-diabetic blood intensely violet. Very successful specimens can be made if a contrast stain is used. These specimens may be obtained with a 1 per cent. watery methyl green for one and a-half to two minutes, when both specimens appear green, but especially the diabetic blood. The counter-stain is a 1 per cent. watery eosin applied for eight to ten seconds. The diabetic blood remains green, but the non-diabetic stains red. Many other stains are mentioned, but the results obtained with them are not so good. The specimen may be taken out of the stain, so that the staining can be controlled. Rapid washing and then drying are desirable. Whether the difference in reaction is due to the different alkalinity of the blood must still remain an open question.—*Brit. Med. Jour.*

Rheumatism in Children.

RHEUMATISM being one of the diseases manifesting peculiar clinical characteristics in young children, not observed in adults, emphasis is placed upon the essential variations and necessity of their recognition.

Mistakes in diagnosis of acute rheumatism in the young are frequently due to the absence of symptoms of arthritis, acid hyperidrosis, and pyrexia.

Arthritis is at a minimum; but endocarditis, pericarditis, and chorea are at a maximum; while pleurisy, tonsillitis and vaso-motor and hemorrhagic phenomena are more common, tending to decline after puberty.

The various phases of this affection tend to arise independently of and apart from one another. Endocarditis and pericarditis, often with no warning, are usually rheumatic; if with chorea, fibrous nodules, tonsillitis, pleurisy, erythema or purpura, whether recent or at intervals extending over months or years, they are almost certainly rheumatic in origin.

As the risk of cardiac complications in a rheumatism is in inverse ratio to the age of the patient, the heart should always be examined carefully, even in the absence of all other rheumatic symptoms.—*Archiv. of Pediatr.*

SURGERY.**Extraction of a Bullet from the Brain with the help of the Roentgen Rays.**

Two years after he had been struck in the right temporal region by a revolver bullet that had passed into the cranial cavity and located itself in the brain substance on the left side of his head, a lad, *et. 18*, suffered such intense and almost intolerable headache for which he consulted BRAATZ who examined him with the Roentgen rays, which disclosing the foreign body at the level of the zygomatic arch and a little in front of the external ear the left temporal region was trephined and the dura incised and raised from the surface of the brain but without success, as the operation had to be hurried through, in that the anæsthetic very seriously affected the patient's breathing. The headache vanished but returned so badly, a fortnight after a second attempt had to be made to extract the bullet. After its surface being exposed by opening up the old wound, the brain was explored with a blunt needle which, passing inwards and downwards for about two inches, struck against a hard substance. Dividing the brain tissue along the track of the needle with a blunt knife, BRAATZ used an artery forceps to pull out the foreign body, which was shattered bullet weighing about 41 grains. The patient made a very quick recovery.—*Central Chir.*

Abdominal Section in cases of Prolonged Vomiting.

A WOMAN, *et. 44*, stated that for the past 18 years she had ineffectually tried all manner of treatment to prevent her daily vomiting up all her food at irregular intervals. Dr. NAYLOR, of Hobart, Tasmania, kept her under observation for some months and as he had unsuccessfully tried lavage and several other methods of treatment, he concluded there was pyloric obstruction and recommended pyloroplasty or gastrojejunostomy according to the nature of the obstruction.

Performing laparotomy in the usual manner he found the pylorus deep down and adherent to the liver, but the stomach, which was empty and flaccid, was not at all enlarged, though it was so tied down by several adhesions to the bowel below that it could only be drawn slightly forward. The greater part of the stomach was liberated by separating these adhesions; but the pyloric end was left adherent to the nether surface of the liver. The woman made an excellent recovery and the vomiting trouble ceased. Dr. NAYLOR thinks that the sickness was caused by the adhesions tying the stomach down above and below and producing spasmodic vomiting and tightening or constriction of the pylorus.—*The Lancet.*

Origin of Circumcision.

At a recent meeting of the Anthropological Society of Paris, M. LETOURNEAU said that the ritual of phallo-tomy had its origin and became extended as an act of homage to the deity. Just as the blood or fingers or the hair was offered as a sacrifice by the early Christians, so also was circumcision, which is so inseparably connected with the religion of the Jews and Mahomedans, a symbol of complete sacrifice that is still very widespread, but has become partial by the lessening rigor of morals. The Egyptians circumcised those they vanquished, and the custom still obtains among the Abyssinians. Every warrior who kills an enemy presents his chief with a bloody prepuce, which is returned to him at the close of the 'triumphal ceremony' to be taken home, cured and preserved as trophies as the American Indians do the scalps they wrest from their foes. That this prevailed among the early Hebrews is proved by King SAUL telling the son of JESHA that he would have to bring in the forekins of 100 Philistines before he would accept him as his son-in-law.—*La Nature.*

Recent Experiences with Cataract Operations.

*At the recent Moscow Congress, KNAPP of New York reported 1,080 cataract operations, of which 480 included all complicated cases. The method of operation was usually a simple extraction without iridectomy, and the incision at the border of the transparent cornea almost half its extent. The capsule was opened with the cystotome to the extent of 5 or 6 mm. in the upper part of the iris, so that the torn pupillary edge of the iris and the wounded capsule should not touch. Pressure at the lower part of the cornea easily delivers the lens, but contact of the border of the lid and the corneal wound should be avoided. Both eyes are bandaged afterward and the dressing changed after twenty-four hours, when any prolapse of the iris can be disposed of. Reaction of an inflammatory nature was limited to six cases of slight iritis, two cases of partial wound infection and four cases of purulent infection of the cornea. In 355 operations prolapse of the iris occurred fifteen times (7.6 per cent.) and was successfully treated by iridectomy. Secondary operations were done in 40 per cent. of the cases. In three cases glaucoma following dissection was observed. Recovery was obtained by means of iridectomy, eserine and morphia. In the last 400 cases good vision was obtained in 98 per cent., fair in 4.5 per cent., and total failure in 2.4 per cent.—*Archives of Ophthalmology.*

Coley's Fluid in Inoperable Tumour.

MR. W. H. BATTLE showed a man, aged 30, who had had syphilis six years previously. Four months before admission he noticed a lump under his right arm accompanied by pain, and soon followed by other swellings. Movement of the arm was difficult and it became swollen. Just before admission a lump formed above the right clavicle and another over the right side of the sternum. The swelling above the clavicle was caused by the pushing forwards of the pectoralis major by an elastic tumour of considerable size and irregular shape, which was fixed to the deeper parts but did not involve the pectoralis. In the axilla were numerous enlarged glands of various sizes. Iodide of potassium in increasing doses was given, but did not effect any improvement, so on 5th January portions were removed from the sternal and subclavicular growths, which proved on examination to be fibro-sarcomata containing giant cells. Thereupon he gave half-minim doses of Coley's fluid every other day from 21st January to 21st March, the iodide mixture being continued until 6th March. The dose was then raised to one minim every other day. The man had greatly improved in general health, and now presented only two swellings, one over the site of the sternal tumour and the other under the clavicle, both being comparatively small. He commented on the absence of any reaction, the temperature having been normal throughout.

Cyst of the Pancreas.

THOREN publishes a second case under his care. The first appeared in the Swedish paper *Lira*, 1893, p. 99, and is noted in abstract in HENRICUS's monograph on Cysts of the Pancreas, in *Langenbeck's Archiv*, Vol. liv, 1897, p. 456. The patient was 52. The tumour filled the left hypochondrium; it was fixed to the parietes, and drained. In THOREN's second case the patient was 20. A large tumour filled the left side of the abdomen, not apparently reaching to the left ribs, whilst the pelvis was free. The colon lay in front of the tumour. At the operation a cystic tumour springing from the left side of the pancreas was discovered; it was fixed to the abdominal walls and drained. Several solid masses sprang from its inner wall, and one was partly cut away with a piece of the wall for examination. The wall contained muscular fibre. Traces of the same tissue were also detected in the solid masses, mixed with round cells and numerous giant cells of varied outline.—*Brit. Med. Jour.*

OBSTETRIC AND GYNECOLOGY.**Case of Dead Twin retained to Full Term.**

On 2nd March I was sent for to attend a multipara, thirty-two years of age. On arrival I found that a healthy girl, weighing 7 lbs., had been born about twenty minutes and the placenta had been expelled naturally. The nurse produced a small dead foetus which had come away with the placenta. It measured 8½ in. in length when fully extended and the occipito-frontal diameter of the head measured 1½ in. It had been squeezed quite flat, so that the body was not more than ½ in. thick and the head was still less. It was enclosed in a membrane which could be peeled off it, but the fluids had escaped. There was a small placenta and an umbilical cord 1½ in. in length. The head was rotated backwards and the spine folded down. The mother, whose last child is six years old, is very delicate, suffering from apex systolic murmur and floating kidney. She complained of great pain in the uterus during the pregnancy, and was at times unable to get out of bed for days together.—WALTER C. HEARNER, M.R.C.S. Eng., L.S.A., in *The Lancet*.

Comparative Study of Ether and Chloroform in Parturition.

H. HENSEN announces that the superiority of ether over chloroform for the purposes of parturients resides in the fact that while both suppress the action of the abdominal muscles, the effect of the ether rapidly passes away and the uterus resumes its contractions in five to twenty minutes, while the effect of chloroform is felt for a couple of hours, preventing contractions and thus postponing the expulsion of the fetus and favoring hemorrhage from atony of the uterus. His numerous tests with primiparae and others, covering several years, were made with a bulb in the uterus connected with a barometric tube. He found that the energy of the uterine contractions increases progressively till the rupture of the bag of waters; to subside then until after the expulsion of the fetus, when the pressure increases again to reach its highest point, a remarkable phenomenon which may be due to the increase of thickness in the uterine wall at this moment. He found that five milligrams to two centigrams of morphia have no effect upon the contractions of the uterus and of the abdominal muscles.—*Sen. Med.*

Extra-uterine Pregnancy Lasting Twenty-three Months.

A FULLY developed fetus was exhibited at a recent meeting of the Brussels Anat. Path. Society, which had grown in the tube, in which also the placenta was inserted. After the rupture of the tube the fetus had passed into the abdomen where it had contracted adhesions with the intestines and peritoneum.—*Præse Med.*

Precocious Maturity.

THE process of menstruation was noticed by TOWNSEND in a girl of 19 months' old, weighing 28 lbs. and 30 inches in height. Her breasts were large and the pubic hair 0.25 inch long; but her nipples were not developed. She weighed 9 lbs. at birth, cut her first tooth at 4 months, and at 12 had 7 incisors. Her breasts began to enlarge at the age of 3 months, and blood issued from her vulva at 6 months, since when it had been 'regular' every 5 weeks.

MOORE, *British Medical Journal*, tells of another case who menstruated at 9 months and was "quite regular." At 15 months she was 32½ inches high; weighed 36 lbs; her breasts were very well developed; the nipples large with a dark pink areola, and the cervix and uterus could be plainly made out on digital examination.—*Brit. Med. & Surg. Jour.*

Fertilizing of Pregnancy

Has often proved obstinate to numberless remedies; but POISSON reports good results and permanent improvement without appreciable concomitants, by injecting 0.17 grain

of cocain into the epigastric region once or twice daily immediately before meals. He notes also that the internal administration of cocain is useless.—*Galliard's Med. Jour.*

Bicycle and Gynaecology.

FAUCONER lays down rules for the use and abuse of the bicycle, a full memoir on the subject having appeared in the *Journal des Connaissances Médicales*, 26th August 1897. He maintains that the bicycle is to be recommended in cases where complete normality of the genital tract exists, for the relief of anemia, dyspepsia, neurasthenia, sterility, obesity, deferred appearance of the catamenia in young girls, and in menopause troubles. The bicycle is a therapeutic agent in simple uterine congestion, in amenorrhoea due to imperfect development of the uterus and ovaries, or to other causes involving simple debility, including nerve shock; in nervous and congestive dysmenorrhoea; in simple deviations of the period, such as a supplementary show between the normal catamenia; and in cases of fibroid when all hemorrhage has ceased. The bicycle is allowable in mechanical and membranous dysmenorrhoea; in displacements and flexions; in mild and painless cases of chronic metritis after labor and abortion; and in the leucorrhoea of ammenia. Lastly, the bicycle must be absolutely forbidden in amenorrhoea associated with phthisis, cancer, diabetes, organic disease of the heart, and albuminuria and organic renal diseases; in metrorrhagia or excessive menstruation; in acute metritis, perimetritis, salpingitis, ovaritis, pelvic abscess, and parametritis; in hematocoele and bleeding fibroids; and, lastly, in vulvitis and vaginitis not thoroughly healed.—*Brit. Med. Jour.*

Perforation of the Uterus during Sounding or Curettage.

JAKREISS and GLASER, in papers on the above subjects, record three interesting cases of this accident. The former while curetting the uterus in two instances, felt the instrument suddenly disappear upwards, but was unable to satisfy himself that the curette had entered a dilated Fallopian tube. Although in one case there was sharp hemorrhage following the accident, both patients made good recoveries. In another case he was conscious of perforating a senile atrophied organ with the sound, and subsequent symptoms—slight elevation of temperature, localized peritonitis, and meteorismus—served to confirm his fears. Caesotomy was performed on the fourth day, but no wound of the peritoneum could be discovered, the site of the perforation presenting only an inflammatory redness and thickening.

GLASER'S case was one of metrorrhagia continuing for three months after child-birth. In order to determine the direction of the uterine canal, the cervix was steadied by a tenaculum and a sound introduced. Without the least pressure having been made, the instrument glided upward as far as the handle. Fearing untoward results, total vaginal hysterectomy was at once performed. At the apex of the removed uterus, near the left tubal insertion, four contiguous perforations were to be seen, two of which were united by a laceration. The surrounding tissue was "mushy," and comparable to "goosefat" in consistency.

[NOTE.—These cases, as also the several similar ones recently reported, teach the exceeding care with which all manipulations with sound or curette should be conducted. In most instances of uterine perforation more force has been exerted in using the instrument than the operator is conscious of. While considered one of the simplest of gynecological operations, uterine curettage should not be lightly undertaken, especially by one unaccustomed to the use of instruments.]—*Med. Age.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Changes of Blood Coagulation in Living Nerves.

"In regard to the Morphology of Extra-vascular Coagula Non" is the title of an article written by Professor ARNOLD, of Heidelberg, in the *Archiv. für Pathologische Anatomie und Physiologie und für Innere Medizin*, Band 150, Heft 8.

ARNOLD describes the different microscopical changes which take place in extravasated blood inside of the animal body. One colored plate is added to the paper, showing the changes that take place in the blood-corpuscles and fibrin. ARNOLD thinks that the main cause of coagulation is not by the white cells, as is generally believed, but by the red corpuscles. Coagulation is a very rapid process, and in its early stages no changes can be seen in the white cells. The erythrocytes, however, discharge a visible substance and are broken up as rapidly as the fluid becomes solid. If one or both have the power to transform the fluid, most probably it will be the one which adds a substance to the coagulating material. ARNOLD does not deny the great activity of the white cells, and admits that perhaps a coagulating ferment may be discharged by them. As the changes in the leucocytes become apparent only after coagulation has begun there are no visible proofs for their causative influence.—*Med. Jour.*

The Constituent of the Suprarenal Capsule which Raises Blood Pressure.

In the *Johns Hopkins Hosp. Bull.*, BALTIMORE, ABEL and CRAWFORD contribute an article on this subject. SCHAFER and OLIVER and other physiologists have shown that a very small quantity of an aqueous extract of the medullary substance of the suprarenal gland raises the blood pressure to a great height above the normal. It also revives a heart which has been severely poisoned with, for instance, chloral hydrate. BATES (*New York Med. Jour.*) found that its application to the eye caused marked constriction of blood vessels and pallor. He uses it in prolonged operations to prevent hemorrhage and to indefinitely prolong cocaine anesthesia. These watery extracts are mixtures of several unknown substances. After reviewing previous attempts to obtain the pure active substance which the authors think may prove to be of great therapeutical value, they describe their method of obtaining it as a benzoyl compound. Split off from the benzoyl, it appears to be an alkaloid closely allied to the pyridine bases or to the pyrrol compounds (these bodies are known to raise the blood pressure very markedly). It is therefore most probably an alkaloid of comparatively simple chemical constitution. Its sulphate is crystalline, and is physiologically very active. Pyro-catechin cannot be split off from it, and as they were unable to positively detect pyro-catechin in the gland, they consider MUELMANN's statement as to its being the constituent which influences blood pressure as incorrect. Tracings of its effect on blood pressure are given.—*Med. Jour.*

Locomotor Ataxia.

PHILIPPE has contributed a well-illustrated study, from anatomical-clinical stand-point, of the medullary localisations in this disease. He first considers the topography of the lesions, after a new architecture of the posterior columns. He rejects all the methods of determination, except that of secondary degeneration. His arrangement can be easily followed by a reference to his figures. He then discusses the histological nature of the tabetic processes, classifying them as interstitial and parenchymatous. The former he regards as entirely secondary to the latter, which is the primitive change. It affects the posterior roots and posterior columns, but leaves the intervertebral ganglia intact. The change affects the myelin sheath, bringing about a segmentation-like

granular degeneration, resulting in a "beaded" condition of the nerves. The nuclei of the nerves are not multiplied, but the number of nuclei of the axis cylinder was not determined. The pathology of the disease has two types, the benign and the grave. In the latter the lesion is in the cord, resulting in very rapid destruction of the posterior columns, both ascending and descending. In the former, on the other hand, the lesion is in the posterior roots, outside the cord, and has little tendency to spread. It is these that especially exhibit pain, white numbness and tingling indicate rather an affection of the cord. Motor inco-ordination does not necessarily follow a lesion of the "bandelettes externes".—*Edin. Med. Jour.*

Ichthyosis and Arterial Atrophy.

MM. GASTOU and EMBRY furnish an interesting contribution to the pathology of ichthyosis in the *Journal de Clinique et de Thérapeutique Infantile* of 24th March 1898. The disease, as observed by them, occurred in two children aged respectively twelve and ten years, and was of the granular variety, each hair being the centre of a minute horny plate. Their father was troubled with the same condition of skin and he, two years before the birth of the elder child, had syphilis. The most interesting feature about these cases, however, is that they exhibited a conjunction of ichthyosis with marked arterial attenuation as expressed in a hardly perceptible thready pulse in both radial arteries with cyanosis of the extremities. This peculiarity has also been noted in ichthyosis by M. VARIOT. MM. GASTOU and EMBRY regard both the skin disease and the arterial shrinking as evidences of a common dystrophic change—possibly in these cases related to the parental syphilis but not necessarily dependent on this cause as a rule. They note another case in which the same condition of skin and blood-vessels was observed by them and in which the underlying hereditary taint was that of tubercle, and they believe that alcoholism and other hereditary disorders exercise the same influence.—*The Lancet*

Staining of the Amœba Coli.

THE amœba coli is difficult to recognise, except in the discharges, and then only when in a living condition, and it does not stain by the ordinary basic nuclear stains, such as methylene blue. MALLORY (*Jour. of Exp. Med.*, 11, 1897, p. 529) suggests the following methods, which he states give a differential stain, rendering the recognition of the parasite certain:—

I. For sections (liver, intestine, hardened dysenteric discharges, etc.)

- (a) Fix tissues in alcohol
 - (b) Stain sections (paraffin) in a saturated aqueous solution of thionin for 5-20 minutes
 - (c) Wash in water
 - (d) Differentiate in a 2 per cent. aqueous solution of oxalic acid for $\frac{1}{2}$ to 1 minute
 - (e) Wash in water
 - (f) Dehydrate in 95 per cent. alcohol.
 - (g) Clear in oil of bergamot
 - (h) Wash with Xylol and mount in Xylol balsam.
- The nuclei of the amœbæ are stained brownish red, other nuclei blue. Conversely preparations proved a failure.

II. Unna's differential stain.

- (a) Harden in alcohol
- (b) Stain sections in Unna's polychrome methylene blue solution (Gräbler's) $\frac{1}{2}$ hour all night.
- (c) Decolorise and differentiate in a small dish of water, to which are added a few drops of Gräbler's glycerol-alcohol mixture.

- (d) Wash well in water.
 - (e) Alcohol, oil of bergamot and mount as in I.
- Both may give better results with the discharges.—*Thomson*

THE JOURNAL OF MEDICAL SCIENCE AND THE PUBLIC HEALTH SERVICE

What ails the medical profession, especially of those members of our profession who are engaged in the public health service, to the extent of being so by Dr. Smith, the indefatigable secretary of the Jenner Society. It is quite true, as he says, that in the vaccination controversy most of the talking is done by one side—that which deems JENNER to be a charlatan and vaccination a "filthy rite." Their letters and pamphlets, which constantly go over the same ground, teem with unverified assertions and are often disfigured by unwarranted abuse of the medical profession. Occasionally here and there a medical man ventures to give utterance to what he believes to be the truth based on his personal experience and on the accumulated facts of a century of vaccination. He often suffers for his well-meant temerity; for we know of hardly any subject in which personal vilification has more frequently sufficed to take the place of argument. It is too much to expect that any professional man should subject himself to such attacks at the hands of persons whose real outruns discretion and even decency of debate. Nor can we expect the Jenner Society to successfully deal with the multitudinous onslaughts that are now being made upon the practice it was founded to promote. Therefore it would be well for those who have the care of the public health—who are well informed upon the question as to the utility of vaccination and who could readily meet the arguments advanced against it—to descend into the arena. On the other hand, it would not surprise us to learn that strong as is the opinion held by the vast majority of the profession upon the benefits which vaccination has conferred upon mankind, there may well be a feeling of indifference to active propaganda of their views. Even the love of humanity may be chilled by the violent language with which the actions prompted by it are received; and so far as compulsion in the enforcement of a medical prescription is concerned, there are few medical men who would support it were it not that they know its value. Nor does the question of "compulsion" or "no compulsion" necessarily enter into the sphere of the medical man's action. That is a political measure—a procedure adopted by the State deliberately with the intent of safeguarding the people so far as is possible from a disease which was once so common but which, owing to vaccination, has declined in intensity and extent.—*The Lancet*.

Syphilis and Prostitution.

WERNER, in the *Monatsschrift für prakt. Dermatologie*, Vol. xxiv, Nos. 4, 5, refers to the subject of syphilis in the children of prostitutes. His observations were made in the general hospital of Hamburg, where account was taken of all the children born of prostitutes. Of 185 mothers, 58 had never had syphilis, but the remaining 127 were suffering or had suffered from the disease in its various stages. Those mothers had 243 children, of whom 35 per cent. passed from observation. Of the remaining 218, 186, or 85 per cent. died within the first twelve months. Of 51 children of uninfected mothers, 29 died, or 57 per cent. Of 167 children whose mothers were syphilitic 106, or 73.5 per cent. died. Of these 167 children, 90 remained free from congenital syphilis, 77 were diseased; of the former, 46, or 61 per cent. died; of the latter, 66 or 78 per cent. died.

The investigation thus revealed a very high death-rate among the children of prostitutes, even when they were not the subject of syphilis.—*Phil. Med. Jour.*

Age of Parents and Its Influence on Their Progeny.

JANSEN has brought an interesting subject under the notice of the *Division of the Hungarian Statistical Bureau*,

wherein he reports from his carefully investigated data that the offspring of a parent between twenty and twenty-five are likely to be weak and feeble, but between twenty-five and forty-five years strong. The mother has most robust children between twenty-five and thirty-five. More healthy children are born when the mother is about ten years younger than the father—10 per cent. more favorable than when about same age.—*Gaillard's Med. Jour.*

Milk Contamination.

In the *Journal of Comparative Medicine and Veterinary Archives* for April, Dr. M. P. RAVENHILL points out that the chief sources of contamination are (1) the animal; (2) the hands of the milker; (3) the dust of the stable. In regard to the first, he recommends keeping the udder of the cow, the inner side of the legs, and the teats clipped, and well brushing and wiping of the parts with a wet sponge before milking, as the moisture serves to hold in place those germs that have escaped the brushing. Careful washing of the hands and a frequently laundered blouse or flannel duster are recommended for the milker; a separate milking room, where possible, and under other circumstances cleanliness of the stable and the avoidance of stirring up dust before milking from the third precaution. The "fore milk" (first milkings) should be discarded, and the practice of lubricating the teats and the milker's hands therewith is especially condemned; vaseline, if requisite, should be used in place of it, as this helps to fix the germs. Care to exclude dust and maintenance of a low temperature are the principal precautions to be observed subsequently, while the vessels into which the milk is drawn should be steamed or boiled. Glass vessels are especially commended. Pasteurization—i.e., a partial sterilization, the degree of heat employed being sufficient to kill all except spore-bearing (e.g., anthrax, tetanus, etc.) germs—is insisted on; this is effected by heating the milk to 135°F. and keeping it at that temperature for twenty minutes.—*N. Y. Med. Rec.*

Physician not held to Standard of Infallibility.

THE law does not require of a physician or surgeon absolute accuracy, either in his practice or his judgment. The law does not hold physicians and surgeons to the standard of infallibility, nor does it require of them the utmost degree of care or skill of which the human mind is capable, but that, while in the practice of their vocation, they shall exercise that degree of knowledge and skill ordinarily possessed by members of their profession. This is the declaration made by the supreme court of Nebraska, in the case of *VAN SIKES vs. POTTER*, December 1897, which was an action brought to recover damages from Mrs. POTTER and BETHOLDS for alleged negligent treatment of a knee cap fractured in a baseball game. The trial resulted in a verdict and judgment in favor of the doctors, which the supreme court affirmed. The evidence, the supreme court holds, sustained the finding of the jury that the defendants did not contract with the plaintiff to effect for him a permanent cure, and did not contract to visit and treat him until he was cured. As to whether they had pursued the proper method in setting his knee cap, by wiring the fractured portions together, the supreme court says, "as is usual, the experts for the plaintiff agreed with his contention, and the experts on behalf of the defendants agreed with their contention," and it decides that they were not guilty of negligence in the treatment given the plaintiff, including the leaving the point of a drill in the bone when broken off in drilling a hole in one of the pieces of the knee-cap, owing to a movement of the plaintiff's leg. Upon the issue, made by the pleadings, as to whether the defendants agreed to visit and treat the plaintiff until he recovered, the court holds that they were properly permitted to testify that at the date of their last visit to him, they informed him that they should not return unless they should be requested so to do. It also holds that in such a case, testimony on surgery, though standard authority on the subject, could not be read to the jury as independent evidence of the opinions and theories therein expressed or advocated.—*Jour. Amer. Med. Assoc.*

THERAPEUTICS AND PHARMACOLOGY.***Biniolide of Mercury as a Substitute for Potassium Iodide.***

HODDAY says the great objection to the use of potassium iodide in veterinary practice, especially for the larger animals, where full and repeated doses have to be employed, is its expense. About two years ago, in the course of conversation, Professor EDGAR, of Dartford, observed that he had been using the biniolide of mercury as a substitute for potassium iodide in the treatment of actinomycosis, and that he found the treatment to be attended with an equal amount of success.

The recipe used consisted of from 2 to 6 grs. of biniolide of mercury dissolved in an ounce of water by the aid of from 5 to 10 grs. or 12 grs. of potassium iodide. HODDAY has been able to collect a fair number of instances in which it has been tried successfully on cattle suffering from actinomycosis. In the treatment of chronic elephantiasis and of tumors of the shoulder and elbow, the biniolide has been used in the clinic at the Veterinary College as a substitute for potassium iodide, and an equal amount of success has been obtained, together with the advantage of obviating the alterative effect of the mercury. Professor EDGAR has also tried it successfully in the horse for the dispersal of glandular enlargements, for capped elbows, and for scirrhus cords; he has also found it a valuable agent as an astringent to the lactal secretion in mares and cows.

Summing up the results, HODDAY concludes (1) That the agent is very much cheaper to use than potassium iodide. (2) That the results which he has been able to collect regard, and its value in actinomycosis confirm those which Professor EDGAR had already obtained. (3) That the observations which Professor EDGAR and himself had been independently making at the same time upon its therapeutic effects as a resolvent, specific and alterative in certain diseases of the horse, appear to demonstrate its value, and to agree in almost every detail. (4) They have each found that, as is frequently the case with potassium iodide, failure to continue with the medicine for a sufficiently long time may cause a relapse, the tumors again enlarging.—*Gaillard's Med. Jour.*

Best Means of Administering Salicylates.

It would be a work of supererogation to undertake to prove the great and permanent value of the salicylates in the treatment of rheumatism in its various forms. For over twenty-five years, salicylic acid and its salts have been recognized as standing at the very head of remedies in this class of diseases. There are, however, many grave drawbacks to the use of either the acid or any of its salts, alone in a treatment which may last, as in rheumatism, gout, and neuralgia, for a long period of time. Being a powerful antiferment, and sharing this property with most of its salts salicylic acid impairs digestion, and soon sets up a dyspeptic condition almost as intolerable as the pains which it is intended to overcome. Its after-taste can be covered and concealed in no manner yet discovered, so that very soon the patient takes it only with great difficulty. In toulaine, however, the salicylates are so combined with coagulants that there is little or no reactionary rebellion against them by the organs of digestion and assimilation, while their efficacy is not affected in the least. The experience of thousands of physicians corroborates this statement, and concurs in the fact that toulaine affords the very best method of administering the salicylates.—*Virginia Med. Semi. Monthly.*

Dika Fat,

WAXON is extensively used by the natives of the Cameroons for culinary purposes, is a vegetable fat obtained from the wild mango. The fruit is dried and afterwards boiled, when the fat, which separates, is skinned off and dried.

It is a little darker colored than palm oil, but has a most agreeable flavor, and is not only readily digested but also renders whatever is cooked in it extremely palatable. Dika, or Odika fat as the natives call it, is certainly preferable to lard and infinitely more nutritious than margarine; but until regular mangoes farms are established, this fat cannot be procured on anything like a profitable commercial basis.—*Chem. Trade Jour.*

CORRESPONDENCE.

THE ANGLO-INDIAN CAUSE.

To the Editor, "INDIAN NATIONAL RECORD."

Sir,—The following letter appears in the *Pioneer* of the 7th July, and will be read with interest by the Anglo-Indian *Alumnae* of the Record:—

"EURASIAN, ANGLO-INDIAN, OR BRITISHER.

To the Editor of the *Pioneer*.

"Sir,—The transient victory of the official clique which ruled the roost at the recent meeting of the Anglo-Indian Association held at Allahabad with the object of eliminating the term 'Eurasian' from the designation of that association, has been characterised as a triumph of 'common sense over touchiness,' and the *Pioneer*, referring to the over-riding sentiment of that meeting, says: 'the Eurasian would not be less a Eurasian when lumped indiscriminately with the Anglo-Indian.' Officials, and other imported Britishers whose vested interests are identical with officialism in India, urge that the objections to the application of the term 'Eurasian' to persons of mixed British, European and Indian descent, are purely sentimental. Even if they were so, they should command respect and sympathy from all true-hearted Englishmen. But the objections are chiefly of a socio-political nature, and no party is more thoroughly cognisant of this important phase of the present agitation than that section of the non-domiciled European community which obtains its foothold in India by sheer merit of patronage from the Secretary of State for India, and retains this unjust reservation of the higher or 'imperial' posts in the Indian services by a usurpation that is as cruel in its arbitrariness as it is unlawful in its violation of a distinct Act of Parliament (Statute 33, Victoria, Chapter III, Section 6). Leaving aside, however, for the moment, the political rights and privileges of the domiciled British community (in which are included all Europeans permanently domiciled in India and their descendants of mixed or unmixed descent) and reverting to the main object of this epistle, let us ask (1) what does the term *Eurasian* signify? (2) what does the term *Anglo-Indian* signify? and (3) what is the law with regard to the claims of *nationality*? I will endeavor to answer these questions briefly.

"(1). The term Eurasian is etymologically and anthropologically a misnomer. It was intended to signify an admixture of race between European and Asian, but in order to be grammatically and ethnologically correct in significance, the word ought to be *Europe-Asian*. As it stands, the Greek prefix *Eur* or *Eros* means broad, therefore the word "Eurasian" signifies broad Asian, which is absurd. To attempt to bolster up the etymological basis of the term on the plea of euphony, is simply ridiculous. The credit or discredit of coining this hybrid term has been given to Mr. METCALFE, an old Bengal Civilian, while others ascribe the 'honor' to the Marquis of Hastings. That the designation was looked upon with intense disfavor at the earliest period of its inception, is proved by the fact that at the time of the Anglo-Indian delegation of Mr. Richards to the British Parliament in 1880, to plead the cause of the domiciled European community before that august tribunal, an indignant protest

was made against the use of the word "Eurasian" towards those of that community who were of mixed British and Indian descent. It was then held to be a term of reproach, and as such it has never lost its racial disapprobation. As a class-name it serves to perpetuate 'caste' distinctions in a community that can ill afford to raise artificial barriers in its already much divided camp.

"(2). The term 'Anglo-Indian' is etymologically and ethnologically the true and correct designation that should be applied to persons of mixed British and Indian descent. Under no circumstances (save that of 'domicile') can a person of pure British descent, whether born in Great Britain or in India, be termed an 'Anglo-Indian,' if we have strict regard to the etymological and anthropological or racial significance of the term. But as Britishers domiciled in India have a right to be embraced or classified under a designation which indicates their domicile, they may fitly be termed 'Anglo-Indians,' and they have very rightly so adopted this nomenclature for themselves. Hence we have in the term 'Anglo-Indian' a designation which aptly embodies all Britishers domiciled in India and their descendants, and so we claim that their representative associations should bear this and no other name. And this brings me to consider the veiled sarcasm of the passage I have quoted from the *Pioneer*, namely, the disputed claim of the so-called Eurasian to be 'lumped indiscriminately with the Anglo-Indian.' Now what does the lumping discriminately or indiscriminately of the Eurasian with the Anglo-Indian really mean? Has he any right to be so 'lumped' or classified? Now I claim that there is no such individual as the *Eurasian*, since no one of any conceivable race can be forced or conjured into fitting into a designation that does not correctly, and therefore lawfully, describe his race or nationality, or domicile. There are such persons as *Europe-Asians* such as Anglo-Indians proper, Franco-Indians, Germano-Chinese, Hispano-Burmese, Russo-Siberians and so forth, but with all due deference to METCALFE and HASTINGS, there is no such person as a *Eurasian*. Again, an Anglo-Indian or a so-called British Eurasian, has a national claim to be 'lumped' not alone with his own class, the Anglo-Indian, but his claim must be carried further, to its legitimate goal. He must be 'lumped' with his kinsmen, the Britisher, and with no one else, for (3). What is the law with regard to the claims of nationality? It is this, that a man claims his nationality from his father, grandfather or great grandfather. Hence the sons, grandsons and great-grandsons of English, Scotch or Irish fathers from Indian mothers, grandmothers or great-grandmothers are English, Scotch or Irish, just as their fathers, grandfathers or great-grandfathers were, and therefore the so-called Eurasian has a lawful right and an unquestionable claim to be 'lumped' not alone with Anglo-Indians but with the proud-cooled Britisher. He can have no outcast position. He can suffer no shadow of ostracism in the eyes of British law as to his nationality. His inclusion in the heritage of the Britisher is as inalienable and indisputable as that of the proudest of pure-blooded Englishmen. It is upon this strong and sure foundation of their national birthright that all domiciled Britishers and their kinsfolk in India must claim their socio-political rights

and privileges before the great tribunal of the United Kingdom, the Parliament of Great Britain and Ireland. All the old-fashioned shackles of caste-names and hybrid classifications must be torn away, every distinction that raises an artificial barrier to the cohesion and solidarity of the members of the domiciled British community of India must be eradicated, and a union, indissoluble by such unworthy characteristics as prejudice, false pride, jealousy and other hindrances, must bind together these rapidly growing and important members of the British race in India in defence of their common interests, till the prophecy of Lord DUFFERIN in his famous Minute on the 'Anglo-Indian Regiment Question' is realized in all its potentiality, namely, 'that the Anglo-Indian race once united can never be repressed.'

Yours &c., JAMES R. WALLACE, M.D., F.R.C.S.
50, PARK STREET, CALCUTTA, 4th July 1898.

TREATMENT OF PLAGUE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It has given us no small uneasiness and vexation of spirit to know from the ordinary sources of information that the dire disease styled the bubonic plague is carrying off hundreds of people in the metropolis of Western India. The plague has already numbered some 7,500 persons as its victims. We in this part of India deeply sympathize with our fellow countrymen in Bombay who are put to a great deal of inconvenience and stand in jeopardy of their lives owing to the severe visitation of the plague. Experts from Europe have, from the very outset, been trying to grapple successfully with the disease, and have proposed various remedies. But it is indeed a misfortune that no treatment of a satisfactory nature has yet been found out. The disease is only of a very late introduction, and it appears to be one of the most dangerous and terrible disease that can afflict humanity.

The attention of distinguished medical men and sanitary scientists has hitherto been mainly devoted to the protective inoculation in order to scare away the plague, and so far their attempts in this direction are not reported to be an unqualified success. With all due deference to the noble array of distinguished medical men working in the field of plague research, I beg to submit that much good may be expected if the Altera-Unio system of treatment be adopted under which proper medicines should be administered which have a marked tendency to destroy the microbe and then the morbid humours and accumulations must be washed off by good purgatives followed by aromatic tonics for improving the strength of the patient. In this way the germs will be destroyed, the further progress of the disease arrested, and the blood rendered less favorable to the action of the diplo-bacteria. For this purpose I would suggest the administration of creosote in minute doses in the first instance by which short work will be made of the germs, or they will be deprived of their destructive power. Creosote has been found to be an efficacious remedy in diseases of the digestive and respiratory organs, and it possesses the peculiar and important property of acting as a powerful disinfectant, parasiticide and cleansing agent of the animal economy. While the germs are thus rendered powerless, the bowels should be acted upon freely by purgatives and nothing would suit

the purpose better than *salinis* powder. *Salinis* powders empty the bowels of the morbid and irritating matters and thus prevent the formation of the painful tumour in the glands of the groin and other parts. After these preliminary processes are gone through, the system should be invigorated by tonics. In this connection I beg to point out that the internal use of calcium sulphide is also calculated to destroy the micro-organisms, and it is generally believed to be an efficient remedy for boils and other eruptions of the body. Thus the double therapeutic effect of this medicine may be tried in plague-stricken individuals. I think it may also be of use to lay before the public the fact that the bark of the neem tree is a remedy of the greatest value in the treatment of febrile conditions accompanied with great nervous prostration and eruptions on the body. The bark may be given in conjunction with a little pepper powder in the form of a decoction and a few drops of essence of camphor should be added to it. The bark of the neem tree has not, I think, been sufficiently recognized in European practice, and I would refer your readers to an interesting article in the Manual of the Madras Administration, Vol III, page 576, for detailed information regarding the medicinal virtues of the bark and other valuable substances obtained from the neem tree. It is also supposed that Dr. DYMOCK should have included the neem in his "Vegetable Materia Medica of Western India." The neem bark acts as a powerful absorbent of putrid materials from the body, while the pepper serves as an antidote to certain poisons in the system and the camphor helps to keep up the temperature and energy of the internal organs, and owing to the combined action of these remedies, the impurities which have been allowed to accumulate inside may be eliminated from the system. I have merely shown what benefit can be derived from the use of the medicines described above. It is not my purpose to criticise the measures of relief proposed and carried out by experts in the profession. It is only my deep love for humanitarian and life-saving work that has prompted me to address the public in this way and to express my opinions freely on the subject, and I humbly crave the indulgence of the public if I have over stepped the bounds of propriety by writing this letter for their information.

Yours &c., J. PETER PILLAI, C.M.S.

THE MORAL ASPECTS OF MALTHUSIANISM.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I regret my inability to fall in with the views expressed in your issue of the 16th June as to the immorality of the "artificial prevention of conception" which, I think, is perfectly justifiable and even imperative under the following conditions.—

(a) When the shock of parturition and the double strain of gestation would necessarily endanger the life of a woman who has some pelvic deformity or disease, or is suffering from a low state of health.

(b) When either the husband or the wife (or both perhaps) is infected with syphilis, phthisis or other disease capable of hereditary transmission.

(c) Where the married couple are not in a financial position to support a family of children.

Most of the objections raised against prevention of conception are ably met by Mrs. ANNE BESANT'S "Law of Population" and Mr. J. S. MILL'S "Essay on Nature" and the suggestion that neo-malthusianism is unnatural or immoral is just as irrational as to insist that man should follow Nature and make the spontaneous cause of things the model of his voluntary actions when it is a well-known fact that were they left to their own sweet will instead of being controlled by art, many natural forces would simply run riot and frequently lead to destruction of property, intense sufferings and loss of life.

Continence is a very good thing in its way, and should certainly be encouraged in the unmarried especially; but it has its chapter of woes also in the shape of spermatocele, spermatorrhoea, prostatitis, ovaritis, leucorrhoea, menstrual disorders, &c.

If killing the spermatozoa or the voluntary emission of semen for purposes other than conception be immoral, then (1) every act of sexual congress is immoral, because numberless spermatozoa are discharged and killed for the sake of the four or five needed to fecundate the ovum; (2) every barren wife is immoral, and (3) so also every marital couple where co-ordination between the germ cell and the sperm cell does not take place.

A very unkind and unjust opinion is formed of 'woman' and a direct insult hurled at every one of our wives, mothers, sisters and daughters by the despicable insinuation. "The more general knowledge of the checks to conception would foster immorality in the unmarried by giving them facilities to gratify themselves without any corresponding burdens, while to the married it would open the door of infidelity and thus create a perpetual cause of jealousy and suspicion with the inevitable effect of wrecking the peace and happiness of home." What a detestable estimation of gentle woman. To say that "fear of conception" only keeps women chaste is to deliberately ignore the innate chastity of women and to judge the rule by its exceptions, as well as forget that man is just as much, yes, and very often a good deal more, to blame for woman's lapse from virtue. He who continually broods trouble breeds it. I quite admit that there are a few women who would be only too willing to avail themselves, at every opportunity, "of artificial checks to conception," but the adoption of such checks is not always due to lasciviousness, for there are women and women there be (and men also) to my knowledge whom it would be utterly impossible to tempt to stray from the path of virtue and yet safety to themselves and their duty to their existing progeny has impelled them to artificial means (such as douches, pessaries, wads and *budrachas*) for the prevention of conception.

There is barely anything in this world, whether knowledge, pleasure, vice, power or duty that is not open to the risk of being abused, but it is irrational to let the likelihood of its being abused preponderate the intrinsic worth of anything. Thus fire, which is indispensable for domestic purposes, such as warmth and preparing our food, and for civilization and the production of 99.5 per cent of our necessary manufactures becomes a terrible evil in the hands of an incendiary, and no sensible man contends that

knives or razors should not be made because a few lunatics have cut their throats with them.

The population question has always been and will continue to be an exceedingly vexed one, but I hold and so does every wise man with me that as it is cruelty and madness to force into the world numerous progeny whom we can neither feed nor rear properly, there is not an iota of immorality in the desire to restrict one's family even if that restriction has to be obtained by the artificial prevention of conception.

Yours &c., HARA KALI SEN, C.R.M.

RAIGUNJ.

THE C. D. ACTS IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I should like to ask "A Medical Man" to give us the reasons why the old C. D. Act did not perform all that was expected of it, and tell us what were the faults in its construction and working.

This question of venereal disease is one in which I am interested. I don't profess to know much about it physiologically, and like "A Medical Man" I don't go by statistics, though I should earnestly beg of him when he does use them, not to make such awful blunders, as to assert that 8,000 cases of venereal disease are sent home annually when he means 800. My interest in the question is purely from a moral stand-point, and in that connection I should like to reply to "A Medical Man" against his interrogation. Is it preferable to leave the women to rot?

That surely is not the point involved in the C. D. Acts. It is the motives behind the C. D. Acts that their opponents object to. If a victim of the disease seeks medical treatment in the ordinary way, Dr. HUNTLY would be the last man to refuse assistance; as he would be the first, I am sure, to encourage philanthropic effort in the part of hospital authorities if all ulterior motives were removed. Why will the "C. D. Acts" advocates so persistently avoid the real crux of the matter and wax indignant, with their "Will you leave the women to rot?" If there be only two alternatives (1) "Safe vice" (supposing such possible) and (2) "Disease," then I should say disease is better, because disease will press home the fact that every man must reap where he has sown.

"A Medical Man," however, is aware that there are other alternatives, known to those who believe that man is a moral being and able to live after a moral fashion.

I am glad "A Medical Man" does not object to the women of England being informed in the question. The sooner fathers and mothers make the question of a man's personal purity the first consideration in any proposals of marriage they receive for their daughters the better.

I have heard that a soldier wrote out from England to a friend in this country, that the father of the girl he was courting asked if he had "venereal." Let such conduct on the part of fathers be more general, and perhaps the soldier will exercise more restraint when in this country, where so many seem to think that all restraint may be thrown to the winds.

The object of my letter, however, is to ask "A Medical Man" to explain clearly the faults of construction and working which prevented the old Act from doing all that was expected of it.

* May be obtained from Messrs. Barker Brothers, 160, Chancery Street, Calcutta.

One should like to know, exactly, what is always occurring to prevent the advent of the millennium in "Edmond Vies." I fear the date of its arrival coincides with the Greek Islands.

Yours &c., A NON-MEDICAL READER.

FAIR PLAY FOR THE I. S. M. D. TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In course of conversation a few nights ago with a friend, over the miserable feeling existing about the various causes for the grievances in the unfortunate Military Assistant Surgeon class, the hard case of Assistant Surgeon J. P. MONTGOMERY was discussed, and on reference we found that this young man was tried and sentenced to reduction in July 1896, fully two years ago. His supposed crime and his sentence with its legality we'll leave for discussion elsewhere, as I should like to see it pilloried by Mr. LABOUCHERE in *Truth* with Surgeon-Major DENNY's case. The *Record* had its say at the time and did good service in exposing and publishing the private note written to the members of the court martial by a vindictive A. M. S. Officer, but my chief reason in writing to you now is to ask if para. 378 B. of A. R. I., Vol VI. (Medical) has been expunged or rendered void? We are told that a Warrant Officer "reduced by sentence of court martial to a lower class" (and MONTGOMERY was virtually 'reduced,' as, at the time, his promotion to the higher class was a certainty) "will be eligible for promotion to his former class on the recommendation of the Surgeon-General with the Government, after not less than one year from the date of the sentence of the court martial," &c.

Who is responsible for the omission? Are the SUBORDINATE GRADES of this service left to the mercies of Baboos in the Surgeon-General's Office, as they are in the offices of P. M. O's. of districts? MONTGOMERY has been in active service lately, and perhaps his several medical officers can report whether his services in the field are worthy of recognition. If I am not mistaken, the poor unfortunate man has appealed twice, asking consideration from the Commander-in-Chief, but his appeals were returned "as the case could not be re-opened," but neither of them reached the Commander-in-Chief as far as I am aware.

It is painful and disgraceful to see the state of feeling existing in the Warrant grades of the service, they are more than dissatisfied, and with good reason too.

Yours &c., FAIR PLAY.

SOME MEDICAL APPOINTMENTS FOR MILITARY ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With reference to the letter from "One Interested" in your issue of the 1st July under the above heading, I fail to see the justice of his argument in stating that the appointment of chief medical officer to the Eastern Bengal State Railway might be profitably and innocently filled by a commissioned officer of the Military Assistant Surgeon class, or a first class Military Assistant Surgeon over five years.

The question of seniority in filling the majority of appointments is left out of consideration in the present day, as also professional attainments, as is generally seen. Why then should this post be solely and specially the preserve of the above ranks? The appointment being one of responsibility and requiring skilled professional knowledge, you would do well to urge a British diplomated Military Assistant Surgeon for the place irrespective of rank and age.

Such appointments, if given to British diplomates, would be an encouragement and incentive to Military Assistant Surgeons as a body to exert themselves to obtain this coveted distinction, thereby improving the tone of the service—a matter you have repeatedly recommended.

Yours &c., ANOTHER INTERESTED.

HIGHLY PLACED ANGLO-INDIANS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you permit me to supplement the list of "distinguished" Anglo-Indians furnished by other correspondents in your columns for May 1898:—

Lieutenant-Colonel Forgett, C.B., Lately Commanding the Marine Battalion.

William Dracup, Assistant Consulting Engineer for Railways, Bombay.

J. W. S. Dracup, Assistant Commissioner, N. D.

W. A. Collins, Chief Engineer, R. I. M. Dockyard, Bombay.

C. W. Richardson, Presidency Magistrate, Bombay

M. T. Carroll, Manager, Messrs. William Watson & Co., Bankers.

W. Hoonahan, Deputy Collector, Karachi.

T. Ward, Messrs. Ralli Brothers.

Harry Brawn, Deputy Inspector-General of Police, Bombay (the Sherlock Holmes of India).

F. G. Dumayne, Secretary, Bombay Port Trust.

W. Bedford, Chief Superintendent, Accountant-General's Department.

J. Walsh, Superintendent, Her Majesty's Customs, Preventive Service.

W. Almon, 1st Assistant Collector of Bombay

W. B. Wright, Auditor, S. M. Railway.

J. J. Barrett, M.I.M.E., Consulting Engineer for Mills.

R. J. Sharman, Assistant Collector of Customs, Prince's Dock.

W. N. Skistone, Assistant Secretary, Bombay Port Trust.

Arthur Pantou, Traffic Manager, Bombay Port Trust.

R. W. Waller, Assistant Secretary to Government, Railway Department.

T. J. McCoughlin, Deputy Traffic Manager, South of India Railway.

W. A. Crisp, Examiner, P. W. Accounts.

F. M. Stephens, F.R.C.V.S.

C. Stephens, F.R.C.V.S.

F. L. McAfee, B.A.

H. O. F. Sealy, B.A., LL.B., Barrister-at-Law.

E. Van Der Straeten, Judge, Sheriff's Court, (Sind).

Yours &c., SPECTATOR.

PLAGUE SERVICE REWARDS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—We are all pleased to learn, from the issue of the *Record* of the 1st instant, that the attention of the Government of India is at present engaged in improving our prospects. I need hardly say that we are all very thankful for this consideration, and if I may, I would beg to observe that it would be a graceful act on the part of the Indian Government to show its appreciation of our good services during plague, famine, and particularly the recent war, by ameliorating our disadvantages on the lines proposed by the Indian Medical Association, regarding pay and pension.

Special promotion, which is usually doled out after field service, is nothing short of a great hardship to the majority who have worked ably and well; for only the very favored and small minority get it, for reasons it is unnecessary to dilate upon.

Yours &c., A MILITARY ASSISTANT SURGEON.

THE U. O. M. S.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Would you be so good as to favor me, through the columns of the *Record*, with the rules for entrance into the Unconvenanted Medical Service, and whether it is feasible for a Military Assistant Surgeon to enter it; if so, under what conditions and to whom must application be made?

Yours &c., AN ENQUIRER.

Medical Trade Notices.

VINOLIA.

BLONDEAU ET CIE, London, have submitted for our notice samples of their vinolia preparations. The samples sent comprise their vinolia liquid dentifrice, and vestal vinolia soap. The liquid dentifrice is in the form of a yellow-red fluid, with a strong and not disagreeable aromatic odour. It contains many antiseptic vegetable volatile oils, and from its behaviour when added to water apparently some sal-volatile. The dentifrice is largely an alcoholic solution, burning easily on the application of a flame, and leaving a residue in the form of pink drops which still retain a strong aromatic odour. After using it, we should say that it is of more service as a tonic and strengthener of the gums than a powerful agent for cleansing the teeth. Indeed, the makers advise the use of the dry dentifrice first followed by the liquid preparation. At all events the gums appear to be much benefited by its use, and its antiseptic powers render it a good application for use after a meal or at bed-time.

The vestal soap is the finest product among the soaps made in the Vinolia Works. It is even more soothing to an irritable or tender skin than the ordinary vinolia soap, and is superfatted and delicately perfumed. Its only drawback is its price, 2s. 6d. per cake.

BETUL-OL (KUH).N

There is no doubt that natural salicylic acid and its compounds are very much to be preferred to the artificial products. Probably many have discontinued the use of

salicylates, deterred by the occasional ill-effects caused by impurities present in the salicylic preparations made synthetically, so that the introduction of a natural compound, at a reasonable price and of undoubted purity, is a matter for congratulation. Betul-ol is salicylate of methyl made up as a liniment. The active agent is derived from *Betula lanks*, and is very similar to or identical with the oil of wintergreen obtained from *Gaulthara procumbens*, though its smell does not appear to be quite so penetrating. In the form of a liniment, as in betul-ol, it is claimed that it is readily absorbed through the skin, forms salicylate of sodium in the blood, and produces the pharmacological effects of this salt in the body, unaccompanied by any of the untoward results following upon the administration of the synthetic salicylates.

THE "ALLENBURY" FOODS.

In the artificial alimentation of infants, cow's milk has hitherto been very largely used, though the constituents are not present in the same proportions as in human milk. For instance, the proportion of Casein is too large, that of fat too small, whilst the albumin and milk sugar are deficient. The series of foods introduced by Messrs. ALLEN and HANBURY are specially prepared to meet the physiological requirements of the infant at different periods. The foods are made to resemble or to be equivalent to the milk of the mother.

What is termed the No. 1 or fine food, is specially made for infants who have to be brought up artificially from birth up to three months. It is prepared from fresh cow's milk, from which the excess of casein has been removed, cream albumin and milk sugar are added so as to bring the food up to a standard when the resulting mixture is sterilized, concentrated in vacuo, and preserved in hermetically closed vessels.

We have found this to be an excellent substitute for woman's milk for infants up to the age of three months. It is eagerly taken, readily assimilable, and particularly noted that it leads to firmness of the muscles.

From three months to seven months Messrs. ALLEN and HANBURY have a No. 2 or second food—the basis of which is the same as the No. 1 food, with the addition of maltose and of small proportion of dextrine with soluble phosphates, and when the infant has reached seven months, a No. 3 or malted food, suited to the advanced requirements for the infant, is used.

The No. 3 food is only partially predigested, so that the infant's digestive organs have something to do. The method of feeding is all important, and Messrs. ALLEN and HANBURY have introduced one of the simplest and best feeders, a bottle which can be simply flushed through and thoroughly cleansed, with a nipple which can be turned inside out so as to keep it thoroughly aseptic. These foods are not expensive, and that is a very important consideration.

ASEPTIC GLASS CATHETER CASES.

Messrs. DOWN BROTHERS inform us that they have for some time made Glass Catheter Cases on the same principle as one suggested by us, and with an improvement, viz., with rubber stopper at each end, so that the case can be well flushed out. We have pleasure in drawing attention to their statement.

KASAGRA.

The name sounds odd, and as doubts may arise as to the therapeutics of a drug with a fanciful name, we might enlighten our readers. When Extract Rhamni Purshiana (i.e., Cascara Sagrada) was first placed before the medical world, its intensely bitter taste and the gripes it caused threatened to lose sight of it as an useful dietetic, laxative and alterative; but Messrs. FARRINGTON STIMANS & Co., coming to the rescue, rid the drug of its drawbacks without impairing its medicinal value, and presented it to the public under the name of *Cascara Aromatic* which the National Formulary appropriated and caused such confusion that to prevent other preparations being further confounded with theirs, it is considered advisable to contract the name *Cascara Sagrada* into the shorter and euphonious one of *Kasagra*.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Brig.-Surgn. Lieut.-Col. W. B. Shapbiter, A. M. S., to officiate on the Administrative Med. Staff of the Army, with the tempy. rank of Surgn.-Col. *vide* Surgn.-Col. J. Williamson, deceased.

The Viceroy and Govt.-Genl. has been pleased to make the following appts. on His Excellency's personal staff.

To be Honorary Surgeons.

Surgn.-Col. W. P. Warburton, M.D., I. M. S., *vice* Brig.-Surgn. Lieut.-Col. D. D. Cunningham, M.B., F.R.S., C.I.E., retired.

Surgn.-Col. W. S. M. Price, Army Med. Staff, *vice* Surgn.-Col. C. Atkins, vacated.

Brig.-Surgn. Lieut.-Col. G. D. Bourke, A. M. S., *vice* Brig.-Surgn. Lieut.-Col. J. D. Edge, vacated.

Surgn.-Capt. W. E. A. Armstrong, I. M. S. (Mad.) offg. Bany. Surgn. and *ex-officio* Asst. to the Resdnt. in Nepal, is granted privilege leave for three months from 28th June 1898, or the subsequent date on which he may avail himself of the leave.

Surgn.-Capt. J. W. Grant, M.B., I. M. S. (Beng.) is appd. to officiate as Bandy. Surgn. and *ex-officio* Asst. to the Resdnt. in Nepal, from the date of assuming charge, *vice* Surgn.-Capt. W. E. A. Armstrong.

The services of Surgn.-Capt. P. C. Gabbett, I. M. S. (Mad.) are replaced at the disposal of the Govt. of Madras from the date on which he assumed charge of his duties under that Govt.

Surgn.-Capt. H. W. Elphick, on plague duty at Hardwar, furlough (m.c.) for six months from 20th April 1898.

Surgn. Lieut.-Col. C. J. E. Warden, I. M. S. (Beng.) Med. Storekeeper to Govt., Bengal Comd., is granted two years' furlough from the date of his availing himself of the same.

Six months' leave (m.c.) granted to Hosp. Asst. Rahim Baksh, attached to the Khedda Sahab, Dacca.

Surgn.-Major. J. C. O. Smith, Civil Surgn. from Shahjahanpur to Saharanpur dist.

The services of the undermentioned officers are replaced at the disposal of the Govt. of Beng. from the dates on which they may assume charge of their duties under Govt.—Surgn.-Capt. F. O. Clarkson, I. M. S. (Beng.); Surgn.-Capt. F. O'Kinealy, I. M. S. (Beng.)

BENGAL GOVERNMENT.

Surgn.-Lieut.-Col. D. W. D. Conlins, Insp.-Genl. of Jails, Beng., is allowed furlough for 12 months from 16th July 1898, or any subsequent date on which he may avail himself of it.

Surgn.-Capt. D. M. Moir, Offg. Presdnt. Surgn., Presg. Genl. Hosp., Calcutta, is confirmed in that app., *vice* Surgn.-Capt. E. W. Pilgrim.

Surgn.-Capt. F. O'Kinealy is appd. to be Second Resdnt. Surgn., Presg. Genl. Hosp., Calcutta, *vice* Surgn.-Capt. D. M. Moir.

Surgn.-Capt. S. K. Das, Civil Surgn. of Kalyan, is appd. to act as Civil Surgn. of Midnapore, during the absence, on deputation, of Surgn.-Maj. J. B. T. Welch, or until further orders.

Dr. F. E. May Jagannadham is appd. to be Civil Med. Officer of the Chittagong Hill Tracts; but will continue to act as Civil Med. Officer of Baranpore.

Surgn.-Maj. D. G. Crawford, Civil Surgn. of Monghyr, is appd. to act as Civil Surgn. of the 24-Parganas, during the absence, on leave, of Surgn.-Maj. A. W. D. Leahy.

Surgn.-Maj. D. G. Crawford, Offg. Civil Surgn. of the 24-Parganas, is appd. to act, until further orders, as Med. Insp. of Emigrants (Colonial Emigration) in addition to his own duties.

Surgn.-Maj. F. A. Rogers is appd. to act as Civil Surgn. of Monghyr, during the absence, on deputation, of Surgn.-Maj. D. G. Crawford.

Surgn.-Capt. J. G. Jordan, on return from tempy. milly. duty, is appd. to act as Deputy Bany. Commr., Metropolitan and Eastern Beng. Circle, until further orders.

Under Rule 6 of the rules contained in Plague Regulation, dated 2nd May 1898, the Lieut.-Govt. is pleased to appt. Surgn.-Capt. J. G. Jordan, offg. Deputy Bany. Commr., Metropolitan and Eastern Bengal Circle, to be an Asst. Health Officer of the Port of Calcutta in addition to his own duties.

Surgn.-Capt. J. C. S. Vaughan, on return from tempy. milly. duty, is re-appd. to be Deputy Bany. Commr., Western Bengal Circle, and is also placed on special duty in connection with anti-cholera inoculation.

Asst. Surgn. Satish Chandra Basu, of the Puri, Pilgrim Hosp., held med. charge of the civil station, Puri, from 21st to 26th March 1898 in addition to his own duties.

Mily. Asst. Surgn. W. Clarke appd. to act as Asst. to the Surgn.-Supdt., Presg. Genl. Hosp., Calcutta, from 5th April 1898.

Mily. Asst. Surgn. O. B. W. Bancroft is appd. to act as Med. Officer at the Sandheads, during the absence, on leave, of Asst. Surgn. P. Fitzpatrick from 1st April 1898.

Surgn.-Capt. J. T. Calvert, on return from tempy. milly. duty, is appd. to act as Civil Surgn. of Darbhanga, during the absence, on deputation, of Surgn.-Capt. C. R. M. Green.

PUNJAB GOVERNMENT.

On transfer from Umballa, Surgn.-Capt. D. M. Davidson assumed charge of civil med. duties of Murree on 14th June 1898, relieving Surgn.-Maj. A. G. Kay.

Asst. Surgn. Krishen Chand, in charge of Civil Hosp., Umballa, is placed in civil med. charge, Umballa, in addition to his own duties, from 18th June 1898, *vice* Surgn.-Capt. D. M. Davidson, transferred.

On their services being replaced at the disposal of the Govt. of Punjab, the undermentioned med. officers are re-appd. to officiate as Civil Surgn. of the 2nd class and are deputed on special duty in connection with the plague. They reported themselves at Phagware on the dates noted opposite their names:—

Surgn.-Capt. A. W. T. Buist-Sparks, 9th May 1898.

Surgn.-Capt. H. Smith, 6th May 1898.

Surgn.-Capt. G. Y. C. Hunter, 7th May 1898.

The Hon'ble the Lieut.-Govt. is pleased to appoint Surgn.-Lieut. H. J. Walton Plague Officer in the suspected areas of the Punjab.

On being relieved of the civil med. charge of the Gurdaspur dist., Asst. Surgn. Inayat-ulla Nasir reverted to Batala and resumed charge of the disty. on the 6th June 1898, relieving Hosp. Asst. Bahadur Shah.

On being relieved of the charge of Batala Disty., Gurdaspur dist., Hosp. Asst. Bahadur Shah was placed on genl. duty at the Mayo Hosp., Lahore, from 14th June 1898.

On being relieved of the civil med. charge of the Shahpur dist., Asst. Surgn. J. D. Rehbro was appd. to do genl. duty at the Mayo Hosp., Lahore, which he joined on the 18th June 1898.

On being relieved of the charge of the Newsheer Kahan Disty., Feshawar dist., Hosp. Asst. Aslam Sain was appd. to do genl. duty at Feshawar, which he joined on the 20th May 1898.

On the termination of his special plague duty in the Jullunder dist., 2nd class Hosp. Asst. Hashmat Ali reverted to his duties in the same dist. and resumed charge of the disty. on 6th June 1898.

The 1st class Hosp. Asst. having passed the examination, Prof. M.C. of Hosp. Asst. held on 15th April 1898, are promoted to the 1st class from the 2nd class against their names:—

Umar Chand, 15th April 1898; Chander Lal, 15th April 1898; Hoshan Das, 15th April 1898; Alla Baksh, 15th April 1898.

The 2nd class Hosp. Asst. having passed the Supplemental Prof. Exam. of Hosp. Asst. held on the 15th April 1898, are promoted to the 2nd class from the 3rd class against their names:—

Ghulam Ahmed, 15th April 1898; Babu Ram, 15th April 1898; Mala Lal, 15th April 1898; Waryam Singh, 15th April 1898; Bhag Mal and Amir-ud-din, 15th April 1898.

Hosp. Asst. Agia Ram, Chumian Disp., Lahore dist., has obtained 40 days' privilege leave, and was relieved of his duties on the 15th June 1898 by Hosp. Asst. Jamiat Rai, transferred from genl. duty, Mayo Hosp., Lahore.

Hosp. Asst. Nur Ahmad doing genl. duty at Kasauli obtained three months' privilege leave from 15th June 1898.

BOMBAY GOVERNMENT.

Surgn.-Lieut.-Col. J. P. Greeny, M.D., and Surgn.-Lieut. Col. D. C. Davidson respectively delivered over and received charge of the Bharwar Prison on the 29th June 1898.

His Excellency the Govr. in Council is pleased to appt. Surgn. Capt. J. H. McDonald, M.B., C.M., to hold charge of the duties of Civil Surgn.-Supdt., Lunatic Asylum and Supdt. Med. School Hyderabad, as a temporary measure, *vice* Surgn. Lieut.-Col. W. G. Henderson, F.R.C.S., transferred.

Asst. Surgn. George M. Dixon L.M. & S., has been apptd. to the med. charge of Mrs. Pascal DeSousa's Charitable Disp. at Uran from 20th June 1898.

Asst. Surgn. Pandurang Gopal, G.G.M.C., has been placed on genl. duty from 20th June 1898.

Surgn.-Capt. S. B. Grayfoot, on attaining the rank of Surgn.-Maj., will vacate the Secretaryship to the Surgn. Genl. with the Govt. of Bombay and hold permanently the appointment of Civil Surgn., Kaira, *vice* Surgn.-Maj. J. P. Barry, M.B.

Surgn.-Capt. S. H. Burnett, M.B., C.M., is apptd. to act as Secy. to the Surgn.-Genl. with the Govt. of Bombay.

Mr. J. W. P. Muir-Mackenzie, M.B., F.R.C.S., acting Chief Secy. to Govt., Revenue and Financial Dept., is granted privilege leave of absence for twelve days from the 14th July 1898.

Asst. Surgn. J. E. Bocarro, L.M. & S., and Braohji Sheriarji Bharrucha, L.M. & S., are promoted from the 2nd and 3rd to the 1st and 2nd class of Asst. Surgns. respectively, from the 8th July 1898 and 19th Dec. 1897.

CENTRAL PROVINCES GOVERNMENT

The services of Surgn.-Capt. W. Henvey, I. M. S. (Beng.), are placed temply. at the disposal of the Chief Commr. of the Central Prov.

The services of Surgn.-Capt. S. A. C. Dallas, I. M. S. (Mad.), are replaced at the disposal of the Chief Commr. of the Central Prov. from the date on which he assumed charge of his duties.

Asst. Surgn. Madhusudan Motra, in charge of the Warora Colliery, is apptd. to the civil med. charge of the Chanda dist. during the absence on leave of Surgn.-Capt. S. A. C. Dallas, I. M. S.

Asst. Surgn. S. N. J. Kotak, attached to the Burhanpur Disp., is apptd. temply. to the civil med. charge of the Dmsh dist. during the absence on leave of Mr. T. W. Quinn.

Surgn.-Major A. Silcock, M.D., Civil Surgn., Bilaspur, is apptd. to officiate as Civil Surgn., Nagpur, from 11th June 1898, the date on which he assumed charge of his duties from Surgn.-Major G. N. A. Harris, on deputation.

Surgn.-Major W. L. Price, Civil Surgn., Secal is apptd. to officiate as Civil Surgn., Bilaspur, from the date on which he assumed charge of his duties.

On being relieved by Surgn.-Capt. S. A. C. Dallas, *vice* Asst. Surgn. Krishnaji Keshavnath Gokhle is directed to do plague duty at the Wardha Ry. Sta.

On being relieved by Asst. Surgn. Krishnaji Keshavnath Gokhle, Asst. Surgn. Kishorji Mohan Das is directed to do duty under the orders of the officiating civil med. charge of the Wardha Dist.

Surgn.-Capt. W. A. C. Dallas, I.M.S., whose services have been required at the disposal of the Chief Commr. by Govt. of India Home Dept. Northcott, dated the 15th ultimo, resumed charge of his duties as Civil Surgn., Chanda, on the 22nd May last, from Asst. Surgn. Krishnaji Keshavnath Gokhle. Hosp. Asst. Abdul Bari, attached to the Jail and Police Hosp., Wardha, is apptd. to the Karamji Branch Disp. in the Balaghat Dist.

On being relieved of the charge of the Karamji Branch Disp., Civil Hosp. Asst. Bhagwant Din-Mahar, is apptd. to the Jail and Police Hosp., Wardha.

Hosp. Asst. Govind Vithal, attached to the Mayo Disp., Wardha, held charge of the Jail and Police Hosp. in addition to his own duties from the 4th to 15th June 1898, both dates inclusive.

On being relieved of the charge of the Jail and Police Hosp., Khandwa, Hosp. Asst. Ashutosh Chatterji is directed to do duty under the orders of the Civil Surgn. of Nimar.

Hosp. Asst. Ashutosh Chatterji, doing duty under the orders of the Civil Surgn. of Nimar, is directed to do duty under the orders of the Civil Surgn. of Jabalpur.

Hosp. Asst. Vithal Anand Rao and Surendranath Chakravarti, who were deputed on plague duty to the Nimar dist., directed to do duty under the orders of the Civil Surgn. of Nimar.

Hosp. Asst. Kappurajulu Naidu, doing duty under the orders of the Officer in civil med. charge Balaghat, is apptd. to the Jail and Police Hosps., Balaghat, *vice* Hosp. Asst. Jamal-ud-din, retired.

N.-W. P. AND OUDH GOVERNMENT.

Surgn.-Major J. C. O. Smith, Civil Surgn., Shahjahanpur, held visiting med. charge of the Hardoi dist. in addition to his other duties, from 3rd to 12th June 1898.

Asst. Surgn. Surosh Chander Ghose, attached to the Sadar Disp., Hardoi, to hold charge of the civil med. duties of that dist. in addition to his other duties.

Asst. Surgn. Shashi Bhushan Banerji, Travelling Plague Inspr., Ghaziabad, was on privilege leave for one month from the 15th May to 14th June 1898.

Asst. Surgn. Sri Ram from the off. charge of the Lalitpur dist. in the Jhansi dist. to that of the Kanda Disp. in Gorakhpur.

Asst. Surgn. P. N. Bonarji, Offg. Travelling Med. Inspr., Ghaziabad Circle, to the charge of the Chunar Disp. in the Mirzapur dist.

Asst. Surgn. Trishita Nath Sinha, from Balrampur Hosp., Lucknow, to Lalitpur Disp. in the Jhansi dist.

Asst. Surgn. Hari Dutt Pant, attached to the Sadar Disp. Gonda, privilege leave for two months from 2nd July 1898.

Hosp. Asst. Umald Rai, in charge of Utraula Branch Disp., Gonda dist., to the charge of the Sadar Disp., Gonda, *vice* Asst. Surgn. Hari Dutt Pant, on leave.

Asst. Surgn. E. H. Thomas, M.B., L.M.O.F. and S. Edin., L.F.P. and S. (Glas.), L.M., having completed his seven years' service in the present grade, on the 21st June 1898, is promoted to the 2nd grade from 22nd July 1898.

Asst. Surgn. Bishamber Shal, from plague inspr. duty, Ghaziabad, to the charge of Crosthwaite Hosp., Naini Tal.

Asst. Surgn. Chanan Singh, from plague duty, Haridwar, to plague inspr. duty at Ghaziabad Ry. Sta.

Mily. Asst. Surgn. M. Murphy, in civil med. charge of Mainpuri, privilege leave for two months.

BURMA GOVERNMENT.

Mily. Asst. Surgn. G. B. Gandola made over, and Mily. Asst. Surgn. T. W. Minty assumed, charge of the duties of the Civil Surgn., Mergui, on the 12th June 1898.

Surgn.-Capt. C. C. S. Barry, on proceeding on three months' privilege leave, made over, and Surgn.-Capt. O. Dyer assumed, as an additional charge, the duties of the Secty. Med. Offg., Rangoon, on the 11th June 1898.

Hosp. Asst. Mahomed Asst. relinquished charge of the Police Hosp., Bhamo, on 21st May 1898, and assumed charge of the Outpost Hosp., Bhamo, Bhamo dist., on 26th May 1898.

Hosp. Asst. F. A. Jaycela Rao relinquished charge at the Outpost Hosp., Lavelon, Bhama dist., on 35th May 1898 and assumed charge at the Police Hosp., Bhama, on 29th May 1898.

Hosp. Asst. Wasir Singh, on transfer to Southern Shan States, relinquished charge at the Genl. Hosp., Bangoon on 8th June 1898.

Hosp. Asst. Rajchunder Kur, on being placed under suspension, relinquished charge at the Police Hosp., Falam, on 17th April 1898.

Hosp. Asst. Gurudas Bawa, relinquished charge at the Police Hosp., Mogaung, on 3rd June 1898 and assumed charge at the Police Hosp., Myitkyina, on 10th June 1898.

Hosp. Asst. Pydiah Appa assumed, as an additional duty, charge at the Police Hosp., Falam Chin Hills divn., on the 17th April 1898, *vice* Hosp. Asst. R. C. Kur.

Hosp. Asst. S. S. Thumbooswamy Pillay assumed charge at the Genl. Hosp., Bangoon, on 14th June 1898.

Hosp. Asst. T. S. Salvadi Iyer relinquished charge at the Police Hosp., Katha, on the 27th May 1898 and assumed charge at the Ry. Disp., Wantho, on the 30th May 1898.

G. O. C. O.

Brig-Surgn.-Lieut.-Col. W. B. Slaughter, to officiate as Principal Med. Officer, Oudh and Rohilkhand Dist., *vice* Surgn.-Col. J. Williamson, A. M. S. deceased.

The leave granted to Surgn.-Capt. L. H. Rogers, I. M. S., in Comd. Order was extended to the 11th April 1898.

The Comr.-in-Chief in India has been pleased to sanction an exchange of places on the roster of Indian service between the undermentioned officers of the Army Med. Staff:—

Surgn.-Maj. E. H. Johnston and Surgn.-Maj. P. C. H. Gordon; Surgn.-Maj. E. Davis, and Surgn.-Maj. S. C. Philson.

ASSAM GOVERNMENT.

Sick leave for three months is granted to 3rd grade Hosp. Asst. Jadab Govinda Biswas, in extension of the three months' sick leave granted in Med. Dept. Notification, dated the 30th March 1898.

Hosp. Asst. Mangalbir Singh, in med. charge, of the Krishnai Disp., in the Goalpara dist., is apptd. to the med. charge of the Rupai Disp. in that dist., from 10th June 1898.

Hosp. Asst. Har Kumar Gupta, in med. charge of the Darrangiri Disp. in the Goalpara dist., is apptd. to the med. charge of the Gauripur Disp. in that dist. from 15th June 1898.

Babu Koteswar Guha is confirmed as a 3rd grade Hosp. Asst. in Assam from the 9th May 1898.

Babu Apurba Kumar Bose, a passed student of the Orissa Med. School, is apptd., on probation for six months, a Civil Hosp. Asst. in Assam and is posted to Dibrugarh for duty as a suppy. from 15th June 1898.

Hosp. Asst. Ram Lochan Das, in med. charge of the Rupai Disp. in the Goalpara dist., is apptd. to the med. charge of the Krishnai Disp. in that dist., 14th June 1898.

Hosp. Asst. Gobinda Chandra Das, in med. charge of the Gauripur Disp. in the Goalpara dist., is apptd. to the med. charge of the Darrangiri Disp. in that dist. from 18th June 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Re. 1 for subscribers and Re. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

MARRIAGES.

D'SYLVA—BALLARD.—On the 22nd June 1898, at the Church of the Holy Cross, Faramban, by the Rev. C. N. Bessy, Rector, Chaplain, Charles Alexander D'Sylva, second son of Apothecary F. D'Sylva, to Louisa Mary, daughter of Mr. J. W. Ballard.

VAUGHAN—SINCLAIR.—On the 29th of June 1898, at St. Andrew's Church, Darjeeling, by the Rev. C. J. Palmer, Chaplain, Surgn.-Capt. J. C. B. Vaughan, I.M.S. (Surgn.), to Dora Eleanor (Daisy), second daughter of William Sinclair Esq., of Stein Thal, Darjeeling. English papers please copy.

DEATHS.

CLIFFORD.—On 15th June, at St. George's Road, Frederick Morrison Clifford, late Surgn.-Genl., I. M. S.

YOUNG.—On 18th June, at Wilshire Road, Brixton, Surgn.-Genl. Young, M.D., aged 81

ADLEY.—On 18th June, Surgn.-Genl. William Henry Adley, of Cleddy Lodge, Haverford west, late Her Majesty's Indian Medical Service, aged 70.

LUMSDEN.—On the 30th June, Quetta, Baluchistan, Henry Arthur, the dearly loved and only son of Surgn.-Capt. and Mrs. J. S. Lumsden, I. M. S.—aged one year and six months.

BELLY.—On the 3rd July 1898, Free School Street, after a long and painful illness, Janet Clarissa, relict of the late Dr. Edward Belly, late I. S. M. D., aged 68 years and 15 days. Deeply regretted by her sorrowing children.

NOTICES TO CORRESPONDENTS.

Z. Y. K. (Manipur).—None but the holders of University degrees are entitled to use the term doctor before their names. A Hospital Assistant is certainly not entitled to style himself doctor.

A. R. (Allahabad).—(1) Your fee should be one hundred rupees. (2) Refer the matter to the British Resident of the Native State. (3) Failing to receive satisfaction put the case in the hands of your solicitors.

G. E. C. (Bandikui).—The Register ought to be out in a few days now. The dislocation of every enterprise in Calcutta, due to the plague scare, is responsible for the delay. The whole question of qualifications is up before Government. Nothing can be done in individual cases at present. Your name is registered as desired.

H. D. C. (Naini Tal).—Your name has been registered.

J. M. M. (Rajputana).—Many thanks.

Non-advertiser sends the following for publication:—
"Dr. ALICE VAN INGEN, M.D. U.S.A., L.S.A. London, Gold Medallist in Midwifery and Gynaecology (diseases of women and children), with eighteen years' experience, may be consulted at Messrs. PHILLIPS & Co., Byculla, daily (except Sundays) from 10 to 11 A.M., and at Messrs. PHILLIPS & Co., Fort, daily (except Sundays) from 9 A.M. to 9-30 A.M., also at the Dispensary, Wari Bunder Road, Mazagon, daily at 2 to 4 P.M. (except Sundays). Or by special appointment at any time. Dr. VAN INGEN resides at the Temperance Hospital, Wari Bunder Road, Mazagon, and will be willing to attend patients at their own homes. Fees moderate. Telephone any time.

Fees.—Advice at Dispensaries.—One rupee. Gratis to poor.

Calls from Dispensaries (at hours of sitting)—Two rupees.

Calls from Residence.—Five rupees.

Midwifery Engagements.—From twenty-five rupees and upwards according to patient's circumstances.

ANÆSTHESIA.

THE PRODUCTION OF CHLOROFORM ANÆSTHESIA.*

By SURGEON-LIEUT. COLONEL EDWARD LAWRIE, I.M.S.,
M.B., Edin., M.R.C.S. Eng.

Residency Surgeon, Hyderabad, Deccan.

The following are the notes of chloroform administration at the Afsangunj Hospital during April, 1898. The chloroformist for the month was Olivia Correa, a third-year student at the Hyderabad Medical School :—

1. Total number of cases chloroformed during the month, 221.
2. Cases of partial anaesthesia only for brief minor operations, 69.
3. Average age of patients chloroformed, 24 years.
4. Children below the age of five chloroformed, 48.
5. Average time to produce anaesthesia, 3 min. 2 sec.
6. Average time to produce anaesthesia in children under five, 1 min. 15 sec.
7. Average time to produce anaesthesia in adults, 3 min. 36 sec.
8. Morphine administered beforehand in cases, 3.
9. Average quantity of chloroform required to produce full anaesthesia, 295 drachms.
10. Rate in minims of chloroform applied to the cap per second, 0.96 minim per second.
11. Average total amount of chloroform employed per case, $\frac{1}{2}$ drachms.
12. Average duration of operations, 12 min. 13 sec.
13. Cases in which struggling occurred, 50.
14. After effects, vomited, 3.

The chloroformist at the Hyderabad hospitals is as a rule a fourth-year student, but this session we have been obliged to entrust the anaesthesia to third-year students as all our senior students are out on plague duty in the districts. The plan of chloroformisation we employ is that of SYME. SYME's method of giving chloroform consists in keeping the patient's breathing regular under all circumstances ; in entirely disregarding the heart and circulation as factors in the administration ; in never pushing the inhalation beyond the point where anaesthesia is complete ; and in maintaining the narcosis as long as the operation lasts at the "anaesthesia level" (*vide* diagram).

The following diagram of the blood-pressure under chloroform shows (1) precisely how SYME's method works in practice ; and (2) the effects of abnormal anaesthesia and of over-dosing.

* Reproduced from *The Lancet* by permission.

EXPLANATION OF THE DIAGRAM OF THE BLOOD-PRESSURE UNDER CHLOROFORM : THE SYMEAN READS FROM LEFT TO RIGHT.

Part I.—Normal Anaesthesia.

1. The first part of the tracing as far as arrow 1 indicates the normal level of the blood-pressure before the inhalation of chloroform is begun.
2. At arrow 1 the inhalation of chloroform is commenced.
3. Provided there is continuous regular breathing the blood-pressure falls gradually until anaesthesia is complete at 2. The fall of blood-pressure up to this point is due to vaso-motor dilatation and is perfectly harmless.
4. When the point indicated by arrow 2 is reached and anaesthesia is complete, which is known clinically by the cornea becoming insensitive or the breathing stertorous, the inhalation is stopped and only sufficient chloroform is given afterwards to maintain the blood-pressure as nearly as possible at the "anaesthesia level."

Part II.—Abnormal Anaesthesia and Overdosing.

5. The dotted lines in the diagram show what happens when chloroform is given with too little air or in such a manner that the patient's breathing is interfered with. The blood-pressure falls irregularly and with sudden deep drops which used to be thought by the Glasgow Committee to be caused by sudden heart failure. Dr. BOMFORD discovered that these sudden falls are due to nervous agency through the vagus which, when overdosing is threatened, temporarily stops or slows the heart as a safeguard against the over rapid conveyance of the anaesthetic to the brain. Whether they are safeguards or not, these irregular falls ought never to be brought about, as they carry the blood-pressure below the "anaesthesia level" and are abnormal. The danger of irregular respiration is that it may lead to the inhalation or gasping in, of irregular quantities of chloroform and render overdosing imminent.

6. If chloroform is pushed beyond the point where anaesthesia is complete the respiration becomes unimpeded and the heart begins to fail. At arrow 3 the breathing ceases ; the pulse fails at 4 ; recovery is then almost impossible, and the heart stops at 5.

(The more the air is excluded when chloroform is pushed, the more rapid and irregular will be the failure of the heart and circulation. Undoubtedly the pulse will show signs of this, but it can never convey more than second-hand information that the breathing has been interfered with or that the patient has been overdosed, for both of which, clinically or experimentally, the chloroformist is alone responsible.)

Proceeding on SYME's plan the administration of chloroform is never pushed below the "anaesthesia level." It is obvious that the region of danger is not entered or even seriously approached, and that unless SYME's rules are accidentally disregarded no risk whatever from chloroform anaesthesia can ever arise. On the other hand, those who believe that chloroform has a direct action upon the heart must be guided more or less by the pulse, which is to them an index of unavoidable danger and necessarily one to be anxiously watched. But the experiments of the Hyderabad Commission and

my own circulation experiments have long ago proved that chloroform has no direct action on the heart. Accordingly, the moment the circulation is made a principal factor in the inhalation and is watched for effects which can only be produced indirectly through the respiration, an appreciable element of peril is introduced which makes the method of administration itself more or less homicidal. This must be clearly understood. It is not only that "watching the pulse" distracts some of the chloroformist's attention from the all-important breathing, but it is manifestly useless to watch it at all except as a danger signal, and as a danger signal it can only be brought into action by conditions for which the chloroformist is himself responsible, such as abnormal administration with too little air, or overdosing. The measure of heart failure under chloroform is demonstrably the exact measure of the amount of the chloroformist's attention which is withdrawn from the breathing and bestowed upon the pulse; and the diagram proves that if the pulse were to be taken as the sole guide to dosage the administration of chloroform would not only never be free from risk, but would of necessity be uniformly fatal. What is shown so definitely and admirably in the diagram is fully borne out in clinical practice. In Hyderabad chloroform is given by students in strict accordance with SYME's principles, the heart is ignored, and we have no deaths. In England the teaching of anaesthesia is in the hands of professional anaesthetists who "funk" the heart and deaths from chloroform take place, according to LEONARD HILL, by the dozen and, according to ROGER WILLIAMS, no less than once in every 1236 inhalations. The death under anaesthetics in England represent an appalling picture of the incapacity of the medical profession as regards the administration of these drugs. This incapacity is altogether due to the absolute want of training of English students in the art of chloroform administration on SYME's principles, which have been established on a scientific basis by the Hyderabad Commission. We, at Hyderabad, have always said that if students in India can be taught to give chloroform with guaranteed safety, *a fortiori* the splendid men who study in the London medical schools with all their superior advantages can be taught to do the same.

—:—:—

A METHOD OF ARTIFICIAL FEEDING OF INFANTS.

By HENRY HUDSON, M.B.C.S., L.R.C.P.,
Wesleyan Mission, Manargudi.

THE artificial feeding of children in India, especially of European children, is beset with even more difficulty than in a temperate climate. The following method, lately written out at the request of a friend for his own guidance, does not profess to be the best method for every child. It has, however, been found to be successful and practicable in the case of one of my own children; and possibly concise directions may be useful to other practitioners who have not had special occasion to adopt well known principles of dieting infants to Indian conditions.

The directions pre-suppose a somewhat weakly child, whose case is not suited by the ordinary and easier

1 Hyderabad.

methods, such as simple dilution of breast milk. The practitioner may of course in individual cases see reason to modify proportions, or may find that some other method suits equally well and is more convenient; any intelligent mother or nurse, however, can be made to understand and carry out this method.

The most satisfactory plan is to use a steriliser not only because the child has thereby a better chance, but also because its use lessens trouble. For a journey it is a great convenience to sterilise 24 or 48 hours' supply of ready-mixed food. Sterilisers for milk are sold by the instrument-makers; but the essential parts are simple enough in construction and could be made cheaply, especially from a copy, by an intelligent tin-man in any ordinary bazaar. However, these directions do not pre-suppose the possession of a steriliser. Sterilising milk is said to destroy or diminish its antiscorbutic properties (*vide Lancet*, 1st January, 1898), and should therefore, not be done unintermittently for months.

Take of	Cow's milk (fresh or boiled), the top creamy part, one ounce by measure.
	Whey, prepared as below, one ounce by measure.
	Sugar of milk, 15 grains, about $\frac{1}{4}$ a small teaspoonful.
	Lime water, $\frac{1}{2}$ to one teaspoonful.

Give this mixture at blood-heat in a perfectly clean boat-shaped bottle with a clean teat. The child will probably not take all. To prepare the whey. Add a teaspoonful of good essence of rennet (*e.g.*, Croese and Blackwell's) to a large tea-cupful of milk at blood-heat (*i.e.*, about 98°, neither hot nor cold). Let it stand for an hour, when, if the rennet is good, it will have set to a junket. This will keep good on the plains for at least 12 hours. Take three or four heaped teaspoonfuls of the junket, or sufficient to form one ounce of whey, boil these three or four teaspoonfuls, and then carefully strain out all the curd through a piece of clean cloth. Dissolve the sugar in the hot whey, and add the mixture of sugar and whey to the milk.

The above mixture is suitable for a child three days old. During the first 12 hours little or nothing should be given; during the next 24 hours the above mixture with the addition of two or three teaspoonfuls of warm water may be given every four hours. The interval should then be gradually lessened till the child on the third day is taking the mixture, without any addition of water, every two hours during the day, and every two or four hours during the night.

Towards the end of the first month the quantity of food given at a time should be gradually increased, and at the same time the proportion of milk increased.

If the child passes undigested curd, the proportion of milk must be lessened. If the child is constipated, the lime-water may be diminished, constipation is sometimes righted by decreasing the proportion of milk, or by gentle massage of the abdomen with oil.

The mixture must be prepared freshly each time, unless a milk steriliser is used. For sugar of milk, white lump sugar may be substituted, but the natural milk-sugar is preferable, especially until the child gains strength.

Towards the end of the first month, and sometimes even earlier, the addition of not more than a small tea-

...of Mellins' (or some other mother's) food is sometimes useful. It must be thoroughly dissolved in the whey. At this stage Mellins' food is not to be looked upon as suitable nourishment for the child. It may be added often with great advantage when (1) there is constipation, (2) when owing to the child's inability to digest even the amount of curd contained in the milk and whey mixture, it is not taking a sufficiently large proportion of milk. Usually lime-water will not be necessary when Mellins' food is used. The latter is slightly alkaline, and slightly laxative, and helps to keep the cow's milk from forming into stiff curd.

The best guides as to whether the food is suiting are, (1) increase of the child's weight; (2) the passing of the normal mustard-like motions, free or nearly free from white lumps of undigested curd. Occasional vomiting need excite no alarm. It must be remembered that the child normally *loses* weight for the first two or three days.

If the child persistently passes curdy, frothy, green motions, and suffers from colic and straining, drop the milk altogether and give only whey and sugar, for a day or two; then gradually return to the milk again. If the mixture still does not suit, substitute cream for the milk and gradually return to the milk again.

During the *second month* and often earlier than this, the proportions may be gradually altered to milk, two ounces, and whey, one ounce. During the *third month*, it is useful to add a gradually increasing quantity of Mellins' food. This should certainly not exceed two teaspoonfuls till the third month is passed. At six months it may be given more freely.

—o:—

SOME SURGICAL SINS.*

By EMORY LANPHEAR, M.D., PH.D., LL.D.
St. Louis, U.S.A.

THERE are a number of "sins of omission as well as of commission" which surgeons may well pause to consider. Let no man lay flattering unction to his soul and say: "This is not for me." Wait and see! Profiting if there be ought to censure in your work.

First Sin.—Operating on Hopeless Cases.—There are some—and they are called surgeons—who will undertake almost any kind of an operation regardless of the prospects of cure or failure, nay, even of life or death; and sometimes without consideration of the question of their ability to do the work properly.

The incentives are: (a) to get a good fee; (b) to have the credit of operating, especially in rare or difficult cases; (c) to obtain control of the influential patient from a conservative physician who, recognizing the hopelessness of the case, is doing all he can to ameliorate suffering and prolong life, but persistently refuses entreaties of patient and friends to "do something"; (d) ignorance of the real condition.

The objections to operating in cases well-known to be hopeless are: (1) It is wrong. The doctor who will operate upon a case merely to secure a good fee, knowing perfectly well that death will follow, or that no benefit will be gained, is no better than a common thief! And

the surgeon who will, under the circumstances, operate before a class merely to demonstrate the technic of the operation and show his own adeptness, is little better. Yet I have heard a "professor" in one of the schools of St. Louis confess to this practice. (2) It brings discredit upon surgery. Therefore, I plead for (a) more careful examination before operation, (b) more thorough diagnostic and prognostic skill, (c) more judgment in the selection of cases; for I am charitable enough to believe that most operations upon hopeless cases are performed, not through desire of notoriety or gain, knowingly to the detriment of the patient, nor yet as an attempt, to gain an advantage over a rival, but through ignorance of the actual condition and of the prospects for recovery after operation; indeed, I, myself, must plead guilty to having been indiscreet in the selection of cases in the enthusiasm of my early work. Verily, wisdom increaseth with age—and experience. (3) It prevents other patients with similar disease from submitting to operations clearly indicated. I recall an instance in point: I was called to Nebraska to remove a cancerous breast; it was too far advanced to cure; operation could but hasten death and increase suffering; I refused to do anything; after my departure the doctor amputated the breast without entering the axilla (1) and the woman died in six weeks. A lady upon a neighboring farm whom I saw at the same visit had a scirrhus of the breast just developing, almost consented to extirpation, waited, and was lost; she was "scared out" by the death of her friend; another life sacrificed through ignorance.

The diseases in which this mistake is most liable to be made are (a) appendicitis with perforative peritonitis; (b) cancer of the breast; (c) hip-joint disease; (d) malignant affections of the uterus; (e) severe, acute trauma where waiting a few hours would determine the question of life and death.

Second Sin.—Delaying Opinion as to the Gravity of a Disease.—This applies particularly to cases which the attending physician knows full well tend to a fatal termination if not subjected to early operation; yet he hesitates to tell the patient the character of the disease and the necessity for surgical treatment—waiting, tinkering, giving medicines, encouraging the patient with false hopes—hopes, he admits, based upon bubbles thin as air; but still waiting, ever waiting—for what, God alone knows. I never have been able to fathom such men, to determine why they temporize, too often until too late. One would think them few, but this is not true. Such men are numerous—I meet them quite frequently. Only a few months ago a physician brought me a case of cancer of the uterus from the Indian Territory, far advanced, stinking, yet still operable. He was well informed, a graduate of one of our best colleges; had treated the case for some months, recognizing its malignancy all the time. Yet he begged me not to tell the patient what was the trouble. He had informed her that a simple little operation would have to be performed for her "ulceration of the womb"—a "simple little operation:" hysterectomy! Well, I told her of her condition and of the prospects with and without operation, and let her decide. She submitted gracefully, and was sent home in three weeks relieved of present danger, possibly cured.

*Reproduced from the *Medical and Surgical Reporter* by request.

...in an acute inflammation for a long time, his opportunity when the patient did not ... for his death, and his forgiveness for my ... an account of the prompt recovery of his ... Each episode is not at all uncommon. They ... chiefly in connection with (1) uterine fibromata, (2) cancer of the uterus, (3) cancer of the breast, (4) amputation—for septic wounds, osteomyelitis, tuberculosis, etc., (5) appendicitis, and (6) opening of purulent accumulation as (a) empyema, (b) psoas abscess, (c) cold abscesses of the neck, (d) pus in the joints, etc. I might dwell much longer on this topic but—*verbum sat sapienti*.

Third Sin.—Failing to Operate in depressed fractures of the skull.—Until quite recently it has been the teaching of schools to leave all fractures of the skull severely alone, unless some grave symptom demanded operation, regardless of depression. This was because there was more danger (before the days of antiseptic surgery) in opening up wounds of the head than in leaving them alone. And in these degenerate days, when even a JOSEPH LISTER takes a pocket case from his pantaloons, removes a knife, automatically dips it in carbolic solution and proceeds to operate, I am not sure but the old doctrine is still a pretty good rule to follow—for some operators. Indeed, I have recently seen some American surgeons who pretend to be moderately clean (more of which later) that I would not trust inside of my head. But presuming that every community now has at least one physician sufficiently familiar with antiseptics to keep his professional brethren of the neighbourhood from picking his instruments out of the solution to examine their construction (a thing that not infrequently has happened to me, and not always in the country, either), I must insist upon the future observance of AGNEW's rule: "Every depressed fracture of the skull should be operated upon regardless of the amount of depression and irrespective of pressure symptoms." The reason for this is that nearly 50 per cent. of serious injuries to the frontal region, when not trephined, terminate in epilepsy or insanity; nearly all of which sequela can be prevented by operation at the time of accident. It is not good practice to wait for the nervous system to arise and then operate. The way to cure traumatic epilepsy is to prevent it; also, traumatic insanity.

But many men do not do this, especially in the country—why, I do not pretend to say. Timidity perhaps, possibly a fear of censure if the patient dies after operation; and of legal complications in accidents of homicidal origin. The latter often deters surgeons, oftener than justifiable, in all sorts of injuries—not to the head alone. And there are probably other reasons. Be that as it may, I know that many cases of depressed fracture are still left untrephined, for I meet such cases quite often and recent ones too. Doctors are too afraid of urging operations in such cases in opposition to the wishes of relatives and friends, and continue in charge of the case in spite of the whisperings of conscience that a wrong has been done in not insisting upon operation or quitting the case. I have little respect for the man who has not the courage to live up

...and of course, that of ... in a general sense for a ... skull isn't raised, and the ... didn't dare, remains in charge, and an insanity is put to the ... settlement in the great hereafter. Let me ... a case in point.

P. G. was 52 years of age at the time of the accident. Some four years before he came under my care he was kicked upon the forehead by a mule. There was a marked depressed fracture of the frontal bone in the median line just at the margin of the hairy scalp; but as he fell into the hands of a "conservative" surgeon who believed that a depressed fracture should not be operated upon unless profound symptoms of pressure are present he was not trephined, because he was unconscious but a few moments, and very soon went about his business as if the injury were of no consequence. If a progressive modern surgeon had been called, who believed that every depressed fracture of the skull should be subjected to operation at the time of injury, however slight the depression, and irrespective of pressure symptoms, the most disastrous consequences might have been averted; for very soon a most remarkable change occurred in the patient. Before the accident he was an exemplary husband, and devoted father; a strong opponent of intoxicating liquors and a Christian gentleman; noted for his integrity and excellent character. But soon it was seen that his character was totally changed—he deserted his wife and sought the companionship of prostitutes; he was so abusive to his children when at home that they fled from him in terror; he became so addicted to the use of whisky that he soon wasted his property and sunk to the level of the drunken sot as often found in the gutter as in bed; he cursed and swore and seemed to lose all sense of manhood and decency—he was obscene, vulgar and debased. This condition continued for a period of more than three years with occasional intervals in which it was thought he was going to "reform;" finally, after a long debauch, suicidal and homicidal impulses became predominant, and at last the relatives consented to operation. Upon removing the depressed bone a large fragment of the vitreous plate was found projecting through the dura an inch or more into the frontal lobes. The superior longitudinal sinus was crushed and filled with organized blood clot, and much of the middle frontal convolutions showed signs of pressure but no decided degeneration. There was little shock and no meningitis following this extensive operation. A marked quietness instead of constant restlessness was the first change noticed in the mental condition; the countenance became more serene, the voice less coarse. As convalescence progressed, it was found that the patient was more like his former self—he greeted his wife and children with a pleasant smile and kind words instead of scowls and curses. And when bodily health was completely restored he became his old self once more; gentle, affectionate and trustworthy. This improvement was not temporary. More than two years have elapsed, and his mental condition is as good as before the accident. He recalls the incidents of his mad career as one remembers

...the terror of the past in the present
...the terror of the past in the present

Now here was a triumph of surgery, to be sure. But supposing this man had not fallen into the hands of one who could restore him; or that he had died while yet in his iniquity? If what the theologians tell us be correct, would not the doctor who failed to do his duty be held responsible for this soul's eternal torment? But—religion aside—from a purely ethical standpoint, has a doctor the moral right to commit this "third sin?"

Fourth Sin.—Pretending to be Clean, But Failing.—Every one now knows the incalculable value of asepsis; most surgeons pretend to practice it; nearly all fail. The clean (ideally, surgically, truly clean) surgeons of America do not number a dozen! I know them—I mean the leaders of the profession, not the hewers of wood and tillers of soil, not the common, everyday workers like you and me, but the men to whom we look for guidance. Why, I saw a "professor of surgery" in one of the leading schools of America, not long since, making a thyroidectomy before his class; his spectacles fell into the wound; he picked them out, deliberately readjusted them and went on about his work as if nothing had happened; and in reporting the case subsequently he wondered why he had pus in the wound—yet he would be scandalized if I were to assert that he doesn't practice aseptic, modern surgery! He thinks he does. It is just that kind of men who commit this "Fourth Sin." They are the men I am after, and they are not confined to America, either. England has but few men who are doing ideal work, and the continent is nearly as bad—or it has changed wonderfully since my last visit. The points of failure are—

(1) Dirty finger nails. LAWSON TAIT's remarks that, "the high mortality rate in abdominal surgery found in the work of German surgeons is easily accounted for—they don't clean their finger nails," is applicable to the methods of some surgeons not Teutonic. Too many operators simply scrub their hands for a few minutes, wipe them upon a towel, wash in bichloride solution for an instant, and then proceed to operate.

Doctor! Does that apply to you? Now you know well enough that after carefully scrubbing your hands for several minutes you ought to dry them and closely trim the nails; then scrub with much soap and muscular energy for five minutes more and then sterilize them by (a) immersion in alcohol for at least two minutes, and then washing in sublimate solution, or (b) washing in saturated solution of potassium permanganate until hands and arms are of a mahogany color, decolorizing in a saturated solution of oxalic acid, and finally rinsing in sublimate solution 1 to 1,000, and then in boiled water. You know you ought to do this before every laparotomy (abdominal section), trephining, thyroidectomy, resection of joint, etc.—but do you do it? If not, you are guilty and need censuring.

(2) Carelessness in touching clothing, table, pulse of patient, handle of pitcher, etc., during an operation, and then going on without further washing, is entirely too common with those who are perfect in their methods of preparation. One of America's greatest teachers, writers

and operators—a man of whom we are all proud—has to be constantly watched by his assistants in regard to his department of the "fourth sin." In his enthusiasm, he forgets his own precepts. "To wit is human." There is some satisfaction in knowing that Missouri does not have all the sinners. We all should be more particular about contamination of our hands and instruments during capital operations.

Eternal vigilance is the price of—asepsis.

(3) Carelessness in keeping and handling gauze. (a) It is too common a practice to keep dry gauze wrapped up in a paper which is hurriedly unrolled and handled with dirty fingers in cases of haste. If kept dry, a necessity with the iodoform variety, it should be rolled in aseptic, oiled paper, and placed in a tin box or glass jar which closes tightly, and occasionally re-sterilized by heat. Preferably, gauze should be kept in a glass jar in sublimate solution; tightly closed, and a dirty hand never trust down after a piece. I myself, keep two jars—one for dressings for pus cases, of which I am not so careful; the other for operations and aseptic dressings—from which the pieces are taken by means of a pair of forceps, sterilized by passing through the flame of an alcohol lamp before insertion in the jar. (b) Gauze is too often cut with scissors not sterilized, especially in making dressings. I know a surgeon of more than local reputation who invariably cuts his gauze for dressings with scissors taken from his velvet-lined pocket case; and he is a teacher, too. But that does not make it right. (c) Allowing assistants or nurses with suspicious hands to cut the gauze is just as bad. I recently saw a "trained" nurse in a hospital assisting at a removal of the breast, she was cutting gauze for "sponges"—moved the slop-jar under the table for the surgeon, handed the other can to the anesthetizer, and continued cutting gauze without a thought of washing. Such cattle ought to be taught the value of the Hindoo proverb. "Cleanliness is the key to heaven."

(4) Improper selection and management of instruments. (a) Those without metal handles—so that sterilization by boiling or otherwise is impossible; (b) those with old-fashioned points—so that perfect cleaning is unattainable; (c) failure to scrub and boil all instruments immediately after operation in septic cases.

Fifth Sin.—Under charging, in Order to Secure an Operation.—This is a sin too often committed by men who stand high in the profession; and this assertion is no idle figment of the imagination, either. As a young man, I am often compelled to bear the brunt of the sins of older men. For example, a physician in Northern Kansas made all arrangements for me to operate for an ovarian tumor; a banker's wife; fee agreed upon \$500. The patient arrived at the hospital during my temporary absence from the city; banker "accidentally" fell into conversation with another, an older surgeon, who remarked that \$250 was his (or to be charitable, perhaps, he may have said the) usual charge for such an operation; banker, on inquiry of nurses, physicians, etc., found this man to be "the best surgeon in the city," and he was \$250 "ahead," I was \$500 "out." Many such experiences have been mine; 'tis the fate of the young and the meek.

His doctor.—but this isn't a doctor, and really is not supposed to teach anything, except, perhaps, patience—which, like the poor, the young surgeon must have always with him.

Sixth Sin.—Stealing Patients from Other Surgeons.

This is more often the cause of hard feelings between surgeons than any other one thing, though, as it is done usually in such a general, "ethical" way there is no recourse left to the injured party except to growl. Occasionally one, with more enthusiasm than discretion, "prefers charges"—which come to naught. But sometimes the bitter is bitten. I recall an instance. I had made all arrangements to operate in conjunction with a distinguished surgeon of Memphis, upon a southern lady who had a very bad pyosalpinx; now, in the city where she was stopping there was a surgeon who had made a number of sections without a death and was very ambitious to reach the magical fifty cases without a death, beyond which world-wide fame is supposed to lie; he hearing of the case, managed to be introduced, and with an eloquence worthy of a better cause, persuaded her that he was the only man that could do the work well; he actually took her in his own buggy as he left, carried her to the hospital and operated upon her without any preparatory treatment, and without waiting to consult her husband, who had left the city for a day, the patient died a few moments after removal from the table, the surgeon "broke his record," received not a dollar, and made an enemy of the husband—but, as for me I am his friend still; it was simply a little professional indiscretion, bred of enthusiasm on his part. But there are cases of genuine pure, unadulterated stealing, "too numerous to mention," as the auctioneer says, and too vexatious to repeat.

Seventh Sin.—Representing Capital Operations as "Trifling."

—In order to secure consent to operations some are inclined to belittle the dangers, represent the work as "trifling," etc. Of course I do not now refer to instances where there is good reason for not going into the details with a patient, explaining danger to such a degree as to cause refusal to consent to an urgent operation. Such cases are quite often met; and the explanations must be made to the friends, not the patient. But to gross misrepresentation or, at least, to the deception of silence as to the dangers. Once I was guilty of this sin, it was several years ago—when I was just entering upon my surgical work. I had a streak of good luck, had made some thirty or forty abdominal sections without any bad results, and I thought I could do anything in pelvic work; in my over-confidence I committed the "Seventh Sin," once more demonstrating the truth of BYRON'S words: "But ignorance must ever be a part of sin." A beautiful girl was brought to me from Southwest Missonry, with tubal abscess, double; she questioned anxiously if there were danger in removal, and I assured her there was none. I removed the tubes, secure in my faith in my own works. I knew not that I tore into the rectum in separating adhesions; she died of peritonitis—never uttering one word of censure, but oh! that look upon her face as she passed into the realm of shades! Then I felt indeed the grievousness of my sin. I believe I shall never again operate upon a patient except in emergency, without fully explaining the possibilities of the

case with and without operation, leaving the choice to her. And this is right.

Example teaches better than precept. One of our surgeons of international reputation had as a patient one of the wealthiest women in the city, ovarianitis chronic. She was doing well under medical treatment and would have remained a semi-invalid to the end of her days, but was ambitious to be well, as became a leader of society. The doctor was likewise ambitious—to be known as an abdominal surgeon, and so he tempted the woman with hopes of health. He said: "Removal of the ovaries is a very simple, little operation: some morning I'll bring my table, my nurse and my assistants and we'll take out these little troublesome things and make you well." "And is there no danger, doctor?" "None in the least, madam." And she consented. Oophorectomy was performed. The next day the doctor left town for twenty-four hours. Patient developed peritonitis, called another surgeon, and was told next morning she had but a few hours to live. She prepared a surprise party for her physician. When he returned to town he hastened to her home and there found some twenty or thirty ladies, the most prominent and influential in his practice, gathered at the bedside. The lady reaching out her hand seized his in a grasp not to be shaken off. Calmly, amidst profoundest silence she spoke: "Dr. —, I was a happy woman, an invalid to be sure, but happy in the love of relatives and friends, surrounded by all the comforts and luxuries that wealth can provide, not suffering much though wanting health. I could have lived for many years in the peace and happiness of my family. But in an evil hour you came and sang the siren's song. You told me there was no danger. Now I have peritonitis—am dying by your hands. Do you deserve further confidence or success? No. I have called your friends to hear my last words to you. With a dying woman's breath I curse you. Go!" As she flung his hand from her he went—and his business went also. Need more be said?

Eighth Sin.—Keeping Patients too Long Under Chloroform.—'Twas the ambition of surgeons prior to 1846 to operate rapidly; he who could most quickly perform an operation was rated the best surgeon; in celerity was success and reputation. But with the introduction of anesthesia the other extreme became more and more popular until today the whole city of New York does not contain a half dozen operators who insist upon speedy work even in the abdomen. Many indeed say: "It does not matter how long the belly is open if one is clean and the room is warm." Fatal error. Nowhere in surgery is haste more necessary than in abdominal and pelvic work; the man who can most quickly open the abdomen, do his work rapidly, yet well, and close his wound with least delay is the one who will have the best mortality rate and in spite of the fact that he does operations that the slow man would not dare to attempt. The advice of a great operator against ruptured tubal pregnancy is aptly: "Get into the belly as soon as you can, but for heaven's sake get out."

Beside the danger of long-continued exposure of surfaces liable to be infected, with consequent sleep-

these results, there is the greater one from the anaesthetic itself. We have been wont to ignore this; with impunity from pain and perfect quietness, we forget that at every operation, however small, in which chloroform or ether is given, our patient is literally carried to "the valley and shadow of death," and though he oft apparently returns in safety, in a few hours may pass beyond. "Shock" is usually due; to (1) excessive hemorrhage; or (2) prolonged anesthesia, and many a death certificate has been filed in with "shock" when the real cause of death was too much chloroform or ether. Nor is this danger all. Even though the patient recovers from the immediate influence, if he has been kept too long in complete narcosis the remote effects upon the nervous system may be profound and lasting. As WHEATON says:

"There is little doubt that anesthesia is responsible for this adding of weeks, months, and perhaps years, of suffering and woe and that many a tortured nervous system lives to-day to testify to the truthfulness of this statement."

In doing our operative work we should, therefore, ever bear in mind "Ariston metron"—the golden mean—the middle course is best; not using undue haste at the expense of safety nor keeping our patient too long under the ever pernicious influence of anesthetics. Unwise speed is bad; "chronic surgery is worse."

—10—

THE DANGERS OF RECTAL OPERATIONS *

By JOSEPH M. MATHEWS, M.D.

Professor of Surgery and Clinical Lecturer on Diseases of the Rectum in the Kentucky School of Medicine; Rectologist to the Kentucky School of Medicine Hospital and the Louisville City Hospital, &c.

WERE a patient to ask: Is there any danger in operating for internal hemorrhoids? You might likely very flippantly reply. "No, there is no danger." At the Cincinnati meeting of the American Medical Association, I reported 2,000 operations for hemorrhoids without a single death; but on my return from that Association I lost a beautiful woman from the simple operation for internal hemorrhoids. If you lose one patient in 2,000 you cannot say that the operation is devoid of all danger, since there is always the risk of (1) hemorrhage (2) sepsis, and (3) contraction of the anal orifice.

Not long ago a man died during the night from hemorrhage after he had had a couple of internal piles ligated at the Louisville City Hospital and even the great authority Dr. SAMUEL D. GROSS reported a similar experience. True it might not happen once in 500 operations; but there is always the risk of inadvertently dividing a very important artery while making the incision for the legation method of removing piles. If seen in time twisting, torsion, pressure, application of hot water, &c., may staunch the bleeding, but it is quite possible that the bleeding point may escape discovery till too late to check it.

There is a great distribution of nerves and lymphatics around the rectum and no matter how small the incision

round the base of a pile, it is still an exposed wound in which a septic condition may ensue either from inflammation or from the passing of fecal matter.

On one occasion, I ligated seven large hemorrhoids in a young lady. Good recovery followed; but 10 days after I had discharged her, her father came to me saying that though she had taken purgatives, &c., and desired to go to stool, her bowels could not be moved. On examining her I found that the hemorrhoids had sloughed off, and the surface of their sites had united completely, and absolutely so as to totally occlude the anal orifice. As there are traumatic strictures not involving the sphincter and all that is required is to introduce the speculum or dilator and break down the adhesions.

Simply dividing the main channel will never effect a cure in many cases of *fecula in ano*, where you have to search with your probe for additional channels which often run in all directions and sometimes in close relationship to the urethra or perhaps under an important artery distant from the anus. Division of the main tract in such cases is dangerous, by reason of injury to adjacent structures or organs, but chiefly by division of the sphincter muscle which refuses to be repaired, and you have to choose between finishing your operation or not. I would much rather do a half-way operation and fail to cure the *fecula in ano* than divide the sphincter and condemn the patient to life-long fecal incontinence. Never stretch an incomplete or crippled sphincter during the operation and above all never divide that muscle more than once. There is no sense in dilating, stretching or breaking the sphincter previous to laying open the fistula, as you will have to divide the sphincter muscle in doing the operation for fistula.

Whenever you hear of a protrusion from a child's anus, make up your mind that it is not piles. Children, up to 14 years of age do not have piles. It is either a prolapse of the rectum or it is a polypus, which (latter) is a tumor attached to the mucous membrane or the walls of the gut by a pedicle which is usually 0.5 to 1 inch long, but may grow to seven inches in length. The usual procedure is to twist the polypus off the pedicle and its included artery, sometimes a good sized artery—but you can never exactly tell whether you have twisted sufficiently or not to prevent hemorrhage after the polypus has been torn away. If the pedicle is long, lax and tough enough to bear tying, certainly do so, but remember there is always the danger of the ligature cutting through the stump of the pedicle and letting the patient bleed to death: Especially if the pedicle be attached high up (two to five inches away) and the base of attachment is not only beyond the reach of the clamp-forceps but also may not be easily recognizable. The best thing to do in such a case is to dilate the rectum well and pass a plug (made of iodoform gauze wrapped round a hard rubber tube) as high as it will go and removing the speculum let the gut grasp the plugs, which should be soaked in a solution of persulphate of iron (diluted half-and-half with water) or diluted Monsell's solution.

Capillary piles are very dangerous as they bleed vigorously and are often so high up as to puzzle many a physician as to the true source of the excessive hemorrhage. You may open the anus and see neither

* Report of a Clinical Lecture delivered at the Kentucky School of Medicine Hospital.

hemorrhoids nor protrusion of the bowel, but you will find a congested condition with exposure of an artery which is the cause of all the trouble. This bleeding must be stopped. This is done by plugging the patient's anus with iodoform gauze soaked in a five per cent. solution of MONSIEUR, wrung out half dry and deposited just inside the rectum so that the anus will grip and maintain it in position after the speculum or dilator is removed. Give the patient a morphia hypoderm, repeated *S. O. S.*, in an hour or two. As the action of the rectum will expel this plug within 20 minutes if left to itself, get the patient herself, or a nurse to keep her hand tightly against the rectum for at least one or two hours, by which time the pain will have vanished and the bleeding ceased as well as the patient cured. Thus proving beyond all doubt that the hemorrhage came from the lower end of the rectum and not from above as there is no condition of the colon save that of cancer, that would cause the loss of a pint of blood. I do not agree with those persons who say that an ulcer in the upper part of the rectum, or in the colon or in the sigmoid flexure must cause the hemorrhage, as an ulcer is a pathologic condition with a deposit of fibrin or lymph which prevents, not promotes bleeding. There are cases where an abrasion or injury to the bowel by a hard piece of fecal matter or something of that sort might cause hemorrhage, but such cases are rare indeed, and even then the bleeding can, in 99 per cent. of them, be stopped by simply plugging the rectum with iodoform gauze dipped in MONSIEUR's solution.

Lastly, always apprehend a violent hemorrhage in dealing with a rectal stricture, which is benign in its nature and it is a great mistake to think that a constriction of the sphincter through which you can pass your finger only—with no ulceration above—is a simple stricture easily reached, easily handled and easily treated, for the real operation for such a condition is either division or breaking of the stricture with considerable danger.

GUNSHOT INJURIES AND MODERN PROJECTILES.*

By HENRY J. DAVIS, M.A., M.D., B.C. (Cantab.)

Late Surgeon, National Fund for Greek Wounded and late House Surgeon to St. Thomas' Hospital, London.

ALL bullet wounds, except those limited to the soft structures, result in compound fracture of bones, or as Sir WILLIAM MCCORMACK puts it, a bullet wound is "an extreme form of contused wound combined with the dangerous depths of a punctured wound" whose, (1) hygienic surroundings are invariably bad while the wound is, (2) an infected one, (3) devoid of drainage owing to the long sinus left by the track of the bullet. Shell wounds, on the other hand usually result in extensive lacerations of the soft tissues, with perhaps comminution of the bones as well.

The Martini Henri, Enfield, Le Gras, Mauser and Lee-Netford are the types of rifles chiefly used in European warfare. The disadvantages of the Martini rifle when compared to the present magazine rifle is that it "kicks"

hard and does not repeat, and the cartridges are heavy to carry, but for all that it is a deadly weapon whose "kick" does a great deal of damage and can sooner stop the march of an enemy than can the projectiles of the majority of the 'repeating arms.' Conical bullets never make the wounds that round balls do, but the trajectory is flatter, they carry straighter and kill at a greater distance. The velocity of the Mauser bullet is something terrific—being effective up to 4,000 yards, but it does little damage, compared to the Martini which, when it strikes a bone such as the femur, fissures and splinters it in all directions. The French Le-Be bullet in every way resembles the Mauser and to a very great extent the first Lee-Netford used by the British army. It consists of a soft lead core inside of a nickel casing and theoretically the ball flattens or splashes on impact, but this it does not always do owing to its great velocity, which renders it more effective at long distances than at close quarters, as was proved by firing at an old donkey who was eating hay in a paddock. Three shots fired at him passed 'clean through him without at all disturbing him from his meal until the consequent peritonitis made him desist. In the Chitral expedition the Lee-Netford bullets could not stop the wild rushes of the tribesmen until the nose of the bullet was cut or rubbed off and the soft lead core made the striking point. In the latest Lee-Netford the soft lead nose projecting beyond the nickel jacket mushrooms out—on striking—and the less yielding metal behind becoming impacted so as to flatten or splash the ball a very cruel wound is made. The famous Dum Dum bullet which is a modification of the Lee-Netford and has a flat nose which does not project far out of its very thin nickel shield, collapses 'like a Concertina' making so ghastly a wound that it would be forbidden in European warfare. This expansive principle has been carried to its greatest extent in the "Webley's patent man stopping bullet" whose deep cup shaped nose acts like a wadding punch, cutting a clean circular hole which does not close up. Expansion commences at once and after travelling 6 inches into the body it produces a jagged hole 4 inches in diameter—quite sufficient to finish even a fanatic, but neither of these last two described bullets form conspicuous proportions of the armaments of Europe and the Dum-Dum bullet is still 'under trial.'

The character of the wound necessarily differs a little according to the bullet making it; but in the majority of instances the comparatively little damage done by rifle bullets is truly surprising. In most of the wounded men the ball had passed straight through the part struck, leaving a tiny bluish black hole at each end. Some of the edges of the entry wounds were *inverted* and the exit wounds had *everted* edges, but in the majority of the cases the wound of entry and that of exit seemed the same. So much so that even the patient could not (often) tell the one from the other. Some, especially the oblique wounds were round and gaping and the area of the internal wound more than often bore no proportion to that of the external one. In some cases the ball ripping through the tissues carries in pieces of cloth or other foreign bodies which are left in the bullet track to lead to suppuration, or to the formation of a troublesome sinus that needs continued tinkering.

* Abstract of a paper read before the West London Medical-Chirurgical Society.

The velocity, however, of the Lee-Metford and other modern bullets is so high that at close quarters pieces of cloth &c. are not carried before the bullet in its track and the severity of the wound as regards infective processes is thereby diminished, even though the extent of the deep injuries inflicted bear an out-of-the-way proportion to the small area of the external wound.

Bone injuries of the upper extremities heal much quicker than those of the lower. Heal and ankle injuries do badly. Unless it is 'keyhole' the fracture is nearly always comminuted and many of these fragments though denuded of periosteum do not necrose, but afford 'stages' for granulations to grow on and to ossify. Healing may occur without apparent inflammation; but should the latter set in the hard substances take on a passive, while the active inflammation is limited to the soft structures in the Haversian canals, which may become swollen and cedematous from exudation with the production of new bone. The heat produced by a bullet striking the bone adds to the severity of the injury which may result in osteitis, requiring continual surgical interference, or even in periostitis.

Joint injuries.—That a bullet wound of the knee-joint does not always suppurate, even though it may lame the patient for life, was proved by the Mayor of Lamia accidentally shooting a woman in her right knee, which the bullet perforated. She attended the Chalcis Hospital as an out-patient. The limb was placed in an improvised splint. There were not the slightest signs of suppuration, and after a few attendances she was almost well when she suddenly disappeared.

Injuries to soft parts vary considerably :—

(a). If a bullet strike a man obliquely a simple *contusion* may result, or there may also be a subcutaneous fracture.

(b). A ball may run parallel to the surface grooving it and making a *furrowed* wound, which is by no means uncommon.

(c). A ball fired obliquely burrows for some distance just under or a short distance beneath the skin and then emerges, making a *seton wound* which often results in a persistent and troublesome sinus, if not in death.

(d). Sometimes a ball enters tissues and falls out again. A soldier was shot in the left erector spinae. As there was only a wound of entry he was asked whether the field Surgeon had removed the ball. His reply "No" prompted a fruitless exploration. There were no signs of abdominal injury, so a second search was made for the bullet and in enlarging the wound to do the needful the poor fellow was put to so much pain that he asked what we were trying to do with him and on being told that we were trying to extract the bullet, he replied "I have it here in my shoes. I found it in my trousers after the battle."

(e). A bullet may perforate a part of the body and emerge almost unchanged, or it may itself be comminuted without necessarily fracturing a bone, which is really not so hard as is assumed.

Chest injuries are very troublesome. In the Greco-Turkish War a Martini bullet passed through the left shoulder—humerus uninjured—of an Evzone, into his lung where the X-rays shewed it inaccessibly lodged. Pneumonia, pleurisy, hæmorrhage into the pleura and empyema rapidly supervened. The chest was aspirated and a portion of rib excised, but the ball which could not be removed, afterwards became encapsuled. He became extremely ill and would have died but for excellent nursing by the Red Cross Sisters. In another case where a man was shot through the right chest the ball had smashed a rib and perforated pleura, lung and diaphragm, had also injured the liver. He survived his terrible injuries.

Pelvic and abdominal wounds are very serious and used to be a frequent cause of pyæmia. The mortality from them is rather high specially where the bowels or bladder have been perforated. Laparotomy has proved useful in some cases but the majority die from severe traumatism or from acute emphysematous gangrene.

A HINTER OF PRACTICE.

BRIEF NOTES OF THE TREATMENT OF THE NATIVES WOUNDED AT DARGAI.*

By Surgeon-Captain J. DAVIDSON, I. M. S.

Native Field Hospital (No. 55), Line of Communications, Tirah Expeditionary Force.

AFTER the fight at Dargai on October 18th, 1897, 14 wounded native soldiers were admitted into this field hospital—Sections B. C. and D. of No. 52 Native Field Hospital—and after the fight on October 20th, 52 cases of gunshot wound in native soldiers were admitted. Of the total 66 cases of gunshot wound, there were :—

1. Flesh wounds—of head and neck, 5; of trunk, 17; of upper extremity, 9; of lower extremity, 19.
2. Penetrating wounds of the abdomen, 2.
3. Wounds complicated by fracture of bones—of head, 1; of trunk, 1; of upper extremity, 5; of lower extremity, 7.

The only case that ended fatally were the 2 penetrating wounds of the abdomen, and 1 case in which six wounds were received, one of which caused a fracture of the bones of the left forearm. Secondary amputation was subsequently performed at the General Hospital, Rawal Pindi, but the patient died.

No operative procedures were found to be necessary beyond incisions for the extraction of bullets that had lodged, and one counter-opening for drainage. The bullets extracted were for the most part Snider, rocochets, and a few round bullets. The treatment adopted was to avoid as much as possible all probing or insertion of the finger into the wounds, to cleanse the wounds and the skin around them thoroughly by perchloride of mercury lotion, to dust the wounds with iodoform, and to cover them with boric lint wrung out of perchloride of mercury lotion and with antiseptic wool.

CASE I.—A Goorkha rifleman, admitted on October 18th, had received a wound about 1 inch in diameter in the centre of the forehead, about 7 inches from the roots of the hair. He did not seem to suffer any inconvenience from it. On examination by the finger, a small depression was found in the outer table of the skull and a fissured fracture extending from the depression could be detected by the nail. Next day slight bleeding from the nose occurred, but he afterwards recovered without a bad symptom so far that he was sent to the General Hospital at the base.

CASE II.—Another Goorkha was admitted the same evening with an entrance wound 3 inches above and in front of the right great trochanter, and an exit wound in the middle line over the centre of the sacrum. The small size of the wounds made it seem probable that the injury was due to a solid Lee-Metford bullet. The wound was not probed, nor was any drainage tube inserted, and under the simple antiseptic dressing described above both wounds had healed up completely within a fortnight without the formation of a drop of pus. A small knob of callus developed near the exit wound where the sacrum had been penetrated.

CASE III.—A Goorkha rifleman, wounded on October 20th and admitted on 21st, had received a fracture of

* Reproduced from the *British Medical Journal* by request.

the right thigh in the middle third. The wound of entrance was on the outer and anterior part of the middle of the thigh, and the exit wound was in the middle of the back of the thigh. No drainage tube was inserted and under the dressing described the wounds healed without the formation of pus. The splint used was a long wooden splint reaching from the axilla to beyond the sole of the foot; a perineal bandage was applied to prevent shortening. On the transfer of the patient to the base on 9th December, the femur had united with only three quarters of an inch of shortening.

CASE IV.—In another case of fracture of the right femur admitted on the same day, the wounds of entrance and of exit were on the outer and inner sides of the thigh respectively, 8 inches above the lower end of the femur. The limb was placed in a wire back-splint (with side and foot pieces) which reached from the middle of the thigh to beyond the heel, and had a slight bend at the knee; over this a long wooden straight splint reaching from the axilla to beyond the sole of the foot was applied, and extension was maintained by a perineal bandage. In the first day or two the knee-joint became greatly distended, the skin over it was dark in colour, and the patient suffered from fever. It was feared that suppuration had occurred, but only serum was found on puncture by a hypodermic syringe. The swelling of the knee subsided under evaporating lead lotion and the fever subsided with it. But a fortnight after admission a slight discharge of pus took place from the inner wound and a few minute fragments of bone came away. As this wound healed a similar slight discharge of pus occurred from the outer wound. No drainage tube was inserted. On transfer to the base on 9th December the femur had united, the inner wound had healed and only a small ulcer remained at the outer wound. There was, however, about 2 inches of shortening.

In addition to the 66 cases referred to above, a few other wounded men were sent to this hospital from other hospitals with the force. Of these the only case worthy of remark was the following:

CASE V.—A transport driver was hit on 18th October on the right great trochanter, the bullet passing through from front to back. He was a most restless patient, yet his wounds healed readily without the insertion of drainage tubes, and the bone healed under treatment by a long wooden side splint and a perineal bandage. On his transfer to the base on 9th December no shortening could be detected, which leads me to believe that the femur had not been completely broken across.

The successful result of the treatment of the majority of the wounds may be attributed to the following amongst other causes:—

These fights occurred at the beginning of the campaign, and, prior to the receipt of injury, the wounded men had not been debilitated by prolonged fatigue and exposure. The wounded were promptly treated on the field, and so contamination of the wounds was prevented. Owing to the excellent arrangement made on the line of communications, it was possible for these wounded men to remain in this field hospital in Shinawri, the nearest camp, until healing had advanced so far that they could be sent to the base

with little risk of healing being retarded. The wounds were received at the beginning of the cold weather, and were treated in a dry and healthy climate.

—O—

TWO CASES OF DIABETES FOLLOWED BY COMPLETE CURE.*

By PROFESSOR PIETRO LUPO, M.D.,

Professor of Surgery, Naples University of Medicine.

Two years ago a woman named PIROLO came to me with an enormous honeycomb-like growth, extending right across her back from below the scapula to the first lumbar vertebra. Following my usual procedure of making several incisions, I scraped the bottom and walls of the growth to remove the necrosed fragments and after free lavage with sublimate solution filled the cavity with iodoform.

Suspecting diabetes as the cause of the slow progress of repair, I examined the urine and finding a large percentage of sugar immediately prescribed vigorous dietary, on the tenth day of which the sugar entirely disappeared from the urine and to-day PIROLO is in perfect health.

In May last I was consulted by a man named PARDO for digestive disturbances of over a year's duration, malaise, fatigue, pain in the legs, bronchial catarrh, visual disturbances and frequent diuresis. He had grown as thin as a skeleton and as his urine contained large quantities of sugar he was placed on an exclusively meat diet. In 20 days the sugar disappeared, but as the other symptoms were not ameliorated, he resumed a mixed diet, giving preference to meat with the consequence that the sugar reappeared, the other symptoms were highly aggravated, gangrene set in of the skin of both tibial regions and he was bed-ridden.

Being persuaded that uric acid diathesis, diabetes, oxaluria, &c. are different phases of one single morbid entity, I gave PARDO no medicine whatever, but placed him on the special diet I had given PIROLO of nothing but vegetables and fruits of every sort, wine was absolutely forbidden, as having a tendency to alkalise the blood—with the result that the gangrene was arrested, and on the 18th day, PARDO was not only able to walk about unaided but also improved rapidly in nutrition, and sugar and albumen were completely absent from his urine. After 60 days of the vegetable diet his urine showed 60 to 70 crystals of oxalate of lime for each field under the microscope, which might have prompted the fear that the patient had changed his diabetic condition for an oxaluric one—i.e. gone from bad to worse—but so convinced was I of the benefit to be derived from a vegetable diet, that I advised him to continue it and was pleased to note that the oxalate of lime also disappeared from his urine after a time.

As the etiology of diabetes is multiple, decisive inferences can scarcely be drawn from these two cases only; but we can safely conclude that many diabetes can be cured on the vegetable diet, and I now have under my care a case who shows 100 crystals of oxalate of lime for each field under the microscope and is rapidly improving in condition.

**A CASE OF SNAKE-BITE TREATED WITH
"MATHIESON SNAKE-BITE SPECIFIC."**

By G. C. MATHIESON.

Kotri.

Barnoo, a Hindu, *et. 35 years*, was brought to hospital on 25th July 1907, at 7-30 A.M., said to have been bitten by a snake, about half an hour previously.

The patient, a pointaman, North-Western Railway, Kotri, stated that he put his hand into a basket to take out a pair of shoes, when he felt something sting him; he withdrew his hand and called out to his brother, who on searching the basket, found a snake which he destroyed. The patient is of fair constitution; appears to be in great agony.

Two distinct punctures could be seen on the dorsal surface of the third phalanx of ring finger of right hand; the hand is much swollen and very painful, complains of giddiness and nausea. Pulse small, 120; respiration, 36; Temperature normal.

The punctures were incised and a few drops of "Mathieson snake-bite specific" applied and continued every 3rd hour. Twenty drops of the same drug were given internally in half a wine glass of water, he was also made to inhale the drug from time to time.

At 12 noon, the pain and swelling increased considerably, site of an old fracture in left forearm became very painful and swollen. Blood exuded from the gums. Conjunctiva injected, singing in ears. Stools mixed with blood. Urine bloody. Temperature 101; pulse 130; respiration 40.

4 P. M. General pains all over the body. Blood oozing freely from mouth and nose.

10 P. M. About the same. The medicine to be taken every three hours during the night in 20 drop doses.

The hand and forearm of right side as also left forearm to be fomented with neem leaves.

26th.—Had a fair amount of sleep during the night, forearm is much swollen and very painful, still complains of the giddiness and nausea, jaundiced, pulse 120; respiration, 36; temperature 101. Blood still pouring from lips, gums, and nose, eyes still injected.

Twenty drops of the drug were given every fourth hour. Castor oil one ounce at once. Poultice of neem leaves and fomentation continued.

4 P. M. Four bloody stools during the day; pulse 80; respiration 26.

27th.—Had a fairly good night. Temperature 99; pulse 80; respiration 26. Small quantities of blood from gums and nose. Stools and urine still continue bloody.

28th.—Is much better, jaundice very marked, bleeding from mouth and nose less, stools and urine still show traces of blood. Temperature 100.

29th.—Much better, was ordered some quinine and iron. Patient steadily improved and was discharged on the 8th August.

Mr. MATHIESON is a retired Superintendent of the Sind Luni River Survey and now resides at Kotri, and will be glad to give any further information regarding his specific.

The snake was an *Echis Caranila* (Phoxena).

**THE ADVANCE OF MEDICINE IN INDIA AND THE
INDIAN MEDICAL SERVICE.**

UNDER the heading of "Bacteriological Laboratories and the Plague" the *Lancet* publishes the following apt and much needed remarks:—

"When the recent outbreak of plague occurred at Calcutta it was a matter of obvious importance that the exact nature of the disease should be determined with the least practicable delay. Happily for the Government of Bengal, the services of M. HARTKINS were available and he was able to report, as the result of a bacteriological examination, that the outbreak was due to true bubonic plague. We have heard a great deal about the establishment of bacteriological institutes or laboratories in India; now here was an occasion in which a bacteriological laboratory in Bengal would have been of the greatest use, and we are glad to notice that the *Englishman* of Calcutta has called attention to the subject. It cannot be said that among the number of medical officers of the Indian Medical Service there are not several who are both competent and willing to undertake this special work, and the sooner a properly equipped institution is established the better. There is probably no place in the world where bacteriological researches are more required to be employed in the investigation of disease-causes than in India, not only in the interest of scientific medicine, but as a matter of State policy. A really good staff of men with the requisite scientific training should be specially selected for the purpose of conducting these inquiries, and as they will probably find ample work in carrying on their investigations, these duties should be confined to them."

We have so frequently called attention to the backward state of modern scientific medicine in India, that it is now almost impossible to touch upon the subject, without feelings of irritation and indignation.

We have sadly retrogressed, we are overgrown with the emblems of antiquity and the anomaly of our position is made every day more glaring by the rapid advances that other countries have made.

It is no longer the custom for other nations to seek in British medical literature for information regarding the diseases of hot climates. We are now obliged to turn for the latest development, to the medical writings of Germany, France, America and Italy. *Ichabod! Ichabod!* our glory has departed, we have been out-distanced and are being rapidly left behind by nations which were much later in the field.

This is a scandalous state of affairs and it is not too much to say that it is a disgrace to the national honour of England, whose proud boast it is to lead the van of modern civilisation.

It was confidently expected that the terrible visitation of the plague and its awful ravages, would, even at the eleventh hour, have awakened the Govern-

ment, its leads to its shortcomings, and to the full appreciation of its responsibilities, and that in this way, out of much suffering and trouble, good would eventually have resulted.

It is late in the day now, these hopes have been unfulfilled, and it is with a sickening sense of disgust that we regard the future wherein we can see no trace of a re-awakening and no sign of any departure from the old lethargy we have grown accustomed to.

When some years ago the late Dr. ERNEST HART, the able and accomplished Editor of the *Journal* of the British Medical Association, spoke of this subject in Calcutta, there were many officers in the Indian Medical Service who resented his mild sarcasms; the unpleasant truths he uttered struck home, the dearth of good work in India was too notorious to be denied.

His words, however, might as well never have been uttered for all the good they did. We still proceed in the same listless fashion. If Dr HART chastised with whips, it has been forgotten, and others must come to scourge with scorpions before our lethargy can be dispelled, and a better state of things inaugurated.

In seeking for the causes which may be put forward to account for our sluggish state of stagnation, our want of all initiative, our inactivity and failure to keep abreast of the times, we recall the sad lesson from past history, that the British Government has never done anything for the advance of Medicine spontaneously. All our laws on the subject, and all our reforms, have been wrung from it by coercion. With every movement in these directions the name of some well-known man who has with energy and perseverance driven the bolt home can be associated. Foremost amongst these reformers stands WAKELEY, whose noble life has recently been epitomised in these columns.

There is unfortunately no powerful and independent public opinion in India, to drive our rulers to take steps which are apparently so repugnant to them. Above all no influential medical opinion.

What might not the Indian Medical Service have done with all its grand traditions? It is its opprobrium that it has done nothing. It is a service without coherence, without union, without influence, a combination of varied and isolated interests, where each man fights his own battle, too frequently a merely pecuniary one.

What a contrast is presented by the magnificent combination of the sister service, the Army Medical Staff, which has overcome the stubborn opposition of the War Office and wrung from it such magnificent reforms, not only to its own glory, but for the advantage of the profession at large.

It is the custom of the Indian Service to scoff at these agitations and then to willingly share in the profits, while for the very titles it bears, it is indebted to the sister service.

They will only have themselves to thank, if on the present occasion they are left out in the cold, as appears likely to be the case, and if the victory is barren of remnants for the jackal.

It is time the Indian Medical Service woke up to a full sense of its responsibilities, and learnt that the custom of turning the other cheek to the smiter, is not the way to general advancement in this world.

It is time it learned to manage its own affairs,

it has been in swaddling clothes long enough. What is there in the nature of its services that it should be under the thumb of the Civil Service? Why must the advancement of its members be subject to the good will of some Secretary to some Government or other?

A sad picture of the pitiable state of servility to which this fine service is reduced, is set forth in the story of the appointment of a senior officer to a much sought after station. He got the appointment because he understood the particular ailments of the Chief Secretary's family, and the Chief Secretary wanted a doctor upon whom he could depend, and who was supposed to understand children!

When a book on plague is published in India it is published by a member of the Civil Service, and another member of the same service teaches us in the Bengal Legislative Council what we do not know already about plague, the "Kisley-plague" we mean.

It is only too plain that the Indian Medical Service can never have any influence in the country until it becomes jealous of its own rights, and until it takes the Government of its own body into its own hands. In matters of public reform in the Medical profession the Office of the Director-General of the Indian Medical Service is compelled to admit that it is absolutely powerless for good.

As we are sorrowfully forced to the conclusion that there is no prospect of its doing this, we must look to other combinations and associations for the future rehabilitation of Indian Medicine.

—o:—

THE PRESENT POSITION OF THE THERAPY OF TRAUMATIC TETANUS.*

III.

LET us consider the foregoing case. We see that the wound was of such a description as to dispose to tetanus, and that nine days after it was received the first appearance of spasm was observed; it did not come on in the usual manner with trismus, but with a local spasm in the wounded limb.

Trismus first appeared on the 13th day. As the other tetanic symptoms did not develop very rapidly, this case falls into the category of the milder severe.

It is difficult to say, what effect the first serum injection had upon the further course of the disease, but as the temporary improvement during the first day was succeeded by a severe aggravation, we may infer that already a large dose of the poison had been absorbed into the system, by which the prognosis was rendered far from favorable.

The local treatment consisted in the thorough cleaning and disinfection of the wound, especially the wound of the elbow, the others were trifling. In employing in this disinfection our usual corrosive sublimate solution one in ten thousand, I was guilty of a sin of omission according to SAHLI, who considers the addition of hydrochloric acid, or tartaric acid necessary, or that some other disinfectant should be used.

Probably it would have been better if the wound in the elbow, which must be regarded as the local seat of infection, had been laid open and thoroughly destroyed, had this been done the disease might have been less protracted.

It is very likely that there was some injured tissue, or at any rate effusion of blood in the deeper part of the wound,

* By Von. Dr. A. Haddaun Heidelberg. Translated from *Munchener Medicinische Wochenschrift*.

the latter was proved to exist by the reaction made later on, but it is impossible to say that it was the seat of the infection for the cultivation made from it did not give positive results.

Later on, I ascertained by means of Röntgen-Rays that there was a contaminated fracture of the epicondyle int. hum. It is not improbable that the specific virus found in this condition a favorable breeding ground, probably the early appearance and the long continued stiffness of the arm may find its explanation in a severe local infection of this nature.

Whether the injective material was opened up, and evacuated by the incision, it is difficult to say.

What particular action had the serum? Immediately following the first injection there was no result, the first decided improvement occurred on the following morning. The evening was however, marked by an aggravation and this occurred regularly during the subsequent course of the sickness; this regular alternation we have not noticed in the cases that have hitherto been recorded.

In spite of the injection there was a continuation of the tetanic process and gradually other groups of muscles became involved. In order to combat these, narcotics were called in, and apparently with good effect, the patient as a rule got some rest after chloral and opium.

Then suddenly there was a rapid and increasing aggravation, such as might follow a second, acuter, injection.

The re-action which followed upon the second injection cannot surely be attributed to accident, the contrast is too strong for that, and in the whole of the literature of the subject there is no case where tetanus has undergone such a sudden transformation under any other treatment.

Especially remarkable was the sudden lessening of the frequency of the paroxysms to every half hour, the diminution of the trismus after a few hours, and the spontaneous opening of the mouth to 1.5 cm. on the following morning, while up to then it had been firmly closed.

The spasm of the tense and hard muscles of the body also disappeared more rapidly than occurs under other methods of treatment.

The further progress to recovery then again became more gradual, and was always of the same type, marked by slight morning remissions and evening exacerbations, the stiffness in the wounded arm persisted a particularly long time. When the patient presented himself again at Christmas it had not entirely disappeared and was specially marked in the deltoid muscle.

We consider that we are justified in pointing to the foregoing case as an illustration of the favorable effects of the tetanus antitoxin, it is clear however, that we cannot rely upon it alone, without the assistance of the other remedies mentioned. We hope, however, that those, who like Ross, are sceptical of the antitoxic serum treatment will acknowledge its favorable action in this case.

While this patient lay seriously ill, in conformity with the law by which cases run in pairs, a second case came under our treatment of the variety known as head tetanus, on account of the participation of the nerves of the head. PAUL BARIAN, 45 years old, a cement worker from Lemmen, met with an accident on the 8th November 1897, at the stone quarry near Lemmen, while he had loaded and was firing two blasting charges.

One went off, the other hung fire, when as went vider, and was in the very act of removing the fuse, it suddenly lit up and the blast exploded in his face.

The surgeon who was called in put on a dressing and sent the case as quickly as possible to the clinic.

Present condition.—A very strongly built man, with the whole of his face disfigured with wounds in which are embedded particles of stone and gunpowder, the left side of the face is the most injured. The left eyeball is totally destroyed, there is a wound in the cornea out of which protrudes the iris, the ciliary body and the lens. Beneath the left side of the lower jaw there is a large and gaping lacerated wound of the skin, at the bottom of which, the lower edge of the jaw bone is exposed to the extent of 5 cm., there is no fracture.

The bottom of the wound is much bruised and it is surrounded with discolored ragged tissue. There is a second smaller and shallower ragged wound on the left side of the neck.

The nose is split down the middle and the septum smashed.

The whole face and especially the right cheek and eyelid is much bruised and sprinkled with particles of stone, the underlip is much swollen and has several wounds, on the left upper arm and breast there are superficial abrasions.

Clinical diagnosis.—Multiple bruises and wounds of the face, &c., with foreign bodies impacted. After cleaning the wounds and the face as well as possible a wet dressing was applied.

9th November.—On the advice of the eye specialist who was consulted, the patient was anaesthetized and after the removal of the conjunctiva the sclerotic was cut round and the whole contents of the collapsed eyeball removed with a sharp spoon. So that only the bare sclerotic remained as a black ground.

13th November.—Up to this date the case progressed favorably, the wounds commenced healing and the swelling about the right eye went down so that the patient could again open it, this morning, however, 4½ days after the accident trismus appeared, he could only drink with difficulty and by holding apart the teeth with a spoon. The finger introduced into the buccal cavity felt the masseter hard and tense. On being questioned the patient said that he first noticed the spasm about 12 o'clock the previous night. It has, however, become so marked already that the breathing is difficult and the muscles of the face appear to be affected. The patient holds the spoon firmly as a wedge in order to keep the lips and teeth sufficiently open, since the nose is stopped up in consequence of the wound, and of the scabs that have formed.

No stiffness of the neck or of other groups of muscles. Temperature 98.0°F. At 10 A.M. 5 ccm. of BEHRING'S serum as mentioned above dissolved in 30 ccm. of water was injected into the left median vein.

During the course of the day the trismus was apparently unaltered, the patient as before can only get his breath, by himself holding the spoon jammed between the teeth so as to hold the lips and teeth open. Up to this evening no increase of the tetanic spasm was observed.

14th November.—The wound on scrotum pus freely, cultivation of which with agar was negative.

There is a decided increase in the difficulty of breathing, and in the trismus, at the time of the morning visit he could of his own accord open his mouth to the extent of 1 mm., nevertheless he has still to keep the lips separated with the spoon; in order to make breathing through the nose easier, a sufficiently large drainage tube about 3 to 4 cm. long was introduced into each of the shattered and swollen nostrils. The masseters can still be felt from the mouth in firm contraction.

The patient complains of great dryness in the throat, which to a certain extent is relieved by means of plenty of fluids administered at intervals by means of a cup with rubber tube attached, the temperature in the afternoon reached 102.3°F.

14th November.—Slight pains in the neck, turning movements perfectly free, flexion limited, the muscles of the neck feel harder than before, trismus which had improved is also worse.

16th November.—When he was being dressed it was noticed that the right angle of the mouth hung down powerless and it was discovered that there was complete right sided facial paralysis, pressure over the point of exit of the facial nerve caused pain and increased the trismus, the spasmodic contractions of this side of the face are not relieved, the left facial nerve is unaffected.

Towards midday the difficulty of breathing became aggravated and there were passing spasms of respiration. The flexor muscles of the head are strongly contracted on both sides, the head is fixed in a flexed position and the other muscles of the neck and throat are in a condition of tetanic spasm. The paroxysm only lasts a short time, still after it has passed the muscles mentioned can be felt like tense cords. On account of the danger of suffocation, preparations were made for tracheotomy, and in the evening an enema of chloral and 20 drops of opium were given.

17th November.—This morning he feels well, the trismus is less and the difficulty of breathing and swallowing not so great.

As the wounds are still in some places covered with a thick coating the result of a previous dusting with iodo, a thorough cleaning of them from all extraneous matter was undertaken to-day. This showed that beneath their coating a quantity of pus was concealed.

All the wounds were, as far as could be conveniently done, enlarged with a probe pointed knife, and thoroughly cleaned with a 1 per 1,000 solution of corrosive sublimate. This procedure apparently exhausted the patient very much, so that after it, there was a return of very severe trismus and difficulty in swallowing, chloral was repeated in the evening.

18th November.—Condition easier. In the course of the afternoon there was an important aggravation of the spasms of the muscles of deglutition and of respiration. At every attempt to swallow spasms came on and threatening suffocation. The temperature reached 103.7°F. In the evening swallowing was altogether impossible and the patient complained of hunger. Nutritive enemata were given. A small stone was removed from the wound in the cheek.

The threatening condition appears to be an indication for an other injection of antitoxin. On this

occasion 10 ccs. of diphtheria antitoxin was injected in four different places in the neck, and also into the manner adopted by EISELMANN and WUNDERLICH.

19th November.—Had a great relief at the evening visit the trismus was appreciably less, and the patient is again able to swallow without suffering much, subjectively he finds himself better. Nutritive enemata still continued. Exanthem of neck and throat at the points of injection!

The wounds are healthy granulating well in places. Facial paralysis unaltered, less secretion from the wounds of the neck and lips.

20th November.—Difficulty in swallowing almost entirely gone, trismus so slight that the patient of his own accord can open his mouth 1 cm. wide, breathing quite free, the necessary nourishment is swallowed. Nutritive enemata stopped. Temperature normal.

22nd November.—Continued improvement in the trismus. Now and then when swallowing a sudden increase of trismus and of spasm of the muscles of deglutition comes on.

23rd November.—These spasms occur to-day regularly and quite suddenly while swallowing, immediately after a small quantity is swallowed, further swallowing then becomes impossible and the breathing is so obstructed that slight cyanosis appears. Nutritive enemata have again to be employed.

24th November.—To relieve constipation aperients were given, after which copious stools came away. Swallowing still difficult. Now and then the patient has an attack of coughing, and the expectoration is very difficult on account of the spasms of the muscles of deglutition.

25th November.—Difficulty in swallowing less. Expectoration still subject to spasms. Continued improvement, trismus becomes less daily.

2nd December.—Patient can now swallow without difficulty and is able to take solid food. Facial paralysis still unchanged.

8th December.—To-day he can again draw up the angle of the mouth and can close his eye better.

15th December.—No pain now in the neighbourhood of the facial nerve, but on the other hand when the sensibility was tested it was found that there was no sensation in the skin of the cheek.

20th December.—Trismus still perceptible, the wounds of the face are healed except the large granulating place over the left side of the lower jaw.

22nd December.—The point of the nose which was split was to-day stitched up, after the edges were refreshed, under cocaine anaesthesia.

The further progress was uneventful. In the beginning of January a false eye was introduced, which to a certain extent follows the movements of the other eye.

Finally the wound of the under jaw healed by granulation without any exfoliation of the bone that was exposed. He was discharged on the 24th January 1898.

We must close the foregoing case of head tetanus amongst the most severe. Already four days after the injury trismus appeared, how far the muscles of the face participated in it at the beginning it is not safe to say, for the wound at the face was so horrible and disfiguring that a sufficiently careful investigation

the rapid onset of the symptoms of the triismus, that in the case could only be caused locally; the swelling of the lip however makes it difficult to be certain on this point. The facial paralysis which appeared after a few days is according to BRUNNER a direct proof of the severity of the infection and intoxication. The fact is that paralysis of the muscles of expression is always the result of a very severe local poisoning. According to the experimental researches of BRUNNER an isolated facial paralysis never results from a blood injection, but only from a concentrated local action.

Much depends upon the affection of the facial nerve concurrently with spasm of the motor Trigeminal. Triismus, etc., which was the primary lesion; facial paralysis or triismus? this cannot be decided with certainty. Whether in this case there was also paralysis of the muscles of the eye, which is prone to follow wounds in the neighbourhood of the eye, like the wound of the upper lid of the right eye which existed here, is difficult to decide, since the severity of the injury and the multiple wounds of the face rendered such an investigation difficult, and on account of the loss of the left eye a comparison with it was impossible. We think we are safe in pointing to the deep wound in the middle of the right cheek as the place from which the infection spread.

From this wound a small stone was expelled after several days, and I regret that this foreign body was not made use of for an inoculation experiment as cases are known in the literature of splinters of wood having been employed in this way, perhaps it would have led to safer conclusions. That the wound of the nose was not the seat of infection follows from BRUNNER's observations, for he shows that a wound in the median line leads to a double sided paralysis.

Such a severe infection with paralysis is according to Brunner only observed in the region of the nerves of the head and especially of the facial nerve. Moreover the facial appears to be an easily affected nerve, for in other injuries of a less severe kind it is connected with paralytic changes.

Further the rapid onset of the spasm of the muscles of deglutition and of the glottis is characteristic of head tetanus and of the severity of the case. In this case they were connected with reflex excitability of a high degree, so that when a drink was taken the effect of a few drops was sufficient to bring on spasm of the muscles of deglutition and to render further swallowing impossible. It was therefore necessary to support the patient's strength with nutritive enemata.

Now what effect had the injection of tetanus anti toxin in the second case. We have seen that it was injected not quite 12 hours after the onset of the symptoms, in the median vein; the condition was at first unchanged, considering the severity of the case this itself must be looked upon as a favourable result, but its favourable effect appeared certain on the following morning when the triismus began to disappear, and the patient could again open his mouth to the distance of 1 cm. The difficulty in breathing also diminished, but no further effect was noticed.

The progress of improvement was however important; and especially the lessening of the triismus which has been observed by others to follow as a consequence of serum injection. As triismus is the first alarming symptom to appear, as also does it appear to be the first to be affected by the treatment.

But although the improvement in the triismus was maintained, on the next day a further development of the disease took place, the neck felt stiff though on movement there was no spasm. The next day there was contraction of the flexor muscles of the head, difficulty of breathing with passing spasm of the glottis. Narcotics gave relief.

On the next day mechanical irritation produced an aggravation in which the triismus participated, this increased on the following day to an alarming degree accompanied by severe spasms of the muscles of deglutition and of the glottis. Accordingly antitoxin was again injected, this time into the affected muscles.

The consequence was again, a marked improvement in the triismus, and in the act of deglutition, the reflex excitability was undoubtedly diminished.

From this time there was continued improvement, interrupted now and again by spasms of the muscles of deglutition. Finally the facial paralysis disappeared, it was not affected in any way by the injection.

Considering the objective signs, I think it is impossible to deny that in this case also the serum treatment had an undoubted good effect. The severity of the disease and the very unfavorable prognosis are almost a direct proof that it was the early injection of antitoxin which preserved the patient's life.

Following these two cases there came a third on the 4th February 1898, curiously enough from the same place as the first and sent in by the same physician.

KARL B, 28 years old an agriculturist of Waihestadt received on the 29th January 1898, a small wound on the lower lip from the thong of a whip, which he was cracking. The lip swelled up and the physician washed the swelling the next day with corrosive sublimate, on account of its trifling nature, he did not apply a bandage. The next day the swelling went down and the wound apparently healed, when suddenly on the 3rd February, after five days, when eating his mid-day meal he found a difficulty in chewing. He could not open his mouth as freely as before and by the evening he was unable to separate his teeth. Two days before his father had remarked that his right eye appeared smaller than the left. The physician who was treating him immediately sent him to the clinic.

Present condition.—4th February. A somewhat pale but well nourished man, internal organs sound, urine normal. On the lower lip 1 cm below the right angle of the mouth there is a scab of the size of a millet seed. The surrounding tissue is much swollen the tissues appear infiltrated and there is some pain on pressure, no redness, no fluctuation. On the right side there is slight ptosis of the upper lid, obliteration of the naso-labial furrow, on the other hand the wrinkles of the right side of the forehead are accentuated. The

eye can be completely closed, and offers hardly less resistance to passive opening than the left.

Movements of the eye muscles unaffected. The *Masseter* feels stiff and from the inside of the mouth the anterior edge can be distinguished as a hard ridge, the right is more marked than the left. The cheeks on the whole are slack.

The teeth are firmly clenched the upper ones overriding the lower, with the strongest effort they cannot be separated. The tongue can be freely moved in the mouth, no difficulty of breathing or of swallowing. Fluid nourishment can be taken without much difficulty as it is sucked in between the teeth.

In the neck there is a perceptible hardness of the clavicular portion of the right sterno cleido mastoid, and the insertion into the mastoid process is also thickened and hard. No other groups of muscles are affected, there is no spasm of the neck and the head can be moved freely.

Diagnosis. Head tetanus, with partial facial paralysis following wound of the lower lip.

After the patient was bathed and put to bed. Under chloroform, an elliptical incision was made round the wound and the enclosed tissue down to the submucosa of the lip removed; the wound was then thoroughly disinfected with a 5 per cent. solution of carbolic acid, and swabbed with damp Orthokresol gauze (1 p.c.); at both ends silk worm stitches were introduced, and plaster put on. The anæsthetic gave no trouble and under it there was no diminution of the contraction of the frontal muscles, or of the trismus.

The excised portion of skin on section through the centre shows what appears to be the prolongation of a hair-bulb or of a sweat gland, a fibrinous wedge shaped plug which extends into the sub-connective tissue and there spreads out. This portion is not closed at the bottom and it appears as if the whole of the affected tissue has not been removed. The excised portion was divided into four parts which were placed under the skin of the back of two rabbits, one guinea pig and one mouse respectively.

During the night the patient complained of difficulty of breathing, spasms not marked.

5th February.—At morning visit it was observed that the wrinkles on the right side of the face were very strongly marked, on this account the whole face presents the appearance of risus Sardonius. If the patient tries to drink he cannot suck in the fluid on account of spasm of the lips, and the effort brings on reflex spasm of the glottis with cyanosis of the face.

The movements of the head are no longer free, bending forward is specially limited, there is obvious spasm of the neck muscles, the flexors of the head are very tense and hard; now and then there is slight opisthotonos. It is difficult to raise him up.

The patient is for the future to have nutritive enemata (three times a day, two eggs, beef-tea, wine water) also an enema of chloral.

The wound was dressed and the stitches removed, for the thorough disinfection of the wound it was carefully

cleaned out with tincture of iodine (SANTAL) and dressed with damp Orthokresol gauze.

At evening visit, frequently recurring spasms were observed for the first time, coming on every few seconds. On being questioned the patient said he had first noticed them about half an hour before, that is about half past four o'clock. They are not accompanied by pain. The breathing is not embarrassed, and he says the tongue can be moved fairly well in the mouth. The trismus is however, so pronounced that his speech is no longer intelligible. The extremities are unaffected, likewise the pectorals. On the other hand the muscles of the abdomen are tense.

The spasms referred to chiefly show themselves in opisthotonos with the head drawn back and boring into the pillow, accompanied by strong contraction and distortion of the muscles of the face. Spasm of the neck is very pronounced. The right upper eyelid can no longer be as completely closed as the left one. There is constant profuse perspiration of the face and especially of the forehead.

The antitoxin that was telegraphed for arrived in the evening, this time in solution, a single dose of two small flasks (each 25 cc m—500 J,—E) this was immediately at 8 P.M. injected into the left median vein. Morphia was also injected somewhat later.

Immediately after the injection there was no reaction, in the following hours the temperature rose and at midnight reached 103.6°F. The rapidity of the pulse was much increased, 155 to the minute, but strong and regular. During the night the number of the spasms was unchanged, they are very frequent from 3-4 every five minutes, it often happens that a very severe one succeeds a mild one.

The patient on the whole presents a very grave appearance. The mouth is dry, and a dry secretion collects upon the teeth, the face is covered by profuse perspiration, a colossal perspiration burst forth from the whole body.

The phlegm which collects in the mouth can only be expectorated with great difficulty between the teeth. Any attempt to drink brings on at once repeated swallowing movements, then spasm of the muscles of deglutition and of the glottis sets in and makes further drinking impossible.

He can no longer suck as he has lost control over the movements of the lips; when drinking he lets the water run into the left buccal cavity, then directs it into the gullet by throwing his head backwards.

In the course of the night the temperature fell again to 99.5°F

(To be concluded.)

PLAGUE IN CALCUTTA. THE WRONG CHILD!

While people in Calcutta, like a man recovering consciousness after some violent catastrophe, are beginning to look about them in a half bewildered way, and to ask themselves in a spirit of incredulous surprise what has become of the wonderful plague which was burst upon them like a bomb some three months ago, we would like very much to know how the official sponsors view the behaviour of the strange bantling, on which they were so eager to confer the redoubtable cognomen of Plague and exhibit in the face of the whole world.

Its behaviour has been so eccentric, and so utterly unlike what was confidently expected and prophesied by its god-parents, that many are raising the question in all seriousness, if it is not possible that the christening ceremony was undertaken for the wrong child.

When the new arrival was first announced, a perfect reign of terror seized the unhappy city in its implacable grip: no evil portent could have wrought greater havoc. Labour ceased, trade stood still, the streets were encumbered with refuse, which there were none to remove, while the people in a state of the wildest panic, rushed blindly forth in hundreds of thousands, flying from a plague stricken city, to seek safety at the furthest point they could reach.

The imagination of an excitable populace was raised to the highest pitch, one scare followed another, and behind every whisper seemed to lurk the most dire plots, and the awful shadow of death.

Bombay sent us kindly messages of condolence and warning beneath the thin veil of which we could read a sort of placid satisfaction that the enemy it had so long and vainly fought against, was about to bestow its unwelcome attentions elsewhere. Verily there is something in the misfortunes of our dearest friends which nature has enabled us to bear with ease and equanimity.

All this dark shadow has now passed away, the terror stricken have returned, the streets are once more crowded, and the noise and bustle of busy trade have once more resumed their wonted course. The plague was kind enough to regard the Sabbath as consecrated and so for five consecutive Sundays no plague cases were reported.

How has this miracle been wrought, how has this wonderful transformation been brought about! Has the government repealed its decision, and has the stigma of being plague stricken been removed? No, this has not been done; on this point the same doubt and uncertainty exists as before; but the people have courage, they have surveyed the situation for themselves and the quiet condition of Calcutta at present is due to the conclusions they have formed.

When it was noticed, after the first announcement of plague that the disease was not spreading very rapidly, we were told that this was always the case, that at first it was always sporadic, that it was incubating, and quietly gathering strength for the final spring which was to destroy us.

When this deadly spring was still further delayed, we were told that the weather was unpropitious, the weather conditions which were favourable or the reverse to the development of plague, were confidently discussed

and laid down from the short experiences of Hongkong and Bombay, and we were warned to wait till the rains broke, then the excessive moisture and diminished sunshine would wake the epidemic into life.

The prophetic day has however come and gone, and yet we are still in the same state as before, if anything now that the monsoon is in full flood and the soil of the city is water logged, we have had no "plague" cases during the past past five days. The evil predictions have once more been unfulfilled. So we are now told to wait for an awful outburst the next cold weather.

This we are quite prepared to do, in the confident expectation that this evil prediction will prove as false and groundless as its predecessors.

In the meantime the Government stoutly, and as it appears to many, obstinately adheres to its first pronouncement; according to its declaration the City of Calcutta is infected with true Plague.

In view of the immense importance of this matter to all the best interests of the City, it is difficult to believe, nay more, it is altogether incredible that further researches on the subject have not been made; we should like to think that a continuous series of bacteriological investigations have from the beginning been undertaken, and are still being carried out; it would reassure many to know that this very essential action was being taken, but we have no information on the subject.

Is it possible that no further reliable bacteriological investigation into the so-called cases of plague in Calcutta has been undertaken since the disease was pronounced to be true epidemic plague on the 30th April last, on the strength of Mons. HAFKINE'S statement that he had found the plague bacillus in some specimens which were submitted to him anterior to that date?

If such investigations have been carried out we are in ignorance of the fact, for nothing of the kind has been published; if they have NOT been carried out there is grave cause for censure in some quarters, such a dereliction, such a confessed failure to understand the overwhelming importance of the case, thrusts it as a paramount duty upon the Corporation of Calcutta to take up the strongest position and press the matter to the utmost; and this duty it owes to every citizen in this immense capital.

The government has been asked to provide an expert bacteriologist, it either cannot or will not; such an *impasse* cannot be supported much longer. It is high time that the Corporation should take action in the matter and provide one for itself.

The distribution of the so-called plague cases in Calcutta is worthy of close attention; that the disease should be limited at its onset to one quarter and that every endeavour should be made to prevent its spreading beyond these limits, is what many people would naturally expect from a malady of the nature of plague, which is above all things supposed to be an imported disease.

Far from this being the case, it appears to be everywhere, the evenness of its spread North, South, East and West, is little short of amazing. So much so that if one or two wards be excepted, it is difficult to say that one portion of the city is affected more than another, and in not a single ward has the disease assumed an epidemic form.

These facts argue strongly against an imported disease. They are on the other hand very strong evidence in favour of the disease being of an endemic nature, perhaps accentuated in severity by some conditions which do not always prevail, or by cyclical causes.

This position we have taken up from the beginning and we are very far from seeing any cause to alter it now.

It is a curious phenomena, we can call it nothing else, that there are to be found persons ready to attribute the non-spread of the plague to the energetic measures that have been adopted for its restraint, and to the vigorous way in which it has been tackled; we cannot see any grounds for such an assumption. Had it been demonstrated that the disease was imported into one definite locality, had it become epidemic there and spread rapidly, and finally had it been hemmed in and prevented from extending itself to neighbouring places, there might be some reason in such a contention, but it is a fact that these conditions have not been fulfilled in a single particular.

There is no definite evidence of importation, instead of their being one focus, there are hundreds of foci of disease and new ones are constantly appearing. While in not a single focus has the disease taken on a really epidemic action.

Are we to believe that the Calcutta measures are so much more successful than those of Bombay, or that the Calcutta disinfectants are so much more effective, that each of their foci is effectually dealt with and destroyed instantaneously? He who has faith to believe that this is the case, should not want for much in the world, for of a truth he could move mountains!

But even were such the case, how are we to account for the continual uprising of other foci of infection?

The endemic theory appears to be the only theory capable of throwing any light on the subject.

We have read that Mr. DRYAN the Sanitary Commissioner, has said that it is all "bunkum" to deny that the cases, occurring in Calcutta are true plague, but in this new fangled style of official language, we do not impose much confidence; for in the first place we do not know that the Sanitary Commissioner is to be looked upon as an oracle, and in the second we believe that had he anything of weight or importance to say on the subject, he would have refrained from talking about "bunkum."

Plague or no plague, and putting all theories aside, there is one consoling reflection in which we in Calcutta can safely and complacently indulge. That is the unpre-
cedented healthiness of the city, we are so accustomed to read day after day that our present death rate is below the average for five years, that a decrease of even twelve, per 1,000 does not astonish us. It is somewhat of an anomaly that a visitation of "true epidemic plague" should diminish the death rate, but we are reconciled to it, and we think that in this respect Calcutta may be proud of having made a record.

In spite of our evil sanitary condition, which has of late been if possible worse than before, the plague does not spread; and we view the gradual dwindling of other diseases, almost to the vanishing point, with satisfaction. There is no reason to be alarmed about our health, it continues good, so good in fact that there is absolutely nothing in Calcutta to attract the attention of foreign plague commissions, still we wish that some of these gentlemen would visit us, and tell us a little more about ourselves than we can learn from a parental government or its medical protégés.

COMMENTS AND NEWS.

SIR RICHARD THORNE THORNE ON ENTERIC FEVER.

In the Annual Report of the Medical Officer of the Local Government Board for 1896-97, Sir RICHARD THORNE THORNE says with reference to Dr. BULSTON's report on Chichester.

"It goes to show that enteric fever, though mainly distributed in epidemic form by means of water or milk, is by no means always a 'water-borne' disease; and it raises anew the question as to how far recurring prevalences of enteric fever in one town or spot, can be due to the persistence in more or less active form, in certain soils of the organism of that disease. This question has, for some time past, been deemed in the Medical Department to be one deserving of more careful study than had hitherto been bestowed upon it..." Dr SIDNEY MARTIN was therefore instructed to make experiments on the behaviour of the typhoid bacillus in different soils, and his report is appended. He further says.—

"Dr. MARTIN's testing of the question submitted to him has not yet advanced beyond a preliminary stage, but already he has ascertained that the behaviour of this microbe is very different, when, in the absence of competing micro-organisms, it is implanted in organically polluted soil, and in soil from an altogether uninhabited and uncultivated area. In soil of the former sort, as, for instance, in samples of each from Chichester, the typhoid bacillus speedily increased and spread abroad, whereas in the virgin soil under like conditions of temperature and moisture, it languished and quickly died out. Dr. MARTIN's researches in this connexion are still proceeding."

"In 'milk epidemics,' whether of enteric fever, scarlatina, or diphtheria, indication has now and again been forthcoming that infection of the disease current in a particular outbreak has, subsequent to gaining access to milk, multiplied therein before and after delivery of such milk to customers of the implicated dairy. Nothing is however, with certainty known of the conditions which favour, or which are antagonistic to, multiplication in milk of one and another infection, though it has been surmised that certain of the numerous bacteria apt to be present normally in milk may have an important influence on the life processes of disease microbes that happen to obtain access to that fluid. With a view, therefore, to procuring knowledge on this subject, Dr. CAUTLEY was instructed to ascertain which of the bacteria ordinarily to be found, or abnormally present, in milk, tend to render that medium a multiplying ground for the typhoid bacillus. Dr. CAUTLEY has not been so fortunate as to obtain, among the numerous samples of every-day milk with which he experimented during several successive months, any one sample in which the typhoid bacillus conspicuously multiplied; so that thus far his primary object was not attained. Nevertheless he has ascertained that this bacillus can persist, though diminishing rapidly in number, many days in milk under the conditions in which it is delivered to and retained in households, and that it can be recovered in viable condition even though 'the kept' milk has turned sour. Incidentally he found that the micro-organisms commonly present in milk, though always extremely numerous, varied in abundance with the season of the year; and that in winter, when they were least abundant, the typhoid bacillus, after addition to milk, survived longest. Acting on this suggestion, he ascertained that in sterile milk, in the absence, that is, of a plurality of different competing micro-organisms, the

typhoid bacillus not only persisted, but even multiplied considerably. In sterile milk, in association with only a single competitor—as, for instance, bacillus lactis, citrium lactis, or yeast—the typhoid bacillus was little hindered in its life processes. But none of these micro-organisms was found to actually facilitate its multiplication in that medium."

In another part of his report Sir RICHARD asks—

"What are the local conditions by reason of which certain areas, whether registration counties, towns or villages, have, for at least a generation, become identified with such persistence or periodic recrudescence of enteric fever, as has continued to secure for them death-rates from that disease in excess of other districts, with some at least of which they may not unfairly be compared? Already there are indications which serve to show that whilst much of the diminution in enteric fever has gone hand-in-hand with the abandonment of water services, which being subject to receive specific pollution, served for wide diffusions and sudden outbreaks of enteric fever,—much of the persistent prevalence of that disease is associated with those systems for the disposal of excreta and refuse which still find favour in certain parts of this country, and which inevitably involve organic pollution of the soil. But the subject calls for much more study, both in its practical and scientific aspects, and this the more so since diminution, for the country as a whole in the death-rate of this typically preventable disease would seem to be coming to a standstill."

SIDE LIGHTS ON THE MALDSTONE TYPHOID EPIDEMIC.

MR. R. HARRIS REEVES, C.E., has published an interesting paper entitled "Report on the Maldstone Typhoid Epidemic from the Sewer Gas Point of View" in the *Public Health Engineer*. This paper is of interest both on account of the facts it brings forward and because it throws a side light upon the way in which epidemic disease is investigated in England. We have already shown that there is a considerable conflict of opinion between the authorities who devoted their attention particularly to the water supply (*Indian Medical Record*, 1st May 1898). Mr REEVES views the outbreak from a different stand point.

"It appears," he says "from the reports of the proceedings at the late inquiry at Maldstone into the cause of the epidemic of typhoid, that no evidence was produced showing the true sanitary condition of the town sewers in spite of what has been already written, and the opinions expressed by experts and others. The facts are these—A town of 82,000 inhabitants, unquestionably healthy, its death-rate low, with typhoid fever, although never quite absent, yet never previously epidemic, is in the space of three months devastated by a preventable disease affecting 1,908 persons, from which 132 deaths occurred, causing a loss to the town estimated at a 2½d. rate for a period of 20 years. Shortly after the outbreak the Medical Officer fixed on the water supply as being the cause; the water company were blamed right and left by the inhabitants, and at this point all scientific investigation appears to have ceased. On 29th September, the suspected water was cut off, and from that date, although the epidemic continued, no further steps were taken to discover infection from other sources. The prevalent opinion was expressed in a decided manner by Dr. ADAMS in his cross-examination, when asked whether, assuming the water to be all right, the state of the drains would not be sufficient to account for the outbreak of fever, and he replied "Certainly not."

But, previous to the outbreak of the epidemic of typhoid, diarrhoea was prevalent, and to any that diarrhoea accom-

panied by typhoid fever is not a result of sewer gas poisoning is contrary to previous known facts and experience. Cases have occurred in buildings where the sewers were supposed to be perfect from a sanitary point of view; yet on investigation it was found that the outbreak was entirely due to sewer gas. He then describes an outbreak which he helped to investigate where 60 cases of diarrhoea and 6 cases of Typhoid were notified. "The fact of sewer gas," he says, "being the cause of this typhoid epidemic was then not even questioned, the evidence being considered conclusive." He continues—It is a very open question whether there were not in the sewers of Maldstone, previous to the 29th September, gases which would produce typhoid in the same manner. To prove whether or not such was the case no examination appears to have been made, nor was an analysis of the sewage or the gases in the sewer made. Therefore, the question to be considered is, were there not in the sewers of Maldstone, previous to the 29th September, gases which would produce typhoid in the same manner as in the instance cited? We can only inquire into what would naturally take place in sewers under similar atmospheric conditions as those of last year. Unusual atmospheric and meteorological conditions are required to store up and disperse gases which would give typhoid. These meteorological conditions occurred in Maldstone last year, but not in previous years.

Town sewage similar to that of Maldstone gives off in transit 1 to 1½ cubic inches of gas per gallon per hour, these gases being produced by putrefactory organisms breeding in the sewage. The analysis of these gases shows their composition to be—carburetted hydrogen, carbonic acid, nitrogen, sulphuretted hydrogen, with ammonia and sulphate of ammonia, and a putrid organic vapour, sulphuretted hydrogen, composing only about 8 per cent.

In theory these gases are supposed to be destroyed by diffusion on mixing with the atmosphere at openings made for ventilation, but in most cases, during the months of May to September, it is only the lighter gases which escape, leaving the heavier ones in the sewers and in branch drains, to be discharged by excessive rainfall, or when the atmosphere on the surface, either by increased weight or by wind pressure, has attained sufficient force as a motive power to remove them. There is not the slightest doubt in my mind that sulphuretted hydrogen, produced from sewage organisms, whilst only forming 8 per cent. of the volume of gases produced, is the most active agent in undermining the health of a district. During the months from May to September, persons passing open gratings in the streets, on noticing the effluvia given off from ventilating shafts, would notice gases of a bad odour issuing from them and form the conclusion that good ventilation was going on instead of which it was only the lighter gases which were being dispersed, leaving the heavier ones in the sewers.

It is a very unusual occurrence for atmospheric conditions to allow these gases to increase in volume to such a large extent as they did between May and September last. Usually they are dispersed by rainfalls accompanied by gales of wind, which render them harmless. On the 29th September, the amount of organic sulphuretted hydrogen was not less than 16,720 cubic feet in the sewers of Maldstone, and the volume of fresh air polluted would therefore be 128,851,851 cubic yards, or an atmosphere equalling 1,779 acres, 2 yards, 6 feet in height, such atmosphere being recharged by the sulphuretted hydrogen 10 times before it was exhausted. But this equal distribution of sulphuretted hydrogen did not occur; the excessive rainfall of September 29, amounting to 11·94 inches in one day, sifted down and forced up into and about buildings sulphuretted hydrogen not so extensively diluted by the atmosphere.

"SEWER GAS AND ITS INFLUENCE UPON HEALTH"

We quote the following from the review of M. ROCHLING's book in the "*Public Health Engineer*."—This, as far as we are aware, is the first attempt to collect in a handy and fairly popular form the existing data upon which are based our knowledge of the behaviour of sewer gas.

In his Preface the author says:—"Questions affecting Nature, and the processes by which she works her marvellous changes, should, in the author's opinion, not be looked upon from one standpoint only, but ought to be viewed in their entirety and with their surroundings, otherwise one is apt to exaggerate the importance of one or more symptoms and leave others—equally important, or perhaps more so—altogether unobserved. It is, therefore, to the harmonious working together of a number of specialists, such as the chemist, the medical man, the bacteriologist, botanist and engineer, that the author looks for the true answer concerning a number of questions affecting the health of individuals and communities." It is in this thoroughly unbiased and scientific spirit that the author approaches his subject.

Mr. ROCHLING divides his treatise into six parts, to which are added as many as 12 appendices.

The first part deals with general considerations. The author, while insisting on the importance of the subject, points out that no comprehensive treatise on the influence of sewer gas on health has hitherto been published in any modern language, and then goes into the history of the sewer gas controversy in England and foreign countries. The author then points out that we still know very little of the changes which fecal matters undergo after evacuation and insists very strongly on the advantages of the water carriage system when properly carried out. Of course the most interesting part of the work is that which deals with typhoid. After briefly referring to MURCHISON's theory of the spontaneous generation of typhoid fever by sewer gas, and its demolition, Mr. ROCHLING says:—

"Although by no means universally accepted, it is now generally held that the typhoid-exciting cause is the bacillus typhosus, a microbe which was discovered probably by EMBERT, KOCH, MEYER and GAFFKY."

In Part II. Mr. ROCHLING deals with observed cases of injury to health from sewer gas. Chapter I. of this section is devoted to a consideration of cases in which outbreaks of typhoid fever have been traced to sewer gas, and gives BUCHANAN's investigations. In Appendix IX these cases are briefly recorded. A very interesting chapter goes into cases of coincidence of typhoid fever and faulty drains, and gives the experience of Leicester, Bristol, Hornsey, and Leeds. The Birmingham sewer-gas case occupies a chapter by itself. After going into the debatable question of the health of sewer men, and giving instances of septic poisoning through sewer gas, the author proceeds to tackle the question of analysis, and especially of micro-organisms in sewer air.

From this section we cannot refrain from quoting the following admirable passages:—

"Assuming, for the sake of argument, that the bacillus typhosus is the true cause of typhoid fever, it must not be thought that it is present in every litre of sewer air, but being only an occasional and periodical inhabitant of it, it would be found only in isolated places. It is, therefore, a mere accident if the experimenter happens to take his samples of air in a locality where the typhoid germs are, and just at the time they are passing his place of observation in an air current; the next moment they might be wafted away and beyond his reach. Further, in a large sewer they might pass round his instruments, and so escape him. It is clear, there-

fore, that their chances of not being taken in isolated samples of sewer air are innumerable, and the chances of catching them extremely remote. These or similar circumstances may account for the fact that only one observer (Uffelmann) has up to the present been able to discover the pathogenic germ of suppuration in sewer air."

In another passage he says:—

"Therefore, those who look upon sewer air as capable of carrying the typhoid germ are in no worse position than those who hold the water responsible for some outbreaks of typhoid fever."

In other words, the difficulty of finding the bacillus typhosus in water is as little destructive of the sewer-gas theory as the failure to find it in sewer-air is destructive of the water-borne theory.

We will conclude our notice of this most fascinating work, which should be read by everybody who takes the slightest interest in sanitation, by quoting a few passages from the author's concluding chapters.

"When the history of the sanitary progress during the present century, which is now fast sinking into its grave, comes to be written, a very important place will have to be assigned to what has been termed the sewer-gas theory, as it has exerted a most powerful influence for good in the matter of house and general sanitation; indeed, it has been stated that the results, which the conviction that sewer air or sewer gas is dangerous to health has brought about, surpass in brightness, excellence, and importance the results achieved by any other sanitary doctrine."

Further on he says:—

"Sewer air or sewer gas has the power of predisposing the constitution to typhoid infection, so that if the typhoid bacillus (and probably also others) is introduced into the system in some way or other after exposure to sewer gas, it finds there a favourable soil for committing its ravages."

Mr. ROCHLING quotes Professor BOSTOCK HILL's paper on a case of poisoning at Sutton Coldfield, and also the very interesting experiments of Dr. G. ALESSI in Rome. Altogether this is a most excellent work.

DR. M. C. KELLER ON "FLOATING KIDNEY IN WOMEN."

HAVING passed in review and discussed the different causes which have been put forward to account for the condition, Dr. KELLER in the above named work which is published in Germany, directs special attention to the points which are likely to interest the accoucheur and obstetrician.

He does not think that pregnancy is likely to favor its development; for by increasing the internal pressure of the abdomen it rather tends to restrict the movements of the kidney.

On the other hand after childbirth, there is a sudden decrease of the internal pressure, and in proportion to the extent to which the abdominal walls have been distended, they are now relaxed: this condition is favourable to movements of the kidney.

Consequently M. KELLER recommends as a isophylastic measure that an abdominal belt should be worn during pregnancy, especially if the abdomen is large; to favour the regression of the abdominal walls the lying-in woman should remain in bed, supine, for at least three weeks and not sit up before the 17th day; the intestinal functions should be regulated, and if there is any difficulty in passing water it is better to pass the catheter than permit straining.

He recommends that a belt should be worn for at least six weeks.

The same precautions are necessary after the removal of large abdominal tumors.

The author does not believe that displacements of the position of the genital organs, such as displace the kidney.

The author also connects which exists between the kidney and the genital organs, and remarks that if a floating kidney is associated with disease of the uterus, it is often difficult to determine the part played by each of these organs in the causation of painful symptoms.

It is often impossible to decide except by treatment.

It is rare to find a movable kidney confounded with an ovarian tumor, and more rarely still with a uterine tumor. Still it happens that the kidney is found in the pelvis and perhaps adherent to the uterine appendages; while on the other hand an ovarian tumor may be fixed in the lumbar region and thereby the diagnosis made very difficult.

In general however as M. KELLER says, the movable kidney is easily recognised, only it is not thought of. Further, in every case where the genital organs do not account satisfactorily for the symptoms of the patient, it should be ascertained that the kidney is in its right position.

M. KELLER gives the following advice regarding treatment. Endeavours should be made to limit the movements of the organ by an abdominal bandage reaching up to the umbilicus, and tighter below than above. Pads should not be used, for they are useless and even injurious.

A bandage should always be tried in the first instance and only in cases of absolute necessity should nephraphy be performed, the result of which is often only transitory.

As a last resource nephrectomy may be necessary.

PROFESSOR D. D. CUNNINGHAM, M.B., F.R.S., C.I.E.

MR. J. P. HEWETT, C.I.E., Secretary to the Government of India sends the following State eulogium on Dr CUNNINGHAM's services to the Director-General of the Indian Medical Service.—

"I am directed to say that, on the retirement from the service of Brigade-Surgeon-Lieutenant-Colonel D. D. CUNNINGHAM, M.B., F.R.S., C.I.E., Professor of Physiology, Medical College, Calcutta, and Special Assistant to the Sanitary Commissioner with the Government of India, the Governor General in Council desires to place on record his high appreciation of the eminent services rendered by him to the State.

2. After distinguishing himself at Netley, Dr. CUNNINGHAM proceeded to Germany in company with the late Dr. T. LEWIS to study the so-called fungoid theories of the causation of cholera, and on arrival in India he was placed on special duty to investigate this subject. His first paper thereon was published in the seventh Annual Report of the Commissioner with the Government of India and gained for him the warm approbation of Her Majesty's Secretary of State for India. From that time until 1879, Dr. CUNNINGHAM was continuously engaged in the study of the Etiology of Cholera and cognate and similar subjects, and published a series of papers, mostly in collaboration with the late Dr. T. LEWIS, including "Microscopical researches into the Agent or Agents producing cholera" (1871-73), "The Fungus disease of India" (1874), "The soil in its relation to disease" (1874), "The Oriental sore as observed in India" (1875), "Leprosy in India" (1875), "Cholera in relation to certain physical phenomena" (1876). All or nearly all of these contributions are classical and have secured the names of LEWIS and CUNNINGHAM familiar to students of tropical hygiene and of tropical medicine.

3. In 1879 Dr. CUNNINGHAM was appointed to the Chair of Physiology in the Medical College, Calcutta—a post which

he continued to occupy till he was compelled to take sick leave last year. By his zeal and devotion to his work he introduced a high standard of efficiency in the teaching of Physiology in the College. He was the first Professor to demonstrate histological preparations to the students in a systematic way, and also the first to teach them the practical use of the microscope. His generous sympathy with the earnest student and his unusual appreciation of all the best features in the character of his pupils enabled him, to stimulate in a high degree the growth of scientific thought amongst those who attended lectures. It is difficult to exaggerate the effect of his personal influence in the development of medical education in Bengal, and the Government of India anticipate that it will be long before it ceases to be felt in the College.

4. In 1884, while the controversy regarding the significance of KOCH's great discovery of the comma-bacillus was becoming acute, Dr. CUNNINGHAM was appointed Special Assistant to the Sanitary Commissioner for the purpose of investigating this problem, and the results of his labours have added to his reputation among Scientists throughout Europe.

5. Dr. CUNNINGHAM's most recent labours have been directed towards investigations connected with Snake-bite and the discovery of remedy. In the course of these investigations he has been successful in clearing away many serious errors.

6. Dr. CUNNINGHAM has twice received the thanks of the Government of India for reports submitted by him in collaboration with the late Dr. LEWIS on the Oriental or Delhi sore (1877), and Cholera in relation to certain physical phenomena.

7. In 1885 he was made an Honorary Surgeon to His Excellency the Viceroy. In 1891 he acted as delegate to the Congress of Hygiene and Demography of that year. In 1893 he was created a Companion of the Order of the Indian Empire and in 1894 he was deputed to Rome to represent the Government of India at the International Medical Congress.

8. By the retirement of Dr. CUNNINGHAM, the Government of India lose the services of one of the most distinguished of the scientific men who have served them, the Indian Medical Service one of its most eminent Members, and yourself an invaluable adviser. He carries with him on his retirement the warmest thanks of the Government of India for his long and distinguished services.

ANALYSIS OF AIR.

THE Public Health Engineer has some very apposite remarks to make on the subject of Air Analysis. As to the quality of the air, we consume, we generally know nothing. "We certainly have found means of expelling the air from our dwellings, but are we not a little careless about the quality of air we introduce? It may come to us from the ventilating shaft of a sewer, it may contain in it the unconsumed products of combustion of a factory, or the fumes of a neighbouring gas works. For all we know the air introduced into our rooms may be just as bad as the air we have expelled.

WAXLEY and COOPER are quoted as saying. "The air of Churches ought to be rigorously examined for reasons which need not be particularly mentioned. Deterioration of the air is the result of fermentation, putrefaction, inspiration and combustion, and whenever these processes take place, there must be vitiation of the atmosphere, unless there is a free circulation of air. In short, the inside of all buildings affords scope for air analysis and the question which air analysis enables us to answer is this—Is the ventilation of the building sufficient?"

The Public Health Engineer continues "We have our water supply periodically tested by experts, is it not still more important that the air of Churches, Theatres and other places, where people most do congregate should be analysed also."

We know that the more foul a sewer is the more does it pollute the air it ventilates into. So well is this recognised that the most modern sanitary authorities affirm that the primary duty of the sanitarian is to prevent the sewers from getting foul at all.

If you keep the sewers sweet you do not pollute the air we breathe, that is very evident. Is not the same thing true of houses, and more especially of large colonies of houses, of towns, and particularly of manufacturing towns? These centres of population send into the atmosphere out of their badly-ventilated dwellings and factories, dense volumes of vitiated air, by which the entire town is polluted, until it becomes a danger to live in such a town; and medical authorities declare that the denizens of towns become in the third generation stunted in growth, emaciated and miserable, and eventually die out.

ENTERIC FEVER AND WATER SUPPLY.

SOME remarkable and unexpected results have recently been put forward by Mr. A. H. SMITH, the Chief Medical Officer of the Gresham Life Assurance Society, which show in a broad way that the mortality from Enteric Fever in various English and other towns is higher when the drinking water is obtained from either moorlands or chalk than it is when the supply is drawn from rivers and efficiently filtered.

These results are remarkable because they are at variance with what is usually taught in text books with reference to the selection of water supplies.

"They show that proper storage and filtration of river water and the action of light and air have a remarkable effect in reducing the risk of fever."

"Among the towns deriving their water supply from the chalk, Mr SMITH instances the following death-rates from fever per million living in 1896 Hull, 280, Norwich, 193, Epsom, 190 (mean of 10 years), Portsmouth, 158. Among towns receiving their supply from upland and moorland surfaces are Belfast 580, Dublin 455, Liverpool 822, Glasgow 223, Leicester 304. Among towns supplied by filtered river waters are Hamburg 58, Cologne 49, Frankfurt 42, Altona 41, while London, supplied from rivers and chalk, has a death-rate from enteric fever of 187 per million living. Taking the death-rates for the first three quarters of 1897, the results are more discrepant. Thus, Croydon (supplied from deep chalk wells) had a death-rate from enteric fever of 78, Portsmouth (chalk wells) of 185, Birmingham (partly wells in red sandstone and partly upland surface water) 180, London 79, Bradford (upland surface water) 82.

There are of course exceptions to this general rule, one of which Bristol, is pointed out by the *British Medical Journal*.

No doubt as Mr. SMITH admits "Other considerations must be taken into account besides the source of the supply."

Let these considerations, however, be what they may Mr. SMITH's broad generalisation is a very curious and valuable one and we hope that it will lead to further investigations being undertaken.

The whole of our ideas concerning the part played by water in the production of Enteric fever, have lately tended to run in very narrow lines, and a widening of the outlook will be a very acceptable change.

In helping to bring this about Mr. SMITH has done yeoman's service.

MEDICAL SLANDER.

THESE is an old adage which says, "an idle brain is the devil's workshop." This idle old truth had been strangely verified in Calcutta quite recently in the person of a youthful gay lothario of the Indian Medical Service, whose office is a perfect sinecure, since he is little more or less than a sort of camp follower or superior clerk. It is an appointment that demands nothing worth the name in the way of scientific ability, nor the glamour of a professional reputation, nor anything else to command respect or admiration. Failing to fatten on his handsome State salary and thus to become lethargic in both body and mind, he utilises his vast unemployed energy in torturing the minds of others by blackening characters and retelling unavowed morsels of slander into unwilling ears. True to his satanic instincts, he breathes out poison caring little for its insidious and dire effects, and when hunted, in order that he might be pilloried and punished for his crimes, he shrinks into his hiding place, "a refuge of lies." Conscious of the ever present fact that his official position with its assured income does not need an unblemished character to establish and support it, he is oblivious to the stern reality that the practising physician knows that the mainstay, the sheet anchor of his success, necessitates the straining of every effort to maintain a blameless record in thought, word and deed. To attack the practising physician's moral character, is to rob him of a priceless jewel and to deprive his children of their bread. It is impossible to denounce a slanderer in sufficiently scathing terms. Slander is a mean, cowardly, contemptible crime, a moral defect which cannot be gauged either in the depths of its depravity nor in the enormity of its baneful consequences. Once uttered, the hateful breath of slander permeates the longest span of human life and throws a dark shadow along its otherwise happiest and most prosperous career. We often wonder if men pause to consider the eternal heinousness of this worst of all social and moral sins, which never fails to find a Nemesis sooner or later.

Had this moral monstrosity—who unfortunately belongs to the medical fraternity—considered for a moment, the poisonous effects of his dark and shady dealings, he would never, as he has done quite recently, have vilely slandered a non official physician to one of his patients, nor would he, unless he were a perfect sample of the true genus of scandal-monger, have resorted to the cowardly device of denying the authorship of his slanderous statements, when threatened with a criminal prosecution. The "refuge of lies" is not always an invulnerable shelter, but the vision of threatening justice, will, it is hoped serve to warn this slanderer and one or two others of his ilk, that the throwing of stones is a dangerous practice, for like a boomerang, a stone has been known to rebound and destroy the hand that sped it on its evil mission.

THE RESPONSIBILITY OF MEDICAL EXPERTS

SAYS the *Lancet*—"Public attention is once more directed to the case of Dr. MELOON whom the *tribunal civil* of St. Nazaire last year ordered to pay 1,000 francs (£40) damages to a woman accused of abortion. Dr. MELOON, who was the expert entrusted with the duty of examining the accused, believed that in all probability abortion had recently occurred. The woman's refusal to answer certain questions and her contradictory statements induced him to make a guarded diagnosis, and three days afterwards she was delivered of a five months' foetus; she had been arrested after his report was presented, but was immediately released, and believing that his mistake carried with it responsibility for her arrest she brought an action for damages

against him. The effect is giving judgment against Dr. McLOUGH, blaming him for not having made a chemical examination of the blood, entering thereby into scientific questions the important knowledge of which led to absurd expressions of opinion. This judgment was reversed by the Appeal Court on several grounds. Firstly, because the medical man in question had acted with all necessary prudence and had only given an opinion that there was a great probability of abortion having occurred. Secondly, this judgment, by affirming the responsibility of medical experts, would render their action impossible for the future. The medical expert is fallible. When he is consulted by a magistrate it is his duty to give a candid opinion and it is for the magistrate to obtain further information by reference to another expert, if the report of the first one leaves him in uncertainty. An expert who, like Dr. McLOUGH, describes an offence as being highly probable could not be responsible for the conclusions which the magistrate, irresponsible himself, draws from the medical man's undecided opinion. Under these circumstances the case came before the Appeal Court of Rennes on 26th May, and judgment was delivered on 3rd June, reversing the judgment of the *tribunal civil*, and declaring that Dr. McLOUGH had acted prudently in not giving a positive opinion in a difficult case and in not committing himself to more than the probability of the condition referred to. Furthermore, it could not be said that the opinion given by Dr. McLOUGH was the immediate cause of the arrest. This belongs to the province of the magistrate and consequently the medical expert cannot be held responsible for it.

THE C. D. ACTS IN INDIA.

A LONDON correspondent sends us the following paragraph for insertion — A Memorial, signed by upwards of 1,000 mothers in various parts of the kingdom, has been forwarded to Lord SALISBURY by the Countess of Carlisle, protesting against the principle involved in protecting the health of British troops by means of the medical supervision of women. The Memorialists consider that such measures practically concede the reasonableness of vicious indulgence, and its right to protection by the State at the cost of others, thus giving it an appearance of State sanction, and that the demoralising influence thus created must necessarily spread from the army into civil life. They see reason to fear that such methods may, as heretofore, be extended and strengthened, in a manner more and more damaging to the national character; and they see no reason to hope that they will even then prevent the spread of disease, as they have hitherto proved almost or quite unavailing for that purpose. Much as they would dread the return of their own sons from foreign service wasted by revolting disease, which might be transmitted to their posterity, they would dread no less their return as dissolute and hardened men, expecting to have a class of women placed at their disposal under safe conditions by the State; and they urge that the State is rather bound to protect the young men who enter its service as well from moral as from physical contamination. They believe that a rapid and permanent diminution of disease is more likely to be brought about by the promotion of a higher moral standard throughout all ranks of the army, by maintaining the principle recently laid down by the Viceroy of India, that vicious indulgence, which unfits a man for service, must rank with treachery and cowardice as a sin unworthy of a soldier; and by the adoption, throughout the army, of judicious methods of discipline and encouragement, combined with a minute watchfulness of the progress made, and the special commendation of those officers who are most successful in promoting good conduct, and diminishing vice

as well as disease among their men. Finally, they also urge upon the Government their responsibility towards the women of the rising generation, who must either share of suffer from the demoralisation produced—a demoralisation which cannot but impair both the sanctity and the happiness of the English home."

A SCHOOL OF TROPICAL DISEASES.

A proposal is on foot to establish a school of Tropical Medicine in London.

It appears that the Seamen's Hospital Society propose to utilise the large amount of clinical material in their hospitals and dispensaries for practical instruction in tropical diseases. With this object they have it in contemplation to build school premises, including residential quarters for eight students at their Albert Dock Hospital, which will be enlarged to accommodate forty patients. The staff at Greenwich and at the Albert Dock Hospital will be invited to co-operate with the Society in this new undertaking. The course of instruction will be based on a definite plan; the syllabus covering all the more important tropical diseases. The course will extend over a period of two months, and thus five batches of students will pass through the school every year, leaving August and September free for vacation. The residential system is considered desirable because of the distance of the school from town and because men will thus have opportunities of continuous observation so essential in the case of certain tropical diseases. Provision will also be made for non-resident students. For the residents an inclusive fee of 4 guineas a week is suggested, this amount covering all expenses of instruction, board, and lodging. For non-residents the fee will of course be considerably less.

It is estimated that a sum of £10,000 would be required to place the School of Tropical Diseases on a solid footing. In a country where the practical importance of scientific knowledge is better appreciated by the Legislature than it is here, the money would be given for such a purpose without hesitation.

A scheme of this description should certainly receive government support, and in the present instance there is every hope that it will. We hope soon to hear that the new school is safely launched.

THE MICRO-ORGANISM OF BERI-BERI

In the *Lancet* of June 25th, Dr. WALTER K. HUNTER publishes a "Note on the Etiology of Beri-Beri based upon two cases in the Glasgow Royal Infirmary. He concludes "that the white staphylococcus of PAKETHAENG and WINKLER is in truth the specific micro-organism of beri-beri."

In both these cases specimens of freshly-drawn blood were examined at various times and on each occasion micro-organisms were to be seen in rapid motion in the spaces between the groups of corpuscles.

These micro-organisms were successfully cultivated and rabbits inoculated. When killed the *post-mortem* examinations were negative as far as naked eye appearances go but the nerves showed unmistakable evidence of parenchymatous degeneration.

The food of the two patients, one a native of Bombay and the other a native of Zanzibar, consisted of rice, split peas and two kinds of dried fish; from these, cultivations were made with the result that from the rice there was readily cultivated a white staphylococcus with similar morphological characters to the staphylococcus *beri-beri* which was grown from the blood of the two patients. This staphylococcus which was grown from rice liquefied gelatin in 19 days. Its pathogenic properties were tested

by ingesting a fourth rabbit. The ~~two~~ ^{white} ~~staple~~ ^{staple} ~~was~~ ^{was} ~~readily~~ ^{readily} ~~culivated~~ ^{culivated} ~~from~~ ^{from} ~~the~~ ^{the} ~~blood~~ ^{blood} ~~of~~ ^{of} ~~the~~ ^{the} ~~rabbit~~ ^{rabbit}. Dr. SURVEY concludes that this white ~~staple~~ ^{staple} ~~was~~ ^{was} ~~grown~~ ^{grown} ~~from~~ ^{from} ~~rice~~ ^{rice} ~~is~~ ^{is} ~~the~~ ^{the} ~~same~~ ^{same} ~~white~~ ^{white} ~~organism~~ ^{organism} ~~as~~ ^{as} ~~that~~ ^{that} ~~which~~ ^{which} ~~was~~ ^{was} ~~found~~ ^{found} ~~in~~ ⁱⁿ ~~the~~ ^{the} ~~blood~~ ^{blood} ~~of~~ ^{of} ~~the~~ ^{the} ~~two~~ ^{two} ~~patients~~ ^{patients}, and therefore considers that ~~they~~ ^{they} ~~taken~~ ^{taken} ~~might~~ ^{might} ~~may~~ ^{may} ~~be~~ ^{be} ~~a~~ ^a ~~source~~ ^{source} ~~of~~ ^{of} ~~infection~~ ^{infection}.

THE INDIAN MEDICAL SERVICE.

THE second annual dinner of the Indian Medical Service was held at the Grosvenor Restaurant, London, on 9th June, and it is hoped that the agreeable opportunity thus afforded for summing old friends will become an annual event. The chair was taken by Sir JOSEPH FAYRE, Bart., M.D., and, after the usual loyal toasts had been honoured, Surgeon-General DR. EWEY proposed that of the dinner service. This was acknowledged in a very telling speech by Surgeon-General JAMISON, C.B., the Director-General of the Army Medical Department. He referred to the brotherly feeling which existed between the medical services of the army and of the navy, and to the even more intimate relations between the army and the Indian Medical Service. He claimed for the military medical services that they discharged their duties to the Empire in a manner which had not been surpassed by the medical service of any other country, and he enforced his claim by a reference to the comparative mortality of expeditions recently conducted by France and by Great Britain. He concluded by proposing the toast of the Indian Medical Service, which was acknowledged by Sir JOSEPH FAYRE. The toast of "The Guests" proposed by Sir JOSEPH EWEY was acknowledged by Sir A. DOUGLAS POWELL, Bart., and Dr. SANBORN. Due acknowledgments were also expressed to the Chairman and to Mr. P. J. FRYER, the Honorary Secretary. Before the company separated Sir JOSEPH FAYRE made some weighty remarks upon the new army warrant which Lord LANSDOWNE has promised to issue constituting a Royal Army Medical Corps. He emphatically repudiated the allegation that the medical officers desired general military command, they did not desire to step out of their proper sphere, but they claimed that within that sphere they should have a defined position, and should possess definite army rank. This, he said, was essential in the interests of the service as a whole, for without it the medical services could not discharge their duties to the army at large with efficiency.

THE REGISTRATION OF MEDICAL PRACTITIONERS IN INDIA.

THE *Philadelphia Medical Journal* says—"At the present moment it is open for any uneducated and unqualified person to practise medicine in India, while the sumptuous imagination of the Oriental offers a premium on quackery. Quackery is therefore rampant, but the English Secretary of State for India, Lord George Hamilton, has recently declared in the House of Commons that he does not see his way clear to apply the only possible remedy, viz., a strict system of registration, which should make it unlawful for any except duly qualified persons to live by the practice of medicine. His lordship refused to introduce to the House or to support a bill for the registration of medical men in India, on the ground that it was natural that the natives should resort to native practitioners; and so far his attitude was in keeping with the best traditions of Anglo-Indian Government. The greatest respect has always been shown for native prejudices, although the sacred duty of every nation to progress has been considered before these prejudices. At the same time Lord GEORGE HAMILTON's decision is open to criticism. The ter-

mination of an official list of registered practitioners would be in keeping with native habits of mind. It does not make the practice of unqualified persons illegal. It would simply provide a means whereby the natives and the white man too would know at once the qualified man from the unqualified, and if, with such means at his command, a man should choose to employ the unqualified the result must be regarded as of his own seeking.

INTERMENTAL BURIAL.

THE dangers which may arise from intermental burial are well represented by the case of the church of St. George-the-Martyr, Southwark, which has, owing to the activity of "the Public Health Engineer" recently attracted a large amount of attention in London.

It appears that the atmosphere of the church is being poisoned by effluvia from the crypt which was formerly used as a burying place. Dr. WALDO the Medical Officer of Health stated, "that he had examined the crypt and found many coffins worn out and bones scattered upon the ground. A large crack in the wall would allow effluvia to escape into the church." "He considered the condition of the crypt dangerous to health. There might be 2,000 bodies in the crypt and the effluvia was very strong."

Professor WANKLYN and Mr. W. J. COOPER were deputed to make a chemical examination of the air; they reported that it contained 20.65 volumes of carbonic acid in 10,000 volumes of air, and they expressed the opinion that it was "dangerously impure." So we should think considering that this is more than 3 times the maximum of permissible impurity according to the best authorities.

How to get the bodies removed is now the practical point, but as the cost will be \$1,000, none of the authorities appear anxious to undertake the task, and a good deal of ill-feeling amongst those immediately concerned, is the natural, if quite illogical result of the publicity so suddenly bestowed upon them.

ONE VIEW OF THE ANGLO-INDIAN PROBLEM.

MR. ANDREW WILSON, in his excellent book *The Abode of Snow*, page 73, says—

"In the North-West Provinces, however, while personally liked, (the viceroy) much animosity was excited, especially among non-official Englishmen, by what was considered to be his undue favouritism towards what are called the educated natives. I was somewhat surprised at the depth and fierceness of the resentment which had thus been excited. One man in a responsible position, went so far as to say that the next rebellion in India would be on the part of the Europeans and Eurasians, and that when such a movement arose, every English soldier who had been six months in the country would be on their side. This may appear very absurd to Indian officials, who know little of the passions raging in the hearts of the people round them, whether natives or Europeans but I think there is something in it, and that it correctly enough indicates the existence of feelings which are not without some ground. Another remark of this man, who was educated, shrewd, and had a wide and varied experience of the world, is worth noting, without attaching to it more importance than it deserves. He said: 'The civilians think that India was made for themselves and the natives alone, and it is becoming every day more impossible for non-official Englishmen to live in the country; but the natives are discovering that the civilians are quite unnecessary also, and it will end in our all having to go together like the Englishmen to England, and the natives to massacre, famine and pestilence.'

ARMY MEDICAL OFFICERS AND NON-EFFECTIVES OF THE ARMY MEDICAL DEPT. AND INDIAN MEDICAL SERVICES.

THE A. M. S., it appears, lost all its highest numerical strength during the sixties, when it included within its folds about 1,100 martial medicals. For a considerable time subsequently the average strength was 900; but in its present depleted condition, the A. M. S. only numbers some 800 multi-talented officers. The non-effective list contains about 370 men; but of these 120 are liable to recall on the occurrence of emergencies, and 94 are actually filling retired pay appointments. The Unemployed Non-effectives thus amount to about 260; while the absolute non-effective—that is to say, those who are above 55, and are not liable to recall—come up to 200. Thus there are, on an average 30 non-effective to every 100 effective medical officers. As there are 7,500 officers on the non-effective list, the total number of Army Medical non-effectives (*viz.*, 370) form 5 per cent of the numerically formidable non-effective brigade. With regard to the Indian Medical Service, the non-effectives number 800; while the average strength may be set down at 600, and perhaps slightly over this number. Thus there are nearly 50 non-effectives to every 100 officers on the Active List; and the Indian Medical Service supplies 4 per cent. of the total non-effective list of the Army, while both the medical services combined account for 9 per cent. of the grand total of Army non-effectives.

INDIAN AND ANGLO-INDIAN VERSUS BRITISH PLAGUE DOCTORS AND PLAGUE NURSES.

WE invite correspondence and comments on this subject which is of considerable importance to India and Indian finances. At no time has greater point and significance been given to the injustice and the criminal cruelty of the Indian Government in the matter of its disregard of the claims, the qualifications, the rights and the privileges of local medical and nursing talent, than in the importation of British doctors and British nurses for dealing with plague and plague patients in India. That both these imported agencies were absolutely unnecessary, in view of the abundance of qualified material in this country, is proved by the ludicrous failure of the material sent out by the Secretary of State for India. If anything has recently been done by the Government to cause a most righteous and indignant denouncement of its heartless dealings with the aspirations and the legitimate claims of the people of this country it is to be found in the appointment of outside labor when indigenous material of as good and even better quality was available and at hand. We shall have much to say on this matter, but at present we invite public criticism on the subject.

ANGLO-INDIANS AND THE IRISH CAUSE.

WHEN GLADSTONE was spending his last few days on earth at Bournemouth, he wrote a characteristic letter to one of the leaders of the Irish Cause—MR. DILLON, M. P. The following paragraph from that letter dated the 9th March 1898, is peculiarly expressive of the socio-political condition of the Irish people as also of Anglo-Indians. Both the Irish and Anglo-Indians are oppressed by a form of government that is very galling to them, both these peoples have grievances common to each other in their disabilities and in the denial of their rights and privileges, and the advice of the greatest of modern English statesmen is embodied in these few words of GLADSTONE'S pathetic lines to Mr. DILLON:—"Your cause is in your own hands, if Ireland is distressed, her cause so long neglected, is, if on the contrary, she knows her own mind and is in a spirit, that cause is irresistible." May

Godward was the pathway to liberty and freedom that opens up to her, if she will but follow the Grand Old Man's advice. Anglo-Indians will and in these prophetic lines a complete and perfect reiteration of Lord DUFFERIN'S well-balanced opinion. He said exactly the same thing of the Anglo-Indian race in India. **UNITY AND SUCCESS** are synonymous terms. Let Anglo-Indians meet them aright.

CALCUTTA PLAGUE SPOTS.

THE residents of Upper Circular Road have once more memorialised the Municipality in reference to the removal from that locality of the disgusting and filth-laden platform which pollutes the air and spreads disease around. These platforms were erected some thirty years ago when the conditions of the city were different from those obtaining now, and can find no possible justification at the present time, especially when plague is stalking through the city. In the words of Dr. SYMPSON these platforms, apart from the effect they have of seriously depreciating the value of property, are injurious to the health of those who live near them on account of the "breathing and swallowing of the filth which is wafted by the air into their houses." He adds: "The inhabitants of Circular Road are subjected to a serious nuisance, and a fine street is depreciated in its property value." The nuisance, in fact, is so great and so overpowering, that during the rainy season some of the respectable inhabitants are compelled to leave their houses and seek shelter elsewhere. We understand that a resolution was passed some time ago by the Commissioners sanctioning the removal of these disease-manufacturing platforms. It is high time that this resolution was given effect to, for it is no credit to Calcutta, or to the Municipality either, that such a festering plague spot should exist at the end of the nineteenth century within half a mile of Government House and almost in the heart of the Capital of India.

RADIOGRAPHY OF ARTERIES AND OF EXTRA UTERINE PREGNANCY.

AT the meeting of the Biological Society of Paris, M. TURBERT showed some radiographs, the first of which taken from a dead body, showed clearly the radial and ulnar arteries, and the course of these arteries could be followed even where their radiographic shadow was superimposed upon that of the bone. The vessels had not been injected. The second plate was taken from the foot of an old man. The anterior tibial artery could easily be seen and followed throughout the greater part of its course. These plates are the first where the shadow of the uninjected artery has been obtained. M. TURBERT also obtained some months ago a radiograph of a young woman, about twenty-five years of age, who had been sent to the hospital with a diagnosis of extra-uterine pregnancy. He was able to confirm this diagnosis in opposition to the opinion of some of his colleagues, who considered that she was suffering from either a hæmatocoele or a growth. The radiograph showed clearly the presence of a foetus of about five or six months, and the head and body and lower limbs were clearly shown upon the plate.

DIAMOND OUT DIAMOND.

THE recent death of Sir RICHARD QUAIN, who had been what some Americans might call a "hustler," has brought forward the following anecdote of London high-life practice. Dr. QUAIN, as the *London Practitioner* states it, had in a very high degree the power of inspiring confidence, which is of vital importance in the equipment of a successful city physician. He was a past master in the art of managing patients. There is a legend, however, that he was once driven from the field by a still more consummate artist. A financial magnate of LONDON had been suffering for a long time from renal

trouble of a grave character, and which it was considered expedient by QUAIN and other physicians in attendance to conceal from the family. The wife insisted, much to QUAIN's annoyance, on calling in Sir WILLIAM GULL, who, she said, would be sure to tell her what her husband was suffering from, which apparently none of the doctors knew. Gull, when interpolated on the subject, replied in his most oracular manner: "Madam, your husband is suffering from a coxhexia." "There," said the lady, triumphantly, "I knew Sir WILLIAM GULL would tell me."

THE DIPLOMA OF THE APOTHECARIES SOCIETY.

A CORRESPONDENT of *The Lancet* writes to that journal as follows:—"Sir,—With your permission I should like to make a few remarks respecting the late prosecution of a L. S. A. Lord, by the General Medical Council for describing himself as a physician and surgeon. I presume that the proceedings were taken under Section 40 of the Medical Act, 1858, for wilfully and falsely pretending to be recognised by law as a physician and surgeon. In 1858 the following letter was published in the leading medical journals:—

Society of Apothecaries, London,
Blackfriars, E. C., 27th Sept. 1858.

My Dear Sir,—The title of Surgeon has long been in use, implying medical practitioner, but the L. S. A. is a licentiate in surgery as well as in medicine. It cannot be said that he is not a surgeon. It seems to me he may call himself what he likes—physician if he pleases.

Yours faithfully,

F. P. MILES, Esq.,

T. FRANKLIN, M.D., Secretary.

After such a statement, publicly made and never challenged, I cannot see that a L. S. A. who describes himself as a physician and surgeon can be said to wilfully and falsely misdescribe himself. I have in perfect good faith described myself as a surgeon for several years and I contend that we are recognised by law as such. Sec. 2 of the Medical Practitioners' Act, 1876, says: "All legally qualified medical practitioners, with qualifications in medicine and surgery registered under 'the Medical Act' shall be capable of being elected surgeons to county infirmaries or hospitals in Ireland."

THE PASSING OF THE REFLEX.

DR. PATRICK (*Intercollegiate Medical Journal*), writes as follows: "And this leads me to mention what has already begun and what, God grant, may soon be consummated—the passing of the reflex. When to the nerve specialist comes a case of epilepsy, with a note from the family physician saying that the ovaries have been removed without effect, and so perhaps the trouble is in the brain; or a case of convulsive tic, with the message that the spasm has continued in spite of cauterisation of the turbinates; or as occurred to me a few days ago, he sees a born neuropath with typical traumatic neurosis who has undergone five pelvic operations for relief of her nervous symptoms—he groans in spirit and looks longingly forward to the millennium, when the man who operates shall have or procure an adequate understanding of that for which he cuts. In the meantime, under the keen scrutiny and rigid requirements of neurology, the so-called reflex as a cause of great nervous disorder is gradually being pushed into its rightful place—that is, among the relatively unimportant curiosities of etiology."

NEW HOSPITAL FOR BERLIN.

A PROJECT is on foot to construct a fourth grand hospital replete with everything that is required by modern hygiene, in the northern part of Berlin.

A sum of sixteen and a half million (marks we presume) will be devoted to the construction of the building. The hospital will cover an area of forty-seven hectares (114 acres)

of which thirty-seven will be taken up by hospital wards, which for the most part will consist of one storied pavilion.

There will be twenty-seven pavilions with a total of 1,650 beds.

Annexed to the hospital will be the Institute for infectious diseases which is supported by charity, a Lying-in Hospital and a School for the instruction of nurses.

The new establishment which will be completed in 1908 will be lighted by electric light and will comprise a hydro-pathic section with various baths, simple and medicated, a section for physical methods of treatment and especially for mesotherapy.

In addition to two Medical Directors and the heads of each department, there will be an assistant physician for each 50 patients.

THE "BRITISH MEDICAL JOURNAL" IN HYSTERIA.

WE note with amusement that the telegraphic account of Dr. KOCH's speech at the Colonial Society of Berlin on Malaria, which was wired to London, has caused the *British Medical Journal* to break out in a mild attack of Hysteria.

The result is a short leader entitled "Honor to whom Honor is Due" in the issue of 18th June.

The cause of the attack is not that Dr. KOCH claimed to have been the discoverer of the mosquito theory of malaria, for no such claim was put forward, but the bare suspicion that some people might think he had made this claim. This is surely carrying one's sensibilities a little too far, and such an outburst is hardly seemly in the columns of a sober and respectable, if lamentably dull Medical Journal.

Let it once and for all be known to all men that the *British Medical Journal* is the sole proprietor of the wonderful "mosquito" theory, and that only to mention it is to impinge proprietary rights. The managing agents and advertisers are MARSON BOSS and Co. We are sorry to say we have no faith in the evidence put forward as to the soundness of the concern, and cannot recommend it as a good speculation.

PLAGUE IN BOMBAY.

THE plague mortality, which began to decline in the middle of March, maintained a steady decline until the week ending the 7th of June. Since that week the mortality has shown an irregular record as follows:—

Week ending 7th June	44
14th "	36
21st "	15
28th "	58
5th July	38

These figures show that the decline has been regular and constant and has only increased in the last two weeks, when 58 and 38 deaths were recorded. Why the mortality should suddenly jump up from 15 in the week ending 21st June, to 58 in the next week, cannot easily be explained. It is true the mortality has again declined from 58 last week to 38 in the present week, but whether this second decline will continue, and for how long, or to what extent, is matter of pure conjecture.

CIVILIZED MANNERS FOR THE MEDICAL PRACTITIONER.

As the gentleness and sympathy of the Medical adviser very often effect half the cure the *New England Gazette* tells us that a doctor must learn to:—(1) laugh (2) tell a story, (3) keep his own troubles to himself (4) stop croaking, (5) hide his own pains and aches under a pleasant smile (6) not to cry and to (7) meet his friends with a smile, because while the good humoured soul is always welcome, the hypochondriac

or the dyspepsia is met always an insupportable nuisance. Besides which a good laugh and well told story are a god-send to a sick room. Then the world which is too busy to care for your ills or sorrows is just an indifferent to your pains and while tears do well enough in novels they are out of place in real life where it is kinder to do good, than harm, and paddling in dirty water must soil the paddler's clothes.

THE NORTH-WESTERN FRONTIER WAR.

We give the following abstract from a letter of a young army surgeon, which appeared in an English paper:—

"On the 25th, Christmas Day, we marched to a place called Karumma, which is a valley with about a dozen villages, with towers in each. A reconnaissance went out that day (two companies), and I sent my assistant in charge with stretchers, &c. All went well until the party was returning when the rear company was fired on by men who were concealed high up in a cave, the mouth of which was protected by a wall or sangan. It was too late to think of attacking the place. One man was killed at once by a shot through the head, and another man was wounded seriously in the knee. Military Assistant Surgeon BONHAM acted with great coolness, going back some distance under fire and bringing the men off on stretchers. The dead man was buried next morning early, in the valley just below our camp and some fodder was burnt over the grave so as to conceal the place of interment, as the Afridees are not above digging up a corpse in order to subject it to indignities.

STATE SANITATION IN INDIA.

THE *Indian Planter's Gazette* says:—"It is comforting and really reassuring to find one medical journal at least in this country which keeps a very keen eye on the failures of the Sanitary Commissioner with the Government of India. The *Indian Medical Record* of the 16th July, criticises with remarkable clearness and with pointed effect the erroneous conclusion into which the Sanitary Commissioner has been led by the statistical reports of the various presidencies and provinces in regard to the prevalence of enteric fever in this country in relation to water-supply. This dreadful scourge and its strange antics are very little understood, and what is worse still, nothing worthy the name, in the way of research towards the discovery of its causation, is being carried out, and this and other facts the *Record* exposes mercilessly.

THE PARKES' MEMORIAL PRIZE.

THIS Prize, founded in memory of the late Professor E. A. PARKES, M.D., F.R.S., and awarded triennially, is open to all medical officers of the army, navy, and Indian services of executive rank on full pay. The prize, which is of the value of 25 guineas, accompanied by a bronze medal, has been awarded this year to Surgeon-Captain FRED. SMITH, of the Army Medical Staff. The assessors were Dr. ARTHUR RAMSOME, F.R.S., Dr. JAMES NIVEN, and Professor HERBERT DUNLAP, M.D. of the Victoria University. The assessors also declared that Staff Surgeon W. W. PRYCE, R.N., and Surgeon-Lieutenant-Colonel ANDREW DUNCAN, Indian Medical Service, contributed essays of great merit. The subject was, "The Etiology, Prevalence, and Prevention of Diphtheria."

STEPS TO PREVENT THE SPREAD OF EPIDEMIC DISEASES BY SOLDIERS IN FRANCE.

In order to avoid the spread of epidemic diseases in France the Military authorities have issued an order that all men leaving the corps either on discharge or pension, must be medically inspected on order that those who are suffering from contagious diseases may be treated before their departure.

The same rule applies to men going on furlough, who are to be kept back if they present symptoms of even slight

and non-contagious affections. Commanding officers are as much as possible to grant leave, in suitable cases, to sick men to return to their native places for cure, and will regulate the length of the leave to the probable time required for the cure of the malady.

THE DEATH OF "SIR ROGER TROBROWNE."

THE hero of the extraordinary Tiebhorne trial has just died in London. Although it is now 27 years since the litigation began, which terminated 5 years later in the recently deceased man being condemned to 14 years penal servitude under the name of ARTHUR ORTON, public interest in the case has not entirely died out. All the English newspapers are giving short résumés of the proceedings at the trial. ORTON was largely convicted on medical evidence, as the indelible nature of certain scars and vaccination marks ruined his case.

A CURIOUS LAWSEER.

A VIENNA specialist received \$35 for ridding a man of a tapeworm. Afterwards the patient thought he had paid too much and demanded \$30 back. The doctor demurred and was sued. He could not, he argued, put the tapeworm back where he took it from, and if he could he was not sure that either the patient or the law would let him. Besides, the tapeworm was dead. The patient complained that it was only a short one. The doctor said he could not fine any precedent for removing tapeworms at so much per yard. Finally the doctor gave the patient back \$2 50!—"Literary Digest."

SHORT ITEMS.

Dr. Baghavandra Row, who was elected by the Committee of the Tata Higher Education Scheme to proceed to England to read Medicine in general, and Bacteriology in particular, having obtained the Degree of M.D. of the London University in 1897, has now been elected to the Grocers' Company's Research Scholarship of £250 to proceed to Bombay to undertake an investigation on the Typhoid Fever Bacillus. This is the first distinction conferred upon an Indian from amongst a large number of scientific English workers, who applied for the Research Scholarship. Dr. Row will leave England early next month, and will work in the Petit Laboratory.

The committee to consider the improvement of Field Hospital equipment has commenced its sittings at Simla. The President is Surgeon-Colonel Townsend, lately Principal Medical Officer with the First Division, Tirah Expeditionary Force, and the Members are Surgeon-Majors Burke, Shearer, and Duncan. The principal matter that will be taken into consideration will be the question of improving the mobility, by lessening the weight of appliances.

A very sad case is recorded from Bombay of the death of an European student who, while helping the Professor of Pathology to perform a *post-mortem* examination in a case of plague, accidentally cut his finger. The lad, who is described as "a promising and industrious student, and a conscientious worker," contracted plague and died within a week of the date of the wound. Two similar fatal cases of plague, contracted by *post-mortem* wounds, have lately occurred in Calcutta.

Rumour has it that Lieutenant Col'nel George Ranking M.D. I.M.S. intends while on furlough placing the grievance of his unjust removal from the Superintendentship of the Presidency General Hospital before the Secretary of State for India. Unquestionably it is unfair to offer and even to give a medical appointment to a professor of Oriental languages and Shakespeare, and then to snatch the gift from him. However let us see what that hateful bugbear of an India Office does to soothe a *rankling* spirit.

The rules and regulations for the Calcutta plague nurses are being freely commented on at Bombay among the plague doctors and nursing sisters as cruel and insulting. Several

of the latter to prevent off duty going to the closing of the hospitals, and whose services at the disposal of Government, have expressed their determination to resign rather than accept a transfer to Calcutta under such conditions.

On Dr. King's return from furlough, Surgeon-Major Henry Thomson, acting as Sanitary Commissioner, Madras, will take up the duties of Deputy Physician to the Maharaja of Travancore, in succession to Surgeon-Lieutenant-Colonel Ramsden White, whose period of service in that appointment has expired.

A Farmer waiting-master, laid information against Dr. Bahadurjee of Bombay charging him with offering indignities to the body of his child, by exposing it to view at the hospital in a glass bottle in spirits of wine. The Magistrate consented to call on the accused to show cause why a process should not issue.

A proposal has been made to Government by a powerful syndicate in London to make a permanent railway bridge over the Hooghly and to connect the railway lines of Howrah and Serdikh to a large central station in Calcutta. For good or evil this gigantic proposal needs consideration from a sanitary point of view.

In spite of "make-belief" to the contrary, "the Risley-Plague" of Calcutta which so accommodatingly and reverently observes the Sabbath, will, it is surmised, by those who know it, obligingly go into a state of somnolence in the winter months out of respect for the Viceroy's presence in the metropolis.

It is understood that it has been practically decided to extend the Simla drainage system by the construction of a sewer which shall serve the northern portion of the station, including the houses at the back of Jakko, Elysium Hill, Kaithu, and the Ohowra Maidan district, in the manner already adopted on the southern slope.

The Government of India has sanctioned the grant to Lady Superintendents of the Indian Nursing Service of a deputation allowance of Rs. 5 per day, for the period they are absent from their stations on inspection tours, in lieu of the present detention allowance.

The *New York Medical Record*, writes—"It is said that uneducated and unqualified persons have as much right to practice medicine in India as fully qualified practitioners, and that in the present condition of that country it is impossible to prevent the people from employing the uneducated native practitioners."

Either spray for hypertrophied spleen has proved extremely efficacious in relieving the respiration, the congestion of the organ and the pain, in twelve new observations of malarial hypertrophied spleen. The left half of the abdomen was sprayed twice a day with 25 to 30 grams ether, and in about a month the spleen was reduced to normal size.

A son of Mr. Jordan, chemist, Postcardawe, recently qualified as a chemist, and a telegram announcing the fact reached the proud father in the following terms—

Borrow vanquished;
Labour ended,
Jordan passed.

The case against Dr. Sheppard of Darjiling, the pseudo-Bombay General, was concluded on the 18th instant before the Deputy Commissioner of Darjiling. Dr. Sheppard was convicted on three charges of cheating, and sentenced to twelve months' rigorous imprisonment. He is called "doctor" but has no diploma of any kind.

Military Assistant Surgeon *Ray*, on leave from his ordinary duty, has been reappointed Medical Officer to be attached to the Eastern Bengal State Railway at Serdikh, and Military Assistant Surgeon G. E. O. Neal will be Medical Officer attached to the same Railway at Serdikh.

It is understood that Surgeon-Colonel Stephen, Sanitary Commissioner, Assam, succeeds Surgeon-Colonel Rays, as Inspector-General of Civil Hospitals, Panjak, the latter going next month on eight months' furlough, prior to retirement.

A writer in the *Medical Press* says: "It is computed that there are 26,500,000,000,000 of cells in the adult human body, of which 4,000,000,000,000 are fixed, and 22,500,000,000,000 vagrant." The cells of the nervous system are said to number 3,000,000,000.

A man dropped his wig in the street, and a body who was following close behind the loser picked it up and handed it to him. "Thanks, my boy," said the owner of the wig. "You are the first genuine hair-restorer I have ever seen."

Some eminent medical men now declare that there is no such disease as hydrophobia. They claim that it is nothing more or less than a nervous terror which takes possession of the patient, who in reality dies of pure fright.

Acetic acid injected by means of a glass syringe into all cracks and crevices of beds infested with bugs is said to be an excellent remedy against these troublesome pests, as a drop of acetic acid infallibly kills a whole nest of them.

In the Crimean War 68.5 per cent. of the amputations proved fatal. Antiseptic surgery has reduced the fatality, so that in our Civil War only 48.1 per cent. proved fatal, and in the year 1890 the mortality had been reduced to 6.9 per cent.

The warrant reconstituting the Army Medical Staff has been published in England. It is understood that the Government of India has been asked to submit proposals with regard to the Indian Medical Staff.

Dr. Cook, the Health Officer, is to be relieved of his plague duties in order that he may devote his attention specially to the conservancy of the city. Dr. Bannerman, who has had great plague experience, replaces Dr. Cook for the present.

Dr. Vanderstraeten, junior will bring forward, at the next meeting of the Ceylon branch of the British Medical Association, an important motion urging the adoption of a scheme of Medical Registration in Ceylon.

The Catholic authorities at Rome have rendered a decision forbidding the practice of artificial impregnation, derived by Sims. The reasons for this prohibition are not stated in the decree.

Mr. William Gabriel Rockwood, M.D., (Madras), has been appointed an Unofficial Member of the Legislative Council of the Island of Ceylon.

Surgeon-Captain D. M. Moir, M.B., Editor, *Indian Medical Gazette* has just married a handsome Armenian lady of Calcutta.

The Government of Western Australia has passed a law prohibiting persons suffering from contagious diseases from entering the Colony.

Surgeon-Captain O. M. Maiti, F.R.C.S., Resident Surgeon, Presidency General Hospital, Calcutta, is allowed furlough for a year, and Surgeon-Captain F. B. Ghosh is appointed to act in his place.

Drainage Tubes are used by Delezenne, made of nickel perforated throughout, with a wide rim, to prevent its escaping into the wound. A cotton wick inside absorbs the fluid like the wick of a lamp, and ensures perfect drainage.

It is understood that a Royal Warrant, dealing with the Indian Medical Service, on lines similar to those followed in the case of the Army Medical Staff, will shortly be issued at home.

Burgin-Lieut.-Col. C. H. Jonbert continues to act as Secretary to the Calcutta Martiniere and as general practitioner in the city and suburbs.

The word "microbe" was first introduced to the scientific world by M. Sedillot in a communication presented to the Academie des Science of Paris, in 1878.

Dr. V. L. Watts, Civil Medical Officer, Bogra, is appointed to be Civil Medical Officer, Bankura, but will continue to act in his present appointment.

In France, if a person dies with more debts than can be covered by his estate, the doctor's bill has precedence over all other claims.

Brigade-Surgeon-Lieutenant-Colonel Preonath Mookerjee, Civil Surgeon of Saging, has died from a carbuncle, after a lingering illness. He was very popular.

Surgeon-Colonel H. S. M. Price, Army Medical Staff, has been appointed Honorary Surgeon to the Viceroy, vice Surgeon-Colonel C. Atkins, vacated.

Dr. J. L. Hendley, Civil Medical Officer, Bankura, is appointed to be Civil Medical Officer, Puri, vice Surgeon-Lieutenant-Colonel K. P. Gupta, retired.

Cases reported as *true plague* in Calcutta continue to be eliminated as being other than plague. Hence a Nathan must arise and declare the David of Bengal to have erred.

We learn that Miss A. Church, M.B., is likely to be appointed later on in charge of the new Victoria Dufferin Hospital in Amherst Street, Calcutta.

Surgeon-Lieutenant-Colonel Backhouse, Indian Medical Service, is permitted to retire

Dr. Budin has been appointed as Tarnier's successor to the chair of Obstetrics in Paris.

Dr. Arnold Caddy of Calcutta has gone home on a brief holiday.

Dr. Charles Banks has begun private medical practice in Calcutta.

Surgeon-Major D. M. Crawford is doing excellent work in the South Suburban Hospital, Calcutta.

We regret to announce the death of Surgeon-Lieutenant H. E. Miles, I.S.M.D., of Bright's disease on the 30th July.

The Medical Register and Directory of the Indian Empire is now ready and is issuing to all registered subscribers. No time should be lost to secure copies.

Current Medical Literature.

MEDICINE.

Alcohol as a causative factor in disease of the Central nervous system.

In the general outline of the facts concerning alcohol as a factor in central nerve disease, Dr. T. D. CHOTKIN, points out (1) That alcohol is a poison of the narcotic class which acting on the body psychologically, physiologically and pathologically is, next to syphilis the most frequent cause of diseases of the brain and has so profoundly distinctive an action on waste and repair that it predisposes to many diseases by becoming a literal paralysis and dislocation that enflees all the powers of life and lowers their power of resistance. (2) It seems to have a special toxic action on the peripheral nerves stimulating them at first then accentuating them, then over-exciting them after which they are depressed, their activity perverted and the power of restoration from nutrition destroyed. (3) The apparent recovery from the narcotism of single-drunk paroxysm is never real as the convulsive discharge of nerve energy, through its influence, permanently deranges the dynamic equilibrium of the nerve centres and its repetition now only fixes this condition, but also so lessens the power of resistance to disease that local inflammations from infections, injuries, strains or drains can not be overcome and death closes the chapter of woes. (4) Alcohol disturbing the functional processes and diminishing the sensory activities induces a general psychical paralysis beginning with the ego, blunting or obscuring the moral and ethical senses, inducing insomnia, melancholy suspicion and various delusions, changing the emotional states and extending to all parts of the body ends in muscular depression and mental enfeeblement. (5) Periodic drinking is a convulsive disease like epilepsy and belongs to the same family group. (6) Alcohol both releases and concentrates nerve energy. The increased and diminished vascular actions with diminished sensory power point to profound disturbance of the dynamic forces of the brain in which there is a continuous gathering and discharge of nerve energy. This is increased, retarded and perverted by drugs, food and environments and the change of this nerve energy is seen in the functional disturbances of the body which are very prominent in early and in late life. —*Jour. Amer. Med. Assoc.*

Blood Reaction in Diabetes.

LOWRY records some further investigations of BÄRMER's reaction in the blood of diabetic patients. The original method of obtaining the reaction was to stain a film of blood in two solutions, each consisting of a mixture of 0.5 per cent. solution of eosin with a saturated solution of methylene blue, the one contained excess of the former, the other excess of the latter stain. After passing the film through these two mixtures successively, BÄRMER found that in normal blood the red corpuscles were stained deep brown, whereas in diabetic blood they are left pale yellow or greenish yellow. LOWRY, in his experiments, used the simpler modification which has lately been suggested. The blood is stained two minutes in 2 per cent. methylene blue, and then 10 seconds 0.125 per cent. eosin solution. Keeping strictly to the technique described by BÄRMER in this method, LOWRY found that in every case of diabetes in which the amount of sugar in the urine was more than 2 per cent., the blood gave the characteristic reaction. In one case, where dieting had already caused the sugar to disappear, the reaction was still obtained in the blood. The failure of several observers to obtain the reaction in diabetes is probably due to their not

of appointment to the medical charge of civil stations, the Government of India considered the claims of Civil Assistant Surgeons inferior to those of Military Assistant Surgeons. We are entirely at a loss to understand the reasons which led the Government of India to come to this decision. Are Military Assistant Surgeons superior in the matter of professional qualifications? We hope this question will be answered by Dr. HANVY, the present Director-General of the Indian Medical Service. As he served for many years as a Professor to Civil Assistant Surgeons in the Calcutta Medical College, his opinion on this subject will carry more weight with the public than that of Dr. CLEGG, who does not possess this special knowledge and experience required for arriving at a correct judgment on this important point.

The views of Local Governments and Administrations upon the questions referred to them having been received, the Government of India have issued final orders on the subject. They have sanctioned the creation of a senior grade of Civil Assistant Surgeons on a salary of Rs. 300 a month. The number of Senior Assistant Surgeons in each Province must not however exceed 10 per cent. of the total strength of the service in the Province, excluding the Assistant Surgeons who may be permanently appointed to the charge of civil stations. The question whether the full number of Senior Assistant Surgeons should be appointed at once is left to the discretion of the Local Government and the Inspector of Civil Hospitals; but it is directed that only thoroughly competent officers should be appointed. Promotion from the first grade on Rs. 200 to the senior grade will be made entirely by selection and without examination. This provision, we are inclined to think, will lead to the exercise of favouritism on the part of the Inspector General of Civil Hospitals. The Bengal Committee had recommended that an increase should be granted to Civil Assistant Surgeons at the end of 21 years' service, subject to a professional examination; but the Government of India have decided not to accept this proposal. Promotion from the grades on Rs. 100 and Rs. 150, respectively, will, as hitherto, depend on the results of septennial examinations. But Assistant Surgeons, who are not now in service, will not be permitted to appear at the second examination as a matter of course. They will not be allowed to do so unless they are considered fit for promotion by the Inspector-General of Civil Hospitals. It will thus be seen that the position of Civil Assistant Surgeons has been actually made worse under the new scheme than it is now. The rule that future entrants into the service will not be permitted to appear at the second examination as a matter of course will operate as a great hardship. It is to be earnestly hoped that the Government of India will reconsider this matter. The creation of a limited number of senior Assistant Surgeons will not make up for the loss caused by depriving future entrants into the service of the right of appearing at the second examination. As regards the reservations of a certain number of civil stations for Civil Assistant Surgeons, the Government of India have sanctioned the reservation of 19 Civil Surgeoncies for this class of officers—namely, 5 in Madras, 2 in Bombay, 5 in Bengal, 2 in the United Provinces, 3 in the Punjab and 2 in Burma. This number is quite inadequate to do

justice to the vast claims of Civil Assistant Surgeons, who should, in this respect, be at least placed on a footing of equality with Military Assistant Surgeons. The new scheme for improving the conditions of service of Civil Assistant Surgeons will greatly disappoint them. If the Government of India are sincerely desirous of bettering the position and prospects of this useful class of officers, they should raise the pay of each of the three grades at present existing by Rs. 50 a month. Such a general increase of pay would in some measure ameliorate the position and prospects of Civil Assistant Surgeons and make the service more attractive."

Yours &c., ASSISTANT SURGEON.

—:O:—

CIVIL APOTHECARIES AND THEIR GRIEVANCES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Through the great interest taken by you and by the Indian Medical Association, I am glad to note that the Civil Assistant Surgeons have at last had some of their grievances redressed, inasmuch as their pay and future prospects have been bettered. I however regret to state, that nothing has yet been done for the unfortunate Civil Apothecaries, although in your issue of the 16th April 1896 (in which appeared a letter putting forth the grievances of the Civil Apothecaries) you were kind enough to note that the grievances of this class are "very real and must be embodied in the next representation to Government from the Indian Medical Association." "I am sure a number of Civil Apothecaries who are subscribers to your journal and also members of the I. M. A. fully expected that something would at last have been done for them—but we have all been doomed to disappointment, since the question has not at any time been taken up by the Association.

As has already been pointed out in the letter that appeared in the I. M. R. of the 16th April 1896, the class of Civil Apothecaries serves the same purpose as the class of Assistant Surgeons does in other Presidencies. The course of study—as also noted by you in your latest Directory—was, and is the same as that for the L.M.S. which is the qualification of the present Civil Assistant Surgeon grade of the Madras Presidency. It is a known fact that most of the students of the Apothecary class have shown themselves superior in attainments and qualifications to those of the L. M. and S. class; and several Presidency and District Surgeons could also testify to the abilities of this class after their leaving College. The only difference between the present Civil Assistant Surgeon grade and the Civil Apothecary grade, is, that the former appear for the university test and the latter for the test prescribed by Government. The Civil Apothecary is found qualified to do exactly what the Civil Assistant Surgeon is required to do; but in designation and salary there is a marked and unfortunate difference. Even in the scale of fees set down by Government for private practice and travelling no difference whatever has been made between the two classes. I therefore beg to request that "better late—than never"—the Indian Medical Association will be kind enough to advocate the cause of the Civil Apothecaries and obtain some redress for their wrongs.

In the notification of the Government of India dated August 27th 1898, certain important concessions were made to the Civil Assistant Surgeons. In the latter part of this notification it is stated that the new arrangement comes into force at once except in Madras and Bombay, where steps are to be taken to gradually assimilate the pay and position of Assistant Surgeons to the General scheme. This may perhaps mean that as the present strength of the Madras Civil Assistant Surgeon grade is only 25, the Civil Apothecary class will be absorbed with the Civil Assistant Surgeon class, as was sometime ago proposed by the Surgeon General with the Government of Madras. This could be very easily done, and the number of Assistant Surgeons would be raised to the proportionate strength of the other Presidencies. Unless this be done, the proportion of Civil Surgeoncies reserved for Madras according to the notification alluded to, will be far in excess of that for Bengal and Bombay, since five Civil Surgeoncies would be reserved for only 25 men.

You have in your valuable journal ably advocated the wrongs of the various classes of Military and Civil Assistant Surgeons and Hospital Assistants, and obtained some redress for their grievances: and you will now I trust be kind enough to espouse the cause of the hard-worked and badly paid C. A. class. And you will thereby earn the gratitude of no less than 142 unfortunate Civil Apothecaries whom nobody seems to think of, or take any interest in. In conclusion let me add that I hope the Indian Medical Association will, after due consideration, obtain for the Civil Apothecary class what is, and should be its by right.

Thanking you in anticipation for the kind interest you will, I know, take in our cause.

Yours &c., A CIVIL APOTHECARY OF MORE THAN
14 YEARS' SERVICE.

(If our correspondent will kindly refer to our remarks on this subject he will find that we asked for full information concerning this class of medical officers. It has not been forthcoming. If some representative of this class will detail the points of their grievances in the Record, something can be done.—ED., I. M. R.)

—:o:—

WHO DOES THE JOBS?

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR—I beg to bring to your notice, for the information of the Principal Medical Officer, Her Majesty's Forces in India, through the medium of your valuable paper, a few facts relating to jobbery and favouritism in the Indian Subordinate Medical Department. Although second, and first class Assistant Surgeons are really available, of good conduct, for the Subordinate charge of Rest Camps in the various Districts where Rest Camps are allowed, still owing no doubt to favouritism, and perhaps to what the Indian calls "*salami*" to the Head Clerks of the District Offices, this year 3rd Class Assistant Surgeons are being appointed for duty in the Rest Camps; now Sir this is not fair play to their seniors, as the post is really one for 1st or 2nd Class Assistant Surgeons and surely length of honourable service should entitle a man to some claim over a junior. The posts hold the allowance of Rs. 30 per month and a junior is not really entitled to it, this is proved by the fact that a junior when in charge draws also an acting allowance of 25 Rupees a month (as he is doing the duties of a 2nd Class man) thus a Junior gets 55

Rupees a month extra and a senior although available for the duty is robbed either for a short time, or for the whole period of an allowance to which he is legally entitled by right of seniority "*Oh Favouritism, thy name is Justice*"! The Government is also robbed by this arrangement Sir, because with a 3rd class man drawing 2nd Class pay and allowances and a senior available for the duty—

Government pays the senior	85	Rs. per month.
and the Junior	115	Rs. do

Total	200	Rs. per month
-------	-----	---------------

the other way with the senior doing his legal duty, and drawing his legal allowance—

the Senior draws	115	Rs. per month
and the Junior draws	60	Rs. "

Total	175	Rs. "
-------	-----	-------

a saving on the face of it, of Rupees 25 a month to Government, and the P. M. O's of districts are supposed to save money for Government if possible, are they not? I wonder the Pay Department do not see though these official jobberies and take it up for the Government on the score of economy and justice to the Labourer. This is being done in two or three districts in the Bengal Command, and the Government and the tax-payer are losing by it. It is useless for the seniors to complain unless they have long purses. Hoping you will publish this,

Yours &c., FAIR PLAY.

—:o:—

OLD AND NEW TITLES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In my letter in your last issue, I would not be taken to oppose the legitimate alteration in the titles of our commissioned grades, necessitated by the changes in the I. M. S. consequent upon this New Warrant for the R. A. M. Corps.

No! coincident with the recognition of the composite titles as an objectionable anomaly for all Commissioned Officers, ours must needs share in the changes as a matter of course, unless indeed, it is intended to accentuate and ridicule their already sufficiently questionable status. Hence I considered it unnecessary to touch upon the subject in my letter of remonstrance.

I only protested against the substitution of one *departmental designation*, as distinguished from *military rank* for another, on the assumption that it was merely a logical extension of the principle involved in the new Royal Warrant, of course I am now referring to the non-commissioned grades.

I would be clear. Let the Departmental designations of "Assistant Surgeon and Senior Assistant Surgeon" stand. Merely alter the composite titles in the commissioned grades to correspond with those of the R. A. M. Corps and our own service "the I. M. S."

Yours &c., "AN OLD ASSISTANT SURGEON."

—:o:—

MILITARY ASSISTANT SURGEONS, ANOTHER PROTEST.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I was more than pleased to read in the last edition of your valued paper the comments of "an old Assistant

Surgeon," I am sure he voices the opinion of the whole service, when he truly points out that if the suggestions put forward by "P" in your journal, dated 16th ultimo, be asked for and granted, it would be a decided retrograde movement. Personally I should consider that I had lost much if I had to affix the term "Sub-conductor" or "Conductor" after my name in place of the designation which indicates the noble profession to which I belong. I feel confident that the Indian Medical Association will not submit any such foolish proposal to the Government. I feel sure "P" does not belong to "our ilk" or such an absurd proposal would never have been penned. I feel confident also that "P's" views will not meet with support from the Service, on the contrary he will have to peruse many adverse criticisms on his wild schemes.

Yours &c., ASSISTANT SURGEON NOT CONDUCTOR.

—:—

THE C. D. ACTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—A medical man asks me to withdraw my reference to his error (1) regarding the number of the ladies who signed the memorial on the C. D. Acts. I am far from my station, but I think, he himself obtained his information from the *British Medical Journal*. He had better write to that Journal and set things right. I found lately in another paper the number put down at 85 so I will wait. Meanwhile I am waiting until "a medical man" answers the letter and complies with the request of your non-medical reader, and give us a synethetical statement of the case, a constructive defence of the C. D. regulations and perhaps he will be able to give a sound defence of the action of Government in no longer carrying on these regulations *openly* and above board in Lock Hospitals but in *Cantonment* Hospitals. It will take all the arguments he can bring to convince impartial witnesses, that they are not trying to throw dust in the eyes of folks here and in Britain, while at the same time they are inflicting an injury on the natives of the Cantonment by charging on the local funds the extra outlay demanded by this new arrangement for *Imperial* purposes. I hope "a medical man" will carefully answer "non-medical's" letter soon. I am waiting to be edified as well.

Yours &c., W. HUNTLY, M.A. M.D., R.S.O.
NUSSERABAD.

—:—

WANTED TREATMENT AND OPINION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you please let me know the best mode of treatment to be adopted in case of a burn of the whole arm, that is after the healing process has been completed. Opinion is especially required in regard to prevent the contraction that takes place at the elbow, and as to how the fingers are to be flexed when stiff. How soon after can liniment friction be used?

Yours &c., MEDICUS.

THE EDEN SANITARIUM, DARJEELING.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—A movement is on foot in Darjeeling to convert the Eden Sanitarium into a real hospital. At present and for years past, the objects of this institution are being and have been much abused. It is simply utilised as a hotel, and in this way it has not only done harm to the interests of a well deserving class of public caterers (boarding house keepers) who have been practically ruined by the competition of the Eden Sanitarium, but the influx into its wards of men and women in obviously good health has tended to rob really sick people of the advantages of a change under medical supervision. It is very pleasing to note that the present Civil Surgeon, Dr. LEWIS, who has made himself a *persona grata* with the residents of Darjeeling by his kind and skilful treatment, is in favour of abolishing the hotel element of the Sanitarium, and its conversion into a hospital, pure and simple. We hope the *Record* will support this suggested alteration.

Yours &c., DARJEELING DOCTOR.

(We have in our columns frequently exposed the objectionable phase of hotel competition which the Sanitarium has so long assumed, and we earnestly hope that Surgeon Lieutenant-Colonel J. Lewis will use his influential efforts to bring about this much needed change for the public good.—Ed., I.M.R.)

—:—

COLLEGE FEES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I shall feel obliged if you or any of the readers of your Journal will kindly inform me through its columns, what the fees are that a Military Assistant Surgeon, Bengal, has to pay to procure the necessary certificates of lectures attended and courses taken by him in the Medical College, Calcutta, to enable him to appear for an English degree.

Yours &c. "ONE INTERESTED."

Book Reviews.

OFFICIAL YEAR BOOK OF THE SCIENTIFIC AND LEARNED SOCIETIES OF GREAT BRITAIN AND IRELAND.

(Publishers: CHARLES GRIFFIN, and Co. Ltd., London, Price 7s. 6d. pages 281).

THE present, which is the fifteenth annual issue, fully maintains the excellent standard reached by its predecessors. A chronicle is given of the work done during the year by the several Scientific and Learned Societies at Home in the various departments. This publication which may well be regarded as a Record of Progress in every sense of the term, will be found to be a most convenient hand book of reference.

THE STORY OF THE MALAKAND FIELD FORCE, AN EPISODE OF THE FRONTIER WAR.

BY W. L. S. CHURCHILL, LIEUTENANT, R.O.M.

(Longman's Colonial Library, pages 336, with Maps, Plans, &c.)

WE are here furnished with a very handy, concise, and interesting narrative of the Campaign of 1897 whose principle events are no doubt still fresh in the recollec-

tions of our readers. Its value is increased by the circumstance that the Appendices include the text of the military despatches with the official records of approval &c., while an excellent portrait of Major-General Sir Bindon BLOOD, K.C.B., who commanded the Malakand Field Force, precedes the work.

THE DOCTRINE OF ENERGY, A THEORY OF REALITY.

By B. L. L.

(Publishers:—Messrs. Kegan Paul, Trench, Trubner and Co. Ltd., London. Price 2s. 6d. pages 108.)

An effort has been made in this brochure towards substantiating the theory that the conception of energy, recently postulated on behalf of Physical Science, really embraces and supersedes the conception of matter, and by itself adequately explains the real element in all physical phenomena. The attempt made to prove this original theory is as clever as it is bold, and will repay perusal by persons with a taste for metaphysics.

A TREATISE ON APHASIA AND OTHER SPEECH DEFECTS.

By H. CHARLTON BASTIAN, M.A., M.D., F.R.S.

Emeritus Professor of Medicine in University College, London, &c., &c.

(Publisher: H. K. Lewis, London, pages 366, Price 15s.)

This work treats in a more ambitious and exhaustive manner than has hitherto been attempted, the subject of the various defects of speech. The complete, if somewhat lengthy, views of the author are supported by a large number of typical cases which have come under his own experience. The book is certain to prove exceedingly valuable to medical men and others interested in the subject with which it deals.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Hosp. Asst. Desu Ram made over, 1st Aug. 1898, the medical charge of the Detachment, Brinapura Irregular Force at Abu, to Hosp. Asst. Rampershad Banerji, Rajputana Agency Hosp.

Surgn.-Col. A. Stephen, M.B., I. M. S., (Bengal), Principal Med. Officer and Sany. Commr. Assam Dist., to officiate as Insptr.-Genl. of Civil Hosps. Farakka.

Asst. Surgn. Guildford Thoy to be second-class Asst. Surgn. from 14th May 1898.

Asst. Surgn. Herbert Edward Benson to be second-class Asst. Surgn. from 7th June 1898.

To be Surgn.-Col. Brig. Surgn.-Lt. Col. Arthur Mudge Branfoot, 1st March 1898.

To be Brig.-Surgn.-Lieut.-Col. Surgn.-Lieut.-Col. Arthur Henry Cold Dand, M.D., 1st April 1898.

To be Senior Asst. Surgn. with hon. rank of Surgn.-Capt. George William Bate, 21st Sept. 1897.

To be Senior Asst. Surgn. with hon. rank of Surgn.-Lieut. Henry Herbert Miles, 21st Sept. 1897.

Asst. Surgn. Julius Brown to be Senior Asst. Surgn. with hon. rank of Surgn.-Lieut.

Asst. Surgn. William F. O'Connor to be Senior Asst. Surgn. with hon. rank of Surgn.-Lieut.

To be Senior Asst. Surgn. first class James Halpin, Thomas Baldry, Arthur Willoughby Woodward Sadler, Eugene Alfred St. Romaine, William Christopher Montague Charters, and James Adolphus Fanshaw Harvey, from 8th Dec. 1898.

To be Asst. Surgn. Henry Desmond Bazely, Frederick William Mathews, Herbert Charles Thompson.

To be Brig. Surgn. Lieut.-Col. Surgn.-Lieut.-Col. John Philip Greany, M.D., 9th June 1898.

Third class Asst. Surgn. Alexander Douglas Cunningham Perdrin to be second-class Asst. Surgn. from 29th Jan. 1898.

Senior Asst. Surgn. and Hon. Surgn.-Lieut. Richard Michael Blaker to be Senior Asst. Surgn. with hon. rank of Surgn.-Capt.

Asst. Surgn. Isaac Burnett to be Senior Asst. Surgn. with hon. rank of Surgn.-Lieut.

Second class Asst. Surgn. William David Busher to be first-class Asst. Surgn., third-class Asst.-Surgn. Arthur George Culpeper to be second class Asst. Surgn. from 17th Feb. 1898.

BENGAL GOVERNMENT.

The services of Surgn.-Major W. B. Bannerman are replaced at the disposal of the Govt. of India, Home Dept.

The services of Surgn.-Capt. B. H. Deare, Offg. Civil Surgn. of Midnapore, are placed temp. at the disposal of the Chairman of the Corporation of Calcutta.

Dr. J. A. Fink, Offg. Civil Med. Officer of Bhagalpur, to act as Civil Med. Officer of Midnapore.

Asst. Surgn. Ambica Charan Datta to act as 2nd Demonstrator of Anatomy, Med. College Hosp., Calcutta.

Asst. Surgn. Benode Bihary Ghosal, to temp. med. charge, Tangail subdn., Mymensingh.

Asst. Surgn. Bharat Chandra Dhar, Tangail subdn., leave for three months.

Asst. Surgn. Mohendra Nath Das, to Jessore Diapy.

Asst. Surgn. Upendra Narain Roy, Jessore Diapy. to the diapy. in the Tributary State of Dhenkanal.

The following Civil Hosp. Assts. passed the medico-legal examination of Med. Sub. 30th June 1898, Gokul Chander Chatterjee, Mohit Chunder Ghose, Raj Mohun Bonick, Nibarun Chunder Ukila, Jagabandhu Gupta.

Asst. Surgn. Brojo Nath Shaha, Civil Eng. College, Sibpur leave for two months.

Asst. Surgn. Kasi Nath Ghosh, to do duty Civil Eng. College, Sibpur.

Asst. Surgn. Mohendro Nath Dutt did supery. duty, Med. College Hosp. Calcutta, from 29th July to 5th Aug. 1898.

The services of Surgn.-Capt. U B. M. Green, Offg. Civil Surgn. of Howrah, are placed temp. at the disposal of the Chairman of the Corporation of Calcutta.

Surgn. Capt. E. H. Brown, Civil Surgn. of Purnea, to act as Civil Surgn. of Howrah.

Dr. J. A. Fink Offg. Civil Med. Officer, of Bhagalpur to act as Civil Med. Officer of Purnea.

Surgn.-Capt. J. C. S. Vaughan, Depy. Sany. Commr., to act as Civil Surgeon of Bardwan.

Asst. Surgn. Gopal Chander Mukherjee to act as Depy. Sany. Commr. also on special duty in connection with anti-cholera inoculation.

Asst. Surgn. F. J. Daley did duty at the Presy. Genl. Hosp., Calcutta, from 4th to 10th June 1898.

PUNJAB GOVERNMENT.

Surgn.-Col. A. Stephens, M.B., B. Sc. (Bengal), Prin. Med. Officer and Surg. Commr. Amritsar Dist. to officiate as Inspcr.-Genl. of Civil Hosps., Panjab.

The services of Hosp. Asst. Hovea Das being no longer required for special plague duty in the Jullundur dist., he reverted to Shabkadar Dispy. Ferozepur dist. 23rd Aug. 1898.

Hosp. Asst. Sahib Ditta Mal, one month's privilege leave from 25th June 1898.

Hosp. Asst. Sahib Ditta Mal was placed on genl. duty, Jullundur, from 25th July 1898.

The services of Hosp., Asst. Karm Chand being no longer required for special plague duty, Hoshiarpur dist., he was re-apptd. to Garhshankar Dispy, same dist. 25th July, 1898.

The services of Hosp. Asst. Tulsi Ram being no longer required for special plague duty, Jullundur dist., he reported himself to the Civil Surgn., Amritsar, for genl. duty 22nd Aug. 1898.

Hosp. Asst. Gurmukh Rai, Feroza Dispy. Karnal dist., three months' privilege leave, from 26th Aug 1898.

Hosp. Asst. Sukhraj Das, to City Branch Dispy, Sialkot, 22nd Aug. 1898.

Hosp. Asst. Ghulam Hussain was placed on genl. duty at Ludhiana, from 27th Aug 1898.

Hosp. Asst. Gurmukh Singh having passed the English Qual. Exams. entitled to the higher rate of pay of his grade, from 2nd July 1898.

Hosp. Assts. Brij Lal, Hari Singh, Wali Muhammad, Labha Mal, Devi Dial, were placed on genl. duty, Mayo Hosp Lahore, from 27th Aug. 1898.

CENTRAL PROVINCES GOVERNMENT

Mr. Thomas W. Quinn is confirmed in his appt in the U. M. S., and his services are placed at the disposal of the Chief Commr from 17th July 1898.

Civil Hosp Asst Bahram, Ramkrishna Lal, Ramchandra Sitaram to do duty under Civil Surgn of Nagpur.

One month's privilege leave is granted to Hosp Asst., Lakshman Bapuji, Itwari Branch Dispy., from 21st Aug 1898.

Hosp. Asst. Narain Vinayak, Jail Hosp., Bilaspur, to do duty under Civil Surgn, Bilaspur.

Hosp. Asst. Ramkrishna Lal, doing duty under Civil Surgn, Nagpur, is tempy. posted to the Itwari Dispy.

N. W. P. AND OUDH GOVERNMENT.

Surgn Capt. J. Garvie, Offg Civil Surgn. Sitapur, privilege leave for two months.

Asst. Surgn. Prakash Chandra Mukerji, Sagar Dispy. Allahabad, privilege leave for 8 months, from 24th Sept. 1898.

Asst. Surgn Gopal Chandra Gupta, to Secunderabad Dispy., Bulandshahr.

Asst. Surgn. Chanan Singh, on Reserve duty at Agra, to Sagar Dispy. Allahabad.

Hosp., Asst. Nazir-ud-din, Police Hospital, Meerut, is promoted to 1st grade, 14th April 1898.

BURMA GOVERNMENT.

B. A. Hollingsworth, L. G. Fink, and H. J. Augustine, are confirmed in their appts. in the U. M. S., and their services are placed permanently at the disposal of the Govt. of Burma, from 15th March, 24th June, and 11th July 1894, respectively.

Mr. C. Martin made over, and Asst. Surgn. W. St. M. McErmann assumed charge, Civil Surgency, Mogaung subdv. Myittha dist., 30th Aug. 1898.

Asst. Surgn. San O. Po made over, and Asst. Surgn P. McCarthy assumed charge Civil Surgency, Kyaukse dist., 17th Aug. 1898.

Asst. Surgn San O. Po assumed charge Civil Hospl., Bassein, 26th Aug. 1898.

Hospl. Asst. Ghulam Mustafa, assumed charge Civil Hospl. Lashio, Northern Shan States, as a supery., 27th June 1898.

Hospl. Asst. Ghulam Mustafa, assumed charge of duties with the Mily. Police escort proceeding to Tawlio, Northern Shan States.

Hosp. Asst. Ghulam Mustafa, assumed charge Outpost hosp. Tawlio, Northern Shan States.

Hosp. Asst. Wasir Singh, assumed charge Civil Dap., Kengtung, Southern Shan States, 4th Aug. 1898.

Hosp. Asst. Shaik Abdul Rahman, assumed charge Civil Hosp. Pagan, Myingyan dist 21st Aug 1898.

Hosp. Asst. Shaik Abdul Bahaman, assumed charge Mily. Police Hosp. Pagan, Myingyan dist, 21st Aug 1898.

Hosp. Asst. Hem Chandra Koyal assumed charge Genl. Hosp., Akyab, 20th Aug 1898.

Hosp. Asst. Bam Chander Paddar assumed charge Civil Hosp. Paungbyin, 17th July 1898.

Hosp. Asst. Sunder Singh, assumed charge Civil Hosp Letpadan, Tharrawaddy dist. 22nd Aug 1898.

Hosp. Asst. T. V. Annandam Nambiar assumed charge Mily. Police Hosp. Pakokku, 25th Aug 1898.

Hosp. Asst. P. Devanraja Pillay assumed charge Mily. Police Hosp. Bhamo, 20th Aug, 1898.

Hosp. Asst. Gajan Singh, relinquished charge Mily, Police, Hosp. Bhamo, 20th Aug. 1898.

Hosp. Asst. Chowdhury Sharfuddin assumed charge Civil Hosp., Minha, Thayetmyo dist., 18th Aug. 1898.

Hosp Asst Chowdhry Maula Bukah assumed charge Civil Hosp. Victoria Point, Mergui dist 31st July 1898.

Hosp. Asst. S. Muniratra Pillay assumed charge Outpost Hosp Fort White, Chin Hills, 21st July 1898.

Hosp. Asst. H. Mangesa Rao, assumed charge Jail Hosp. Yamethin, 11th Augt 1898.

Hosp Asst. M. Henry Peter, assumed charge Mily. Police Hosp. Mogaung, 12th Augt 1898.

Hosp. Asst. Babu Saraswati Dutta Misra assumed charge Mily. Police Hosp Mandalay, 19th Augt. 1898.

Hosp Asst. T. J. Govindaswamy Pillay, assumed charge Civil Hosp. Myingyan, 22nd Augt. 1898.

Hosp. Asst. T. J. Govindaswamy Pillay, held charge Police Hosp. Pagan, Myingyan dist from 6th 21st Augt. 1898.

Hosp. Asst. T. J. Govindaswamy Pillay, relieved. charge Civil Hosp. Myingyan, 25th Augt. 1898.

Hosp. Asst. S. Bastian was attached as a supy to Civil Hosp. Myingyan from 22nd Augt. 1898, to 25th Augt. 1898.

Hosp. Asst. S. Bastian was assumed charge Civil Hosp. Myingyan, 25th Augt. 1898.

Hosp. Asst. Dhanaswar Panda, assumed charge as a supy. at the Civil Hosp Lashio, Northern Shan States, 21st May 1898.

Hosp. Asst. Dhanaswar Panda assumed charge Mily. Police Hosp. Kutkal, Northern Shan States, 24th June 1898.

G. O. C. C.

Col. R. de la C. Corbett, M.D., D.S.O., to be Prin. Med. Officer, Oudh and Rohilkhand dist.

Brig.-Surgn.-Lieut.-Col. C. W. Carr-Oliphant, M.D., to officiate as Principal Med. Officer, Assam dist.

Asst. Surgeon, George Edward Shaw, George Patrick O'Brien Edward Archer, having passed their dept. exam. are entitled to the enhanced rate of pay of their class.

John Bajaratsam, and Muhammad Abdul Asim Khan, having passed their final exam. are admitted into the service as Sub-Hosp. Assts. from 30th June, 1898.

ASSAM; GOVERNMENT.

Munshi Abdul Aziz, a passed student Dacca Med. School, is apptd. on probation for six months, a Civil Hosp. Asst. in Assam, and is posted to Tezpur for duty as a Supy., from 23rd Aug. 1898.

Hosp. Asst. Rosh Mohan Chakravarti, a Supy., Khasi and Jaintia Hills dist., to Sylhet dist., and apptd. a Supy., for duty under Civil Surgeon, from 21st July 1898.

Sick leave for two months, is granted to Hosp. Asst. Sati Kanta Sen, Chittagong Dist., Sylhet dist., from 20th Aug. 1898.

Hosp. Asst. Rosh Mohan Chakravarti, a Supy., Sylhet dist., to Chittagong Dist., from 19th Aug. 1898.

Babu Rajani Kanta Manlik, a passed student, Dacca Med. School, is apptd. on probation for six months, a Civil Hosp. Asst. in Assam, and is posted to Sibschar, Cachar dist., for duty as a Supy., from 27th Aug. 1898.

Babu Narendra Nath Datta, a passed student, Dacca Med. School, is apptd. on probation for six months, a Civil Hosp. Asst. in Assam, and is posted to Dhubri, Goalpara dist., for duty as a Supy., from 30th Aug. 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

GARVIE.—On the 15th August, 1898, at Naini Tal, the wife of Surgeon-Captain J. Garvie, I. M. S., of a son.

DEATH.

SEMPLE.—On the 31st August, 1898, at Kasauli, Punjab, of Enteric fever, Marion Ethelwyn, the dearly loved wife of Major J. Semple R.A.M.C.

NOTICES TO CORRESPONDENTS.

T. H. A. (Shelapur).—We regret the omission you mention. The information given us officially was not complete. We have now applied to Government to supply this want.

Civil Assistant Surgeon.—You suggest with regard to the questionable "improvements" just made in your service, that the Government should change your designation to that of Surgeon, that the promised 19 Civil Surgeoncies should be made available at once, and that the 300 Rs. grade should be attainable by seniority and examination. You complain that under present arrangements the so called improvements are mere "castles in the air." The Council of the Indian Medical Association have already taken note of the remarkable *Gazette* notification which you refer to, and they will make a further representation to Government if the orders made in it are not carried out.

A. W.—Many thanks.

E. V. N. (Poona).—Writes with reference to the promotion list of the Indian Subordinate Medical Department for Field Service in the N. W. F. War; "I find that the names of Madras and Bombay Subordinates are conspicuous by their absence. Can you or any of your readers inform me of the cause, as I am confident several Bombay hands were highly recommended for this distinction."

R. E. W. (Landour).—You have our best thanks for your further contributions.

J. H. (Madras).—Your paper will appear in our next number.

H. K. M. (Bombay).—Private practitioners are at liberty if they are not in good circumstances to obtain the *Record* for Rs. 9 instead of Rs. 18, Hospital Assistants who enter private practice on leaving the service are subject to these terms.

J. W. P. (Chattrapur).—Next number.

One Interested writes:—"I note among the promotions for field service on the North West Frontier in the Indian Subordinate Medical Department, that not a Subordinate of the Madras or Bombay Establishment has been promoted, though I am informed several were recommended. Can you or any of your numerous readers enlighten those interested as to the cause of this omission." If our correspondent will send the details of his experience of the grievance he and his comrades have suffered, for publication in the *Record*, we shall be glad to give him space.

J. P. M. (Sampgaon).—Join the Indian Medical Association without delay, you will then be in a position to claim consideration.

W. H. T. (Karachi).—Many thanks. We are waiting for a few more names before publishing another list.

H. W. D.—Stick to the service for a while. We know many are disgusted with the I. S. M. D. but we feel sure the Government will soon make improvements in the department.

Dr. J. PRENTIE writes:—"I should feel much obliged for information as to the source from which you obtained the small paragraph at head of first column in page 205 of your issue, dated 1st September 1898.

I am the Civil Surgeon of Bhandara and I have not ordered a military outfit from Ranken & Co., or any other firm." The paragraph referred to, mentions the name of Major Tomkins, L. S. A. London.

S. B. H. (Surat).—Refer to the current Medical Literature section of the *Record* in its back numbers 1895-1896, and you will get all the information you require.

S. A. K. (Tharrawady).—Refer to the latest Edition of the Medical Register and Directory of the Indian Empire.

ORIGINAL ARTICLES.

DISORDERS OF THE LIVER IN TROPICAL CLIMATES.

BY SURGEON MAJOR R. E. WHARTER.

Bengal Medical Service, (Retired), Dehra Dun.

THE disordered function of the great secreting organ, the liver, gives rise to many ailments, which, more generally than perhaps consistently, are in the popular acceptation ranged under the head of bile, a fluid necessary to digestion, which also promotes the passage of the feces through the alimentary canal. What is meant by these several terms is, that the affections indicated are to be attributed to an increase, diminution, or alteration in the secretion of bile by the liver. Bile is a peculiar bitter fluid, of a yellow or greenish colour, which, when secreted by the liver, either passes directly through the hepatic duct into the upper part of the bowels, or, remaining for a time in the gall-bladder, a small membranous receptacle or pouch, of a pyriform shape, situated at the inferior and concave surface of the liver, to which it is attached and above the colon, thence passes by the cystic duct into that portion of the small intestine termed duodenum. It is said by some anatomists that the gall-bladder is not met with in all animals. It is wanting in the elephant, horse, stag, rhinoceros, and goat; in certain of the cetacea (an animal of the whale kind), in some birds, as the ostrich, pigeon, and parrot; and is occasionally deficient in man (?). Its largest part or fundus is turned forwards; and when filled, frequently projects beyond the anterior margin of the liver. Its narrowest portion, cervix, or neck is turned backwards, and terminates in the cystic duct, externally it is partly covered by the peritoneum, which attaches it to the liver, and to which it is, moreover, adherent by cellular tissue and vessels. Internally, it is rugous; the folds being reticulated, and appearing somewhat like the cells of a honey-comb.

Most disorders of the liver are recognized by an uneasy, dull, heavy, aching sensation in the right side, a pain at the top of the right shoulder, loss of appetite, sluggishness of the bowels, occasionally diarrhoea or dysentery and great general weakness. If not early attended to, these symptoms are sooner or later followed by others more serious, when medical aid is indispensably necessary. The application of a mustard leaf, superior to the old fashioned mustard poultice, or a turpentine fomentation, and a couple of Compound Rhubarb pills, or one or two Cascara Sagrada tablets at bed time with light and easily digestible diet and no alcoholic drink taken, unless there is great prostration of strength, may, and very often will, remove all the above symptoms. Torpidity of the liver is so very frequently caused by sedentary habits, that often nothing further is required to remedy it beyond good, active systematic exercise. If Europeans in India were only to take more active exercise, (but whatever exercise is taken, it should not be sufficient to induce exhaustion or fatigue), but less animal food, and be more temperate in the use of alcoholic beverages, the risk of suffering from liver disease would be materially diminished. Indeed, it may be safely asserted, that a very large, if

not the larger, number of those who suffer from "liver", owe their diseases more to their own imprudent habits, than to the climate, pure and simple. That form of headache to which the term liver, or bilious headache is applied, though often connected with, alteration of the hepatic function, is also frequently dependent on disorder of the stomach. It is characterized by a dull, heavy feeling, rather than of acute pain in the head, chiefly in the forehead over the eyes, and in the eyes themselves. These organs, if pressed upon or turned upwards, are found to be very painful.

There is often giddiness, always great languor and depression, and a tendency to drowsiness and sleep, which, though deep, is not refreshing. The conjunctiva, or white portions of the eyes, are sometimes slightly jaundiced. There is very generally nausea and vomiting, and after continuing for a longer or shorter time the attack is, not uncommonly terminated by vomiting of green bile, often in considerable quantity. The bowels in such circumstances have most probably been irregular for some days previously, perhaps obstinately constipated. Many persons suffer from frequently recurring attacks of bilious headache, while others, by a careful attention to diet and regimen, contrive to ward them off. Those who are apt to be thus affected should exercise great caution in the matter of food. All rich articles should be avoided, such are by no means, well named bilious; nor should less care be exercised in regard to what is chosen for drink. Bilious subjects should learn to avoid highly dressed meat, and such like, pastry and malt liquors, plainly dressed and well cooked meat, and not much of it, farinaceous food, and for drink, a glass of cherry wine in water, or the lighter wines are more suitable, as to tea and coffee, they sometimes disagree with such persons, and if so, milk, cocoa, or chocolate may be substituted. The bowels must be carefully regulated. It is surprising how much may be done in this way without having recourse to medicine. By due attention to diet and regimen, the healthy action of the alimentary canal may often be maintained. For the relief of the headache, however, a dose of laxative medicine will generally be found indispensable, let it be if sulphate of magnesia, a Sedlitz powder. Eno's Fruit Salt, or Lamplough's Pyretic Saline may be used, let cold be applied to the forehead, and, while the headache lasts in a severe form, let the patient practice abstinence; when the headache has abated, if appetite speedily returns, as it sometimes does in a keen degree, let there be indulgence to a limited extent only in what is simple food of easy digestion. Delicate women and young girls affected by anaemia often suffer from attacks of bilious sick headache which may be periodic and connected with uterine disorder, or monthly irregularities. Such cases have been termed *megrims*, and are best treated by rest, quinine, and liberal diet with ferruginous mixture (Griffith's) and some bitter aperient, such as the Decobition Aloes are useful in the intervals. Another remedy for this form of headache has recently been found in Phenacetin, which is highly spoken of, one lozenge of Phenacetin containing 4 or 5 grains should be taken on the first appearance of the attack, and the patient directed to lie down in a darkened room, a second dose may be taken after an hour, and, if necessary, a third and fourth; but

the second is usually sufficient to bring on a pleasant languor, which is succeeded by relief or complete recovery.

Bilious fever.—This form of fever frequently passes under the name of Bilious Remittent fever because almost invariably associated with symptoms of disordered liver, such as the existence of pain or tenderness over the hepatic region and a sallow colour over the surface of the body. It occurs chiefly in warm climates produced by malarial causes, the presence of much moisture, and of decaying vegetable matter, there is usually chilliness or rigors, hot dry skin, intense headache, aching of the back and limbs, scanty and high coloured urine, disordered bowels, and sometimes vomiting of biliary matter. Fevers thus characterized are not unfrequently relieved by a dose of calomel and James' powder (4 to 5 grains of each) followed by a dose of Castor oil. Subsequently rectrices should be had to some febrifuge remedy, and none is better than the ordinary diaphoretic or fever mixture given in appropriate doses, every two or three hours until the skin becomes cool and a free perspiration established. The warm bath, or the application of hot fomentations over the right hypochondrium, should not be neglected. During the remission of fever, when once the state of the bowels has undergone improvement, quinine should be administered in proportionate doses (3 to 5 grains) in combination with dilute aqua Regia and Spirit Ether Nitrosi, twice or three times a day, until complete cessation of the fever. The following usually answers well:—

R Quinise Sulph.	gr. iii.
Dilut Aquæ Regiæ	℥ x.
Spt. Ether Nitrosi	ʒ ss.
Syrup. Aurantii	ʒ i.
Aquæ	...	ad	ʒi. misce.

fiat haustus, ter in dies sumendus.

There is a similar form of fever prevalent in childhood, to which the name of Infantile Remittent fever has been given. Children from two to ten years of age suffer from it most frequently, usually the affection comes on suddenly, and the febrile excitement runs high. But after the continuance of a hot skin, and quick pulse with pains in the limbs, back, and head, loss of appetite, and other feverish symptoms for some hours, these all, undergo a great change, becoming much less observable; and, when morning arrives, the child is found almost free from fever. As the day advances the condition of feverishness returns, and so the disease continues for five or six days' but it may be also for weeks. This form of fever observes no definite duration, the length of the illness will depend chiefly on the treatment. With these symptoms there is very generally found some sufficient cause of irritation, perhaps in the mouth, the child outting its teeth at the time, or as happens more frequently, in the stomach and bowels. The latter are generally coative or relaxed, or both alternately; the evacuations dark or clay coloured, worms, moreover, are often present. The child is irritable and very fretful. Cases of this nature must always be carefully watched for during their progress, various symptoms of a serious and alarming nature are apt to be developed, sometimes connected with the head, sometimes with the chest, or convulsions may supervene through the medium of the nervous system to the brain, dependent in

the process of teething, which is often difficult in some children.

In the early treatment of such cases, a hot bath, and a dose of calomel and James' powder so as to affect the liver and act upon the bowels, are generally serviceable. While the disease lasts, diaphoretics or febrifuge medicines, and small doses of rhubarb and magnesia (Red mixture) should be given to regulate the bowels, unless diarrhoea exists; and if so, lime water, with a little milk added, will be found useful. In this disease as in enteric fever, it is of great importance to watch the state of the alvine secretion, both before and after the administration of medicines. During the remission of the fever, quinine hydrobromas should be given in doses according to the age of the child (1 to 2 grains or more, three or four times, at intervals during its continuance). The diet must be carefully regulated, very gradually from a wholly milk and farinaceous diet may one of mixed animal and farinaceous food be reached; the latter including mutton and beef-tea, and chicken broth, etc. Before passing from this subject, a word may be added in regard to that ailment from which young children, particularly those who are subsisting entirely, or almost so, on a milk diet, are prone to suffer. An ailment characterized chiefly by an altered condition of the stools, their pale or even white appearance, owing to deficiency of bile, this state depends on an imperfect action of the liver. In such cases the tongue is generally white, a disposition to boils, sickness and thirst are other symptoms. This condition is best treated by the employment of alterative remedies; and of these, the gray powder (Hydrargyrium cum Creta). Pulv. Ipecac, and liquid extract of Taraxacum, are perhaps the best. The indication of amendment is the restoration of the natural appearance of the stools. The following powder may be recommended for children.

R Hydrarg. cum cretæ	gr. i.
Rhei Rad. pulv.	gr. iiss.
Ipecac. Rad. pulv.	gr. ʒ to gr. ʒ i.
Bismuth. Subnit.	gr. i.
Pulv. Aromatic.	gr ʒ
Sodæ Bicarb	gr. i. misce.

fiat pulvis, ter in dies sumendus.

A mixture of equal parts of black pepper, ginger and cinnamon, make a very good aromatic powder. Hepatalgia, or chronic pain of the side, is a chronic complaint, characterized by severe pain in the side and region of the liver. It is peculiar to females from the fifteenth up to the thirtieth year of age. It is extremely tedious and difficult to cure, recurring often with unconquerable obstinacy for a series of years, until some change in the constitution brings with it a natural cure.

From its leading symptom, it received the appropriate name of hepatalgia; but as the seat of pain is often on the left side of the body, that of laterodynia is perhaps more applicable. Of its intimate nature little or nothing is known with certainty. That it is not of an inflammatory character may be inferred from its duration, from the absence of constitutional disturbance, and from the small benefit treatment affords. Some pathologists consider the affection as of an irritative kind. We have often been inclined to view it as depending in some degree upon a distended state of the gall-bladder.

To this opinion we are led, first by the circumstance of its occurring frequently in young women of sedentary occupations or of inactive habits; secondly from its being sometimes accompanied with a waxy or sallow expression of countenance, analogous to that which occurs in jaundice; and thirdly, from the benefit afforded by such medicines as excite the torpid action of the liver and its ducts. We are well aware, that it is also a frequent complaint with young women who have over-exerted themselves, and the left side is perhaps as often the seat of pain as the right. It will therefore be more consistent with sound pathology to consider this affection as depending upon a distended state of the vessels of the liver, spleen and neighbouring parts. It is sometimes accompanied with symptoms, which indicate irritation of the urinary organs, produced by gravel or the passage of a calculus, along the ureter into the bladder. In many instances, it will be found to concur with a deranged, or perhaps completely obstructed state of the menstrual function. Costiveness is an almost invariable attendant upon the disease, and not unfrequently the most acting purgative medicines fail of their accustomed effect.

Treatment.—This complaint though very distressing is not dangerous. When the pain is very urgent, relief is attained by the application of hot fomentation to the side, of sinapisms, and of anodyne liniments. Occasionally it is necessary to place the patient in a warm bath, and a full dose of chloral hydrate or nepoche given every second or third hour, according to the urgency of the symptoms, but opiates should not be employed until the lower bowels have been freely emptied by a warm water enema, which of itself will generally afford considerable relief. Purgative medicines are indispensable in the treatment of this affection, the daily use of some aperient, such as Soda phosphus or the liquor Eucymin and Cascara Sagrada should be directed. In some cases, the complaint appears to be altogether a nervous affection, and is relieved by the application of a Belladonna plaster, and the internal use of some mild sedative, such as Bromide of Potassium or Succus conii. Galvanism may be tried with some advantage. Much benefit is derived from regular exercise, and change of climate has proved in many instances efficacious, not merely in the relief, but even in the permanent cure of the complaint.

Bilious diarrhoea, or Bilious attack.—This complaint is characterized by the sudden occurrence of severe vomiting and purging. The matters vomited and passed at stool contain usually, in the first instance, substances in a partially digested condition which have been taken as food. After a time, by vomiting and purging a large quantity of liquid is discharged, possessing the characteristic appearance of bile; the colour, indeed varies; it is at times quite green, at others yellow or almost brown, these, however, are the shades presented by vitiated bile, or bile which has been acted upon by the unhealthy ~~assimilation~~ during its passage through the alimentary canal. With the vomiting and purging are sometimes associated severe pains in the stomach and bowels; the patient often calls out from the violence of the suffering. Should the attack be a smart one, cramps in the muscles of the limbs and in those of the abdomen come on, and the patient's strength becomes much exhausted.

Coldness of the extremities, with a cool perspiration over the surface of the body supervene, and fainting is not unapt to occur. Happily, this form of diarrhoea is not a fatal disease in this country; nevertheless there are unquestionably not a few instances of death occurring from it, when it attacks the old and infirm. It is most to be apprehended. Attacks of bilious diarrhoea are infinitely more common during summer than at any other season. Heat exercises a remarkable influence over the functions of both liver and bowels. Every one knows how common in tropical countries are affections of these organs. We see evidence of the same in the frequency of attacks of biliary derangement, and especially bilious diarrhoea, during summer, and more particularly if the season be unusually warm. Besides the influence of an exalted temperature, or the accidental exposure to cold after the continuance of the former for a time, in determining attacks of bilious diarrhoea, it will very generally be found that some error in diet has been committed; the drinking of acid wines, elders, or other beverages, or partaking of sour or unripe fruit in many instances may be ranked as the exciting causes of the malady, and it often occurs in persons just landed from a sea voyage.

As to the treatment of bilious diarrhoea most physicians are agreed that the diluent plan pursued by SYDENHAM, is in the great majority of cases, the safest and most proper. The employment of purgatives, on the one hand, or of astringent remedies on the other, is generally regarded as inadmissible. In the very earliest stage of the disease, and more especially if it has distinctly followed some error in diet, the former plan may be adopted; but the probability is, that the remedy employed, whatever it is, will be speedily rejected. If during a summer season, specially an unusually hot one, a person be suddenly seized with bilious vomiting and purging, accompanied by severe pain in the stomach and bowels, cramps in the limbs, and succeeded by a sense of faintness and exhaustion, let diluent drinks be administered, soda water, barley water, or weak chicken broth (the latter was strongly recommended by SYDENHAM); this may be taken by the mouth, in small quantities at a time; and it is surprising how much relief their administration affords. "This method of diluting the humours," says SYDENHAM, "is much safer and shorter than the common practice of evacuants and astringents." Ice, in such circumstances, is often a grateful remedy, it tends to repress the most uncomfortable feeling of nausea, and has all the good effects of a diluent. If, notwithstanding this plan, the symptoms continue, and there be any marked evidence of prostration of strength, which is always to be apprehended, then an effervescing draught with ten or fifteen drops of Tinct. Opii every hour, for two or three doses, and some times a dose of chlorodyne, answers. When the powers of life are waxing faint, when the pulse begins to grow feeble, still more if it flickers, when the surface of the body becomes cool or cold, if bloocp, at such a time a most unfavourable symptom occurs, then stimulants are to be given; and of these the best is brandy, warm brandy and water. Soft the precise strength of the mixture to the patient's taste, but let it be fairly strong. When thus seriously affected, the patient must not only be confined

to bed, but permitted to move in as little as possible; the head kept low, so as to obviate the tendency to syncope. A good application at intervals of such cases is a liniment over the stomach and bowels, or hot bran in a flannel bag, or a hot fomentation of flannel with a little oil of turpentine sprinkled over it. Friction with the hand or any stimulating liniment, will tend to relieve the cramps of the limbs; and, if they are very severe, the application of a ligature or tight bandage round the limb and above the seat of cramp, may serve to arrest them altogether. From severe attacks of bilious diarrhoea recovery is often very slow; let this be kept in mind; and, above all, let no articles of food, but what is safe, easily digested, as well as nutritious, be administered, till convalescence is far established.

Disorders of the liver are far more common in tropical than temperate climates, and there is little doubt over-indulgence in alcoholic stimulants, and too rich a diet, together with high temperature and malaria, account for their greater frequency.

—10—

INCREASED MORTALITY FROM FEVERS IN THE CITY OF MADRAS.

By JAMES HARRIS, L.M.S.

Medical Practitioner, Madras.

Dr. W. G. KING, our Sanitary Commissioner attributing the increased mortality from fevers in Madras to the subsoil water, which was criticized in the *Record* some time ago, reminded me of an incident in my practice. I was called to attend on the daughter of an old Anglo-Indian of Madras, for enlarged spleen. As a resident for nearly sixty-five years, he said with authority, that before the introduction of pipe-water, cases of malarial fevers were unknown in this city. I was at once convinced of the truth of this statement by bringing to memory, the fact of hardly even seeing in the general hospital a genuine case of pronounced malaria with the classical symptoms, said to have been admitted from the city itself about ten or fifteen years ago. We students used to seek for the origin of the poison in the wilds of Cudappah or Kurnul or in some insignificant up-country villages.

The scene is changed. The then Black Town of Madras is blacker to-day and exposes a dark and horrible picture even to a casual observer.

Several pregnant women have been seen with spleens too large to admit completion of gestation, children, even infants are found with spleens and livers occupying their whole abdominal capacity. Pale yellow youths with attenuated extremities often present a pitiable sight. Advertisements in every medicines vendor's shop are glaring with invitations to obtain ague mixtures and pills.

Could this transformation be due to the magic effect of of feeding our innocent city with the philanthropic pipe-water introduced from a distant red hill?

Slow to work, too ready to enjoy, how the Madrassie is able to keep his bangles of gold and dazzling ear-ring has been always a puzzle to me. He bathes regularly, he washes his clothes, he waters his garden, delegates his forefather's house regularly every day with an abundant supply of water. In short like a mermaid he is always in the water.

Want of thrift and wanton extravagance are his inherent qualities.

It is astonishing how his lavary inclinations vanished when he depended for his resources on wells and indirectly on the activity and whims of his females. The city is deluged all at once with water, though in pipes. He waxes tape at the main door, in his yard, in his kitchen, in his latrine, in his first floor, in his second and with the help of a pump, an equal number in his third. The absurd extent to which a Madrassie could waste the municipal water is seldom realised unless seen by one for himself.

The city is situated in many places below the sea-level and the various undulations instead of collaterally bleeding into a valley and inclining towards the sea, form isolated lakes defined vividly on a rainy day. In several places in the city there is subsoil water as indicated by the local wells within a very few feet of the surface. And this water as indicated above is almost stagnant, its increase and decrease are mainly influenced by rain, droughts, evaporation.

I will divide Madras into two periods:—Antideluvian or well water period, and deluvian or pipe-water period. We see a few engines pumping away the overflowing of sewers in a few corners of this very vast city; and the sanitary heroes, and the city fathers profess themselves satisfied with the result. These energetic engines which work day and night, instead of decreasing the subsoil water, only prevent the ill-laid roads being flooded by the stinking sewerage. Insufficient drainage together with the disproportionate inflow of pipe-water, added to the periodical down-pour of rain keeps the subsoil water at its highest level.

Whereas, in the antideluvian or well-water period. (1) The absence of the pipe-water and (2) the constant use of well-water for all purposes tended to keep the soil dry by lowering the water level.

Thus we see that there is a decided increase in the subsoil water in a city topographically unfavourable to the introduction of effective drainage. Has this increase in subsoil water anything to do with the increase of fever. I must emphatically say with Dr. KING, yes.

To confirm my statement I will not go beyond clinical facts. The most important of these being the striking distribution of cases of malarial fevers along the lowest levels of the city. Starting from the sea, if one were to walk across Black Town towards the west, he cannot but be struck with its marvellous undulations and the most ordinary observer will be naturally inquisitive to know what effective drainage the city has adopted.

The area indicated is a bed of malarial germ. To live in its vicinity is to find an early grave from enlarged spleen. In some homes as many as ten and eleven have died from the same cause. Similar localities are numerous. In all such places you will find a sluggish drain left to the mercy of the fishers' diurnal visits and the engine's pumping capacity.

As another important cause for the increase of mortality from fever may be mentioned the fact of the alarming increase of population. In houses fitted for a

Another misfortune to Black Town is the rapid erection of high edifices on its windward side. In some instances they completely obstruct the breeze and in the immediate vicinity of these buildings in the south-eastern corner of Black Town, there are a few streets which are dreaded as traps for human life. I know of 5 deaths from spleen in one of these streets within a year.

The erection of a public latrine by the Municipality in the Esplanade, is a sanitary error. The stench that emanates from it is a smart whip to the pedestrian and the equestrian alike.

The majority of the houses in Madras are now very old, sixty or seventy years; the walls, the floor and almost every portion of these houses absorb moisture and are unfit for habitation. The Municipality should insist upon such houses being sanitarily restored. In some houses cholera repeats itself in every epidemic with astonishing accuracy; and from many diseases is never absent.

The admixture of sewage with pipe water is a serious contamination and therefore an important factor, in increasing disease under the head of fever. I was surprised to see a pipe that was running across a drain leaking when the drain was particularly dry and I made this an occasion for some interesting observations. The pipe led to a large factory equipped with pumping machines and every time the taps and pumps were closed, there was an outbreak of leakage, on the other hand the opening of the taps and the pumps not only completely arrested the leakage, but enabled the pipe to take in a large quantity of water.

What about the sewerage system, the stumbling block of every city engineer? How a magnificent system of sewerage of a vast city, under the assumed name of sewerage, can be constructed and that done by Government men at the expense of the nation, is a mystery.

The open drainage system has converted the city of

Madras into a sewer. I have seen the streets of Madras by day (1). The rain, and the sun, make a peculiar phenomenon of the streets and houses and gardens of Madras in their impure condition.

Another important factor in the spread of fever is the indiscriminate statistics of the health department by the help of the ignorant practitioners and uneducated citizens, by recording several cases under the head of fever.

It will append this article, beyond making it a attempt to travel over more ground, confined to my own observations, Quacks, Placemakers, Antiquaries, and various regulations to protect private life, all unscientific help in swelling the list of those that count.

In conclusion I must say that there is an unfortunate tendency in every one to hold the Municipality as entirely responsible for everything that goes wrong in the city. Suppose the Municipality represent the head of the great Sanitation, and the citizens his members, and if the head is quite alive to all the dangers of contamination which the members lie paralysed, indifferent, and slothful, what benefit is there? From the ranks of the most educated Hindus garbed in gowns and bands, I can produce men who believe that small-pox and cholera are the angry manifestations of a displeased godhead. There is almost in every street a devil-dance in the time of an epidemic and not the slightest notice is taken of the cleanliness of their homes or their streets. Unless the citizens are alive to the importance of sanitation what can the Health Department which I see is actively engaged in purifying the city, with their new active Health Officer, do? He ever helps those who help themselves.

NOTE.—In Dr. Harris' welcome contribution to the subject of the great mortality from "fever" in Madras, the writer, who has taken both the point of Dr. King's Sanitary Report, and of our criticisms of it. Dr. King maintained that *faustations* in the subsoil water level were responsible for the excessive mortality, and gave a table which he said, "proves that this connection between subsoil water *faustations* and prevalence of fever exists."

We on the other hand proved from his own table that, using the word in its usual sense, *faustations* had nothing whatever to do with it.

Our correspondent appears to think that a high subsoil water level in Madras is a cause of the excessive mortality, it may surprise him to hear that Dr. King held the opposite opinion. He says, "It seems unlikely to be the number when a high subsoil water level prevails than when any marked depression occurs."

We hope Dr. Harris will do us the favor of reading Dr. King's Report and our criticisms (to be found in the issues of February 1st and 15th, 1895) over again.—(H.N., 1, M.R.)

REMARKS ON THE SURGICAL TREATMENT OF CATARACT BASED ON SEVEN HUNDRED AND THIRTY CASES OF EXTRACTION.

By BARNET F. NEVE, M.D., F.R.C.S., Ed.

Surgeon to the Kashmir Mission Hospital.

General results.—Successful 577; failed 36, left hospital, result unknown 14. In the last 200 cases the percentage of failure has been reduced from 6 per cent. to 3 per cent.

An analysis of these results and of the progress which have produced this marked improvement, shows that:—

(1) Careful selection of cases is the most important factor of success.

(2) Hardly second to the selection of the principles of cataract surgery, is the selection of cases involving somewhat wide application of these very principles.

Published by the Kashmir Mission Hospital, at Srinagar, Kashmir.

plex. It is impossible to render the conjunctiva and sclera aseptic in an absolute sense. But we can remove many of the conditions and much of the material which would allow septic organisms grow and multiply and prevent infection to our fingers and instruments. Absolutely aseptic introducing concentrated sepsis.

The importance of healthy conjunctiva and lachrymal sacs can hardly be over-estimated. Unfortunately many patients who present themselves for operation have very unhealthy conjunctival sacs. Thus cataract patients have come to us suffering from ectropion, entropion, blepharitis, trachoma, pious and a variety of forms of conjunctivitis. If the surgeon consider only his own reputation, he will eliminate all cases of this kind. But I think his aim in selection should be, not so much to reject, as to subject cases of this sort to such preliminary treatment as shall give the patient a fair chance. This may entail some sacrifice. No doubt the number of failures will increase. But on the other hand, many patients will obtain vision who otherwise would have been condemned to hopeless blindness.

Of 32 cases of trachoma, in 20 the result was good, 6 fair, 5 poor, and 1 not improved. There were 123 cases in which the eye was irritable, watery, red and gummy in the morning or showing other signs of conjunctivitis. Of these the results were 86 good, 21 fair, 15 poor, 10 not improved. Most of these underwent preliminary antiseptic treatment with solution of Nitrate of silver, followed by daily repeated instillations of zinc sulphate or boracic lotion. But the percentage of failure is high. Increasing care and experience tends to lower it somewhat. Thus in our last 300 operations, out of 62 cases with conjunctivitis there were 4 failures only.

Next to the influence of selection and preliminary antiseptic treatment, no doubt rigid sterilization of instruments, dressings etc., is most important, just as important as in general surgery. For the first 530 cases our routine was to place all instruments in 1-20 carbolic lotion and transfer them immediately before the operation to a saturated solution of boracic acid. For our last 200 cases we have as a rule boiled all instruments, except the knife and forceps-shell spoon which are placed as before in carbolic lotion.

Atropine and eserine lotions are prepared with 1% perchloride of mercury lotion. The cocaine solution is freshly prepared for each case. Salalambroth wool and for deep dressings the double cyanide gauze are used.

The surgeon's fingers should also be rendered aseptic. The room should be free of dust, above all of the dust of septic discharges. For this reason cataract extraction should not be done in a room where out-patients are seen. With these precautions the danger of septic inoculation from without is practically excluded.

Next in importance as affecting results, I should place the condition of the eye with regard to the presence or absence of the remains of previous disease. Former iritis exercises a peculiarly prejudicial effect. In our last 500 cases I find that we had 12 in which there were signs

of previous iritis, varying from some of the most severe adhesions to the lens to those in which there are a few posterior synechiae. Any improvement obtained in the worse type of cases of this kind may be regarded as quite a surgical triumph. I remember one case, in which even after a successful iridectomy obtained by a preliminary iridectomy, it seemed doubtful whether I should be able to extract the lens, and yet this presented no insuperable difficulties and an excellent result was obtained. In the remaining 11 cases the result was, fair 5, poor 5, not improved 1.

How far is it worth while to extract cataracts associated with glaucoma? If mature, the removal of the lens is advantageous. Probably a previous sclerotomy is wise in order to diminish the tension and risk of vitreous loss and hemorrhage.

In three cases of cataract and glaucoma, the result was poor in every instance. In seven cases of deep seated disease, retinal atrophy, choroiditis, etc., the results were, 3 not improved, 4 poor.

With regard to the actual operation of extraction, the points which come up for consideration are (1) the incision, (2) iridectomy, (3) capsulotomy, (4) accidents.

(1). *Incision*.—In our last 500 cases, Von Graefe—367, modified flap, 108, small 171, below, 6, irregular 2.

If too peripheral, the danger of vitreous show is greatly increased. There is a zone just within the corneo-sclerotic margin where the iris is especially apt to prolapse. In the modified flap operation which is further from the periphery, this accident is quite rare.

(2). *Iridectomy*.—In 500 cases, this was performed 371 times. In 32 of these it was done some days before the operation as the eyes were doubtfully healthy. I regard this preliminary iridectomy as a valuable precaution. But it is not quite free of risk. In one unhealthy eye, it was followed by panophthalmitis. In 129 cases, no iridectomy was done. It is interesting to note that of these in 10 there was subsequent prolapse, 7 incarceration, 10 adhesions to cicatrix, and 11 sharp iritis followed in 6 cases by total, and in two cases by partial occlusion. While the excellence of the result in successful cases is most gratifying, this increased liability to prolapse is just the weak point of the operation without iridectomy. No doubt the patient is sometimes to blame, but when the iridectomy is omitted, it seems to me, the surgeon can never be certain that he will not find a prolapse at the first dressing. The danger of occlusion appears to be also increased.

(3). *Capsulotomy*.—The attempt to extract the lens in its capsule is nothing new. The names of RUMSTEDT and MACNAMARA have long been associated with this. Recently MALBONY of Amritsar and others have strongly advocated and practiced extraction without iridectomy or the use of the scoop, by a rather large semilunar incision below.

The amount of force required and the large size of the incision appear the chief objections. The frequency of vitreous loss is bound to rise. We have performed the operation 19 times. In no less than 7 there was a vitreous show. This seems to me prohibitive. I have also seen (elsewhere) a case of cystitis following this operation. This may however have been a case of gonorrhea and not pyelitis.

The following statements were prepared by:

For vision of . . . finger counting with this side of thumb
at least than 100
For vision . . . finger counting at least than 100

(4) Inflammation of the eye, arising from the use of the knife, is not infrequently a serious complication. It is best to avoid this by using aseptic technique. The use of the knife by the patient himself is dangerous and should be avoided. It is better to use the knife in the hand of the operator. In our last 500 cases, in 5 there was vitreous show, in 10 there was vitreous loss, in 15 there was vitreous loss and prolapse of the iris. In one, the patient moved the head with a jerk as the iridectomy was being performed and the whole circumference of iris came away. The operation was not proceeded with. In two others the iris was very friable, and was partly detached by the point of the knife. In 46 cases altogether, there was vitreous show or loss. In 6 of these, there was a rush the moment the incision was completed; of 9 cases in which the knife was used, in 5 there was vitreous show, of 14 cases in which the lens was hooked out, in 7 there was vitreous show. As already mentioned in 7 out of 19 cases, in which it was attempted to extract the lens in its capsule, there was vitreous show or loss. On the other hand, the omission of iridectomy, decidedly diminishes the risk of vitreous loss, but then unfortunately it increases the danger of prolapse of the iris.

In one case of fluid vitreous loss with hemorrhage into the anterior chamber, the lens became dislocated backwards and the operation was not completed.

It is difficult to obtain a complete list of inflammatory sequelae. I fear many cases of slight iritis, adhesions to the ciliary, etc. have escaped record in our notes.

In our last 500, as nearly as I can make out, they were as follows: Panophthalmitis 5. Septic infiltration or elongation of cornea together with iritis, 3. Iritis 60, resulting in 13 cases in complete, and in 6 cases in partial occlusion. Irido-cyclitis one, subsequent glaucoma about 5.

Summary.—(1) Careful selection of cases is the most important factor of success.

(2) Hardly second to it is the employment of scrupulous antiseptic technique.

(3) A large percentage of eyes, the conjunctival sacs of which are in a doubtful condition, can nevertheless be operated upon with success after careful preliminary antiseptic and astringent treatment for days or weeks.

(4) Under such conditions however, naturally, the percentage of failure rises sharply.

(5) But the measure of success attained, amply justifies the additional risk.

(6) Previous iritis has a particularly prejudicial effect on the result.

(7) The omission of iridectomy, while producing excellent results in the majority of cases, does undoubtedly increase the risk of prolapse of the iris and also of occlusion. On the other hand, the danger of vitreous loss is diminished.

(8) The attempt to extract the lens in its capsule is a dangerous attempt with vitreous loss, and it should be resorted to more when the lens is small.

(9) An incision around the cornea, and the use of the long-handled forceps, is the best method of extracting the lens.

A WOMAN AT FORTY.

REPRODUCTION AND RECOVERY AFTER TEN YEARS;
TUBERCULOUS MAMMARY ENLARGEMENT AND
OBESITY; CURRENT TREATMENT;
UTERINE STIM 15 YEARS
LATER.

BY JAMES R. WALLACE, M.D., F.R.C.S.

*Fellow of the Obstetrical Society of London,
Formerly Resident Surgeon to the Johns Hopkins Hospital for
Women and Children, Baltimore.*

Mrs. —, an Anglo-Indian lady, 25 years of age, one of a family of six children, two of whom are dead, and three are slightly built. She is one of the stout ones. Her parents are both stout. She began to menstruate at 12, and was of spare body at that time. She was quite regular in her courses, both as to time and quantity. She married at 23. Her husband married with her 8 months and then left her on the plea that they were not rightly mated sexually. She was sexually impotent. She did not conceive. She menstruated regularly during the first eight months of her marriage, that is, while her husband lived with her; but with his departure in 1892, she ceased to menstruate. At each subsequent month for 4 days, corresponding with her catamenial epoch, both her mammary glands became swollen, hard, painful and full of milk, which poured away freely from both breasts. It diminished after two days, and quite stopped on the fourth day. She suffered from no pain about the pelvic organs during this period of vicarious "menstruation," and beyond the tenderness produced by this periodical mammary turgescence, her health suffered in no way whatever. This regular change began with the "period" due after her husband's disappearance, and continued up to the time she consulted me in February 1898, i.e., for six years nearly! Another marked physical change which was concomitant with the stoppage of the regularly menstrual flow, was the rapid development of obesity. She weighed 7 stone at her wedding in 1892, and had reached the silly figure of 17½ stone in February 1898, when I weighed her. Her appearance at this time was one of perfect health. She presented the picture of a bright, energetic, well-fed, contented woman of 30, and was perfectly robust and healthy complexioned. I was called to see her in February, 1898 for a sudden attack of catarrhal fever. Her temperature had gone up to 103, and she was delirious and suffering with a deal of pain and tenderness about her hypogastrium. I heard the history of her life, but did not feel convinced at the time that the female disturbance was in any way connected with her strange menstrual experiences. With diaphoretics and sedatives the acute trouble passed off, but the uterine distress continued, and with it, the usual mammary engorgement and lactent secretion. With such a respectable and antecedent history of functional generative disturbance, I surmised that the present unusual symptoms were connected with undue exaggeration of uterine effort to obtain menstruation by the natural channel. I therefore suggested the use of an inert dilator stone, which was introduced on the 25th February. This operation was followed in twenty-four hours by a discharge of blood per vaginam, which

lashed for four days. Four weeks later, when another attack of fever with high temperature, tremor, and temporary turgescence, which however was less than usual, and subsided within a few days. Every month since then, the symptoms have come with perfect regularity with an interval of four weeks, lasting freely for four days, without febrile disturbance. The menstrual engorgement has steadily decreased each month, till now there is scarcely more than a sense of mere fullness, without tension of pain, and absolutely without the formation of any secretion. Another very remarkable and very welcome change to the patient, is the lessening of her bodily weight, for she has lost more than two stone within the past six months. No medicines have been given, and every beneficial change that has resulted, must be attributed to the use of the intra-uterine stem, which was kept *in situ* for six weeks only.

Remarks. This case is remarkable in emphasising the strange incidence of a pathological arrest of a physiological function, dependent entirely upon the withdrawal of sexual stimulus. Such a pathological phenomenon is all the more remarkable as occurring in a woman, in whom the sexual appetite,—as gauged by the entire absence of sexual orgasm,—was so completely in abeyance.

—:—:—

A CASE OF CEREBRO-SPINAL FEVER.

By COLONEL R. C. SANDERS, M.D., F.R.C.S., I.M.S.
Surgeon Superintendent, Mayo Native Hospital, Calcutta.

The patient named GANODA, aged 12 years, a Hindu, resident of Sobhabazar, Calcutta, was admitted into the Hospital on the evening of the 10th September 1898.

Condition on Admission:—The patient was a fairly nourished girl; completely unconscious, pupils dilated; conjunctival reflex absent, respiration hurried, pulse soft, small and frequent, 110 per minute, and respiration 30 per minute, skin hot and dry; Temperature 102.4. There was lateral deviation of the head and the eyes to the right; spasmodic contraction of the muscles of the hands and feet was marked, abdomen was retracted. There were no convulsions, nor tetanic spasms.

Liver and spleen were not enlarged. Tongue dry and furred.

Heart sounds weak and normal. Respiratory murmur normal.

There was a swelling of moderate size of the right Inguinal region but the part was not tender.

There were no eruptions anywhere in the body.

History of the Case—Could not be accurately obtained, the girl has stated to have been suffering from fever of a remittent type for the last three weeks, and became unconscious, accompanied with the symptoms above described for the last five days. Previous to the present illness she was in good health.

Subsequent Progress:—The temperature next morning rose to 103.2, pulse small, thin, and frequent; and 125 per minute; Respiration hurried and irregular; Bowels not moved; Ticks convulsed without marked twitching of the small muscles of the hands and feet occurred; lateral deviation of the head and the eyes continued; the swelling of the inguinal region remained the same.

The patient gradually became worse; Respiration laboured and irregular; the tongue more furred;

more generally perceptible at the wrist; and died in the evening at 4 P.M. on the 15th September 1898. The final termination of the case was preceded by a rise of temperature to 107°.

Treatment.—The patient was on Emphyseum with Pot. Bromide &c., as well as on stimulants of all sorts. Ice was applied to the head.

Diet was milk and sage, chicken broth. The administration of medicines and diet was conducted with difficulty as the patient refused nourishment.

Extract from the post-mortem report of the case:—

"The post-mortem examination was performed 16 hours after death.

"Rigor mortis, was well marked:—In the abdomen, no excess of fluid in the peritoneal cavity was noticed, liver and spleen were congested, kidneys presented no abnormality. Patches of congestion and ulcerations were noticed in ileum as well as in the large intestine; small tubercular ulcers were found on the lower end of the large intestines; mesenteric glands were enlarged.

In the chest—There were adhesions between the visceral and parietal layers of the pleura of the left lung. The right lung was free from adhesions. Few scattered tubercles were found in the lungs.

In the Heart.—No abnormality was detected.

In the Brain.—The membranes were much injected. There were adhesions of the membranes in some situations especially at the surface and posterior aspects. There was an abundance of lymph on the convexity of the brain. The ventricles of the brain contained an excess of serous fluid. There were about 6 drams of fluid in the base of the skull. The membranes of the spinal cord were also considerably injected, especially at the posterior surface, and in the lumbar region.

Remarks.—The case was brought in in a low condition, and was under observation in the hospital for about 26 hours. The history of the case was not accurately obtained. The condition of the patient; the symptoms above described; the post-mortem examination exhibits the case clearly.

Cases of this nature are easily mistaken for those of plague, from which they should be carefully distinguished.

—:—:—

ABORTION DUE TO QUININE.

By ASSISTANT SURGEON BALAGAPAI, M.B.
Chhatrapur, Sundalband.

Mrs. B. aged about 21 years suffered with Malarious Remittent Fever for 10 days. On the 11th day, the temperature came down to normal. I prescribed 2 grains quinine in a mixture to be taken three times a day. After the 4th dose of the mixture the lady, who was in the third month of pregnancy, began to feel pains in the hypogastric region. The pains commenced in the morning, but her friends informed me of them in the afternoon. I at once administered 30 drops of Tincture of Opium with an ounce of water and gave Liq. Opi. 10 drops with a little water half an hour after the first dose. Five minutes after the administration of the second dose, she had four pains successively with very little interval between each. After the fourth pain she called for the same and said that she had laboured.

The case shows that the dose of quinine in any form is not abortive, is quite innocuous and should be administered to pregnant women.

Public Health Journal

IMPROVED CITIES OF THE FUTURE. BOMBAY AND MADRAS.

I. BOMBAY.

WITHIN the past month two announcements have appeared in the daily press, which although by no means startling or sensational in themselves, are closely connected with two of the most important sanitary problems which at present face us in India; the questions of the future of Bombay and Madras.

In the first place we read that the Bombay City Improvement Act comes into force from the 9th of November.

And in the second, that the Government of Madras have called upon the Sanitary Commissioner for a report on the late and present evil conditions prevailing in that town, with a view to finding out the cause of the late rapid rise in the death-rate.

It would appear as if disease and death had marked out these two great centres of population as their own: that it should be so, is a deplorable commentary upon the methods of sanitation pursued in India. It takes the wind out of the sails of our boasted progress, and seems to point the finger in scorn and derision at the word *knowledge*, we are accustomed to write so large, as if ignorance would be more appropriate to our present blind gropings after sanitary perfection.

Bombay has been in the death grip of plague since August or September, 1896, and has now entered upon its third epidemic. As far as Bombay is concerned this fact overshadows everything else, and draws the attention away from other evils less in themselves but still of great importance.

At the present day when we find ourselves face to face with great outbreaks of epidemic disease, it is the custom for medical experts to point out some special bacillus and declare that it is the cause of all the mischief: in this way their ignorance is cloaked and their conscience soothed.

We are told that the discovery of these bacilli marks one of the most important advances ever made in the study of the origin of disease, this may be so, but so far its practical application to the prevention and cure of disease has not made much progress.

The fact appears to be too often lost sight of, that the identification of the bacillus far from being the end of the matter, is in reality only the beginning; beyond the bacillus many questions of the greatest importance arise, which are answered by the valiant and most trifling of means.

What are the conditions which favour the growth of the bacillus? What are its requirements? What are the conditions which favour its dissemination? What are the conditions which favour its destruction? These are the questions which should be asked, and which should be answered, before we can hope to control the plague.

The conditions which favour the growth of the bacillus, and the conditions which favour its dissemination, are the conditions which we are most ignorant of, and which are the most important to be considered. It is not enough to know that the bacillus exists, we must know the conditions which favour its growth and dissemination, and which we can control.

Our knowledge of most health as regards its relation to the characters they present in the body, or under the artificial conditions of the laboratory, and the conditions outside the body we are mostly ignorant, though it is assumed and not without good grounds that this, and other and other insanitary conditions provide these with a favourable environment.

It appears to have required the terrible ravages of plague to open the eyes of the public and of the authorities to the terrible neglect of hygienic rules which prevailed in the City of Bombay.

The following is a graphic representation of one aspect of this neglect.

"The *chawls* or tenements may run up to seven stories and the unit of construction is a long corridor with rooms opening on either side. In the corridor, either at one end or in the centre, is situated a *chhatra* with bathing platform, and alongside it a latrine with two or three seats. The whole tenement is built up of a congeries of these corridors and rooms, and contains from 500 to 1,000 individuals. The only space between each tenement is a gully sufficiently wide to admit a sweeper. In most of the corridors and rooms, either from the absence of openings or from the obstruction of the existing ones, there is absolutely no light admitted and consequently no ventilation.

"The Health Officer informed me, that he estimated that 70 per cent. of the population live in such houses. The corridors, before being taken in hand by the Health Department, were the repositories of filth of all kinds, and it is surprising that the mortality under such conditions has been so small."

Overcrowding, filth, want of pure air and absence of sunshine form an infamous quartette whose potentialities for evil no man can gainsay; but in the present state of our ignorance it would be rash for any one to assert that the plague is dependent upon them and nothing else, or that they alone sin against the decalogue of sanitation.

In Bombay however, it appears that they have been accepted as the responsible agents, they have been publicly incriminated, and the New Improvement Act is mainly directed towards their elimination; the greatest energy is to be shown in grappling with them, congested areas are to be opened up, wide and airy thoroughfares are to take the place of narrow tortuous lanes, and a new style of dwelling, regular temples of hygiene, are to replace the squalor of the overcrowded tenements.

But underlying all these things, and underlying the city of Bombay itself, lies a contaminated subsoil saturated by a stagnant subsoil water.

It should turn out, and there are many reasons to believe it will, that this condition of the subsoil is responsible for much of the suffering which Bombay has undergone, more than the New Improvement Act is intended to relieve, and the department of public health, if it does its duty, will find its true work in the subsoil.

In last year the total rainfall was 55.5 inches; this, according to the authority 1819 and according to another 15 inches above the average. By the way it is interesting to note that the Sanitary Commissioner with the Government of India in his 1896 Report says, the rainfall was below the average, but this is of no importance.

In addition to being abnormal in quantity it was abnormal in distribution; it fell in six weeks instead of four months. In June, 29 inches fell, in July 25.4 inches, and in August 20.8 inches; this heavy rainfall flooded with sewage the low-lying portions of the city, through which the polluted streams, rushed in swirling currents, leaving banks of mud and sludge behind to ferment or slowly dry and, moreover, the sewage flowed from the sewers on to the streets after each heavy downpour and rushed up the traps and flowed on to the low-lying ground. After this heavy soaking the ground took a long time to rid itself of its superfluous moisture and although the monsoon practically ceased in the middle of August, the shady sides of the streets in crowded portions of the city remained damp until the end of August."

All this points to an unsatisfactory state of sub-soil drainage and also to what has often been noticed in connection with the outbreak of other epidemics,—the occurrence of unusual meteorological phenomena.

There are not wanting indications to show that altogether apart from plague, the health of Bombay is not satisfactory. Thus on 13th August, we read in the *Times of India*, that the mortality has been increasing for the last six weeks, that the increase from plague was only 37, while the increase from other diseases was 178. That the total mortality was 656, being 15 excess of the average for the previous five years.

Again on the 27th August, we read the same tale. The general mortality apart from plague is on the increase and what accentuates the fact is that this is a new experience, in view of the tendency of plague to overshadow all other diseases and cause a decrease in their mortality.

It is well-known that there is an invariable increase in the mortality in Bombay during the monsoon months, and it is admitted that this is occasioned by the prevailing dampness, which all points to the urgent necessity of drying the subsoil.

Of all the districts in Bombay the most unhealthy, the most overcrowded and about the lowest-lying is Mandvi, and it is in this district that plague finds its fittest residence, from Mandvi it has never been absent since it first broke out, and from this quarter each of the three epidemics has started.

Is the cause altogether in the above ground conditions as our sapient councillors would have us believe, or is not the saturated and contaminated soil also responsible for its due share of the havoc that has been wrought?

Of late years the subsoil water of Bombay has been steadily rising at the rate of about three quarters of an inch a year. Eleven years ago it was twelve feet below the surface, this time last year it was only four: two causes have contributed to this result, first, drainage originally insufficient, second the introduction of a plentiful water supply without any means of removing it. In this way a pure water supply instead of proving an unqualified blessing has proved to a large extent equally the reverse.

The first step to the regeneration of Bombay would be a complete and efficient sewerage system. If such a scheme is in existence, it only waits to be put into execution; with the soil in its present condition it will be little short of a sin to expend large sums of money in improving the streets and houses.

THE TOXIC THEORY OF THE ORIGIN OF DISEASE.

THE address in Medicine delivered at the Annual Meeting of the British Medical Association at Edinburgh, by Professor THOMAS RICHARD FRASER may be justly said to rank with the most important communications that have been made on the subject of the pathogenesis of disease; it should be read and re-read by every one who is anxious to keep abreast of the times, and to understand the complicated problems which at the present day stand in the van of medical progress.

Professor FRASER does not limit himself to a mere summary of the work that has been done, his horizon is much wider, and extends to a vast generalisation of disease with toxins or poisons as the universal cause.

Full of originality and suggestiveness he is not satisfied with presenting to us the intricate questions which are now vexing so many minds, he advances plausible and rational explanations of his own, and gives weighty reasons for differing from those of others; his criticisms, as might have been expected, are lucid and far reaching, and full of hope he gazes into the future with the prophetic eye of a seer and draws aside the veil of obscurity.

While micro-organisms occupy a considerable position in his scheme, he seems to avoid the tendency which disfigures so many present day writers of looking upon them as the be all, and end all, of everything, the absolute *ensæ quæ non*; he is able to look beyond them and treat them according to their merits.

He shows us that there are venoms and poisons as powerful and deadly as any that they can instil, and that many of these originate within the body itself, without their agency, and are a potent cause of disease.

Professor FRASER has long been known as a devoted student of these obscure poisons, and his authority to speak on these subjects is unassailable.

In the following passage the theory of the toxic origin of disease is lightly outlined.

"It is thereby shown that the disease is not truly a product of the structural alterations which are present, but of a hurtful substance or poison capable among other effects of producing these structural alterations. Similar facts are observed with many ordinary poisons, and an association, highly significant is traced to the production of disease, is thus indicated. Many of the more common poisons produce changes in structure typically simulating the changes of disease, as the peripheral neuritis, anterior cornual degeneration, granular fatty degeneration and arterial sclerosis of foot, the liver steatosis and yellow atrophy of phosphorus; and the fatty degeneration and diffuse sclerotic hyperplasia of the liver, the peripheral neuritis and the arteriosclerosis changes in blood-vessels produced by alcohol. The same facts, acquisitions of modern pathology, will strongly suggest that the structural changes found in many diseases may, after all, be more modifications, associated with

the body, which would then become the source of the disease, and the disease is thereby maintained.

It is not, however, the only way in which the state of health is affected. Numerous other substances, that produce various diseases, are of the chemical nature of the previously known poisons, which they rival in toxicity, and that by the same influence of substances formed in the processes of disassimilation, the symptoms of cholera, gout, rheumatism, uræmia, hæmorrhage, neurasthenia, asthma, and the idiopathic diseases receive a sufficient explanation.

And again we are told that auto-intoxication from poisons produced in the intestinal canal is believed to be a potent factor in the causation of insanity.

With regard to the infectious diseases we are told that the pathogenic micro-organisms connected with them cause their effects mainly by the poisons which they produce; many of these poisons are of extreme and almost indefinite activity, and as in diphtheria and other diseases they are capable of causing structural changes.

Having shown that large numbers of disease-producing poisons are ever present in the body, that many substances such as alcohol, tobacco and tea possessing poisonous properties are constantly introduced, and that micro-organisms capable of multiplying and producing large quantities of poison, are always present in the air passages and intestines, he passes on to consider the means of defence which the body possesses against all these enemies.

"A fundamental difference exists," he tells us, "between both congenital and acquired defence against ordinary poisons and that resulting from the action of disease toxins, venoms and such like poisons, in so far that in the former there is not produced in the blood any substance which plays the part of a counter-poison or antitoxin."

Artificial Resistance to Disease.—Into this very important and interesting part of the subject, Professor FRASER enters thoroughly.

In the first place he shows that the results which follow the experimental introduction of the pathogenic microbes of the infective diseases into the system, whether the appearance of the disease itself or the subsequent immunity, are due, not to the microbes themselves, but to the toxic substances produced by them; also that the blood serum of animals thus protected or rendered immune, though itself destitute of poisonous properties, when introduced into non-protected animals confers upon them a greater or less degree of immunity.

"These remarkable results," he says, "irrefutably demonstrate that infectious diseases are in their essence poisonings."

Much has still to be learned regarding, (1) the nature of the process whereby protection or immunisation is obtained; regarding (2) the origin of the protective products, antibodies or antitoxins; and regarding (3) the manner in which they act as counter-poisons to the pathogenic agents.

To explain the last three theories have been put forward, but none has been shown to be the origin of the protective products. It is the object of this paper to show that the protective substances which the body produces are of the same nature as the poisons which they are intended to counteract.

antitoxin, (3) the protective power of the serum, and (4) the nature of the protective products.

The theory, he suggests, is that there is a continual formation of intoxicating material in the body as long as immunity exists. The intoxicating material he thinks may be produced by an attenuated form of the original bacillus of the disease "so altered that its power for manufacturing poisons is weakened or destroyed while its disease preventing properties are retained."

In support of this he states that experiments have shown that both immunity and poisoning are equally dependent upon a soluble substance produced by the micro-organisms; it is necessary to distinguish clearly between these organisms and the substances they produce, for while these substances alone are capable both of causing the disease and of inducing a large degree of immunity, there is this remarkable distinction that the immunity brought about by these substances, is invariably of very short duration, 5 to 7 days with diphtheria toxin and only a few hours with serpent venom; while the immunity resulting from the introduction of the micro-organism may last a life time as for instance in small-pox.

"It appears to me impossible to explain these contrasting facts on any other supposition than that in the instances of prolonged immunity, successive supplies of the antitoxin of the disease must be furnished to the body during the time that protection continues."

Professor FRASER considers such phrases as "individual and racial peculiarities," which are so largely made use of to explain anomalous outbreaks of infectious diseases, the varying severity of different epidemics, and the many grades of intensity witnessed in different people etc., as unsatisfactory; all these peculiarities he would ascribe to variations in the microbe itself. The *diversus machina* which he is ready to invoke to overcome all difficulties is, variations in the virulence of the microbe due to the varying conditions of its environment.

THE ORIGIN OF THE PROTECTIVE PHASING SUBSTANCE.

Professor FRASER rejects the explanations advanced as a "reaction occurring in the tissues of the body, whereby either a proliferation of leucocytes and the production by them of the protective substances is excited, or the normal cells of the body are stimulated in such a way that they secrete the protective substance," and produces evidence of their insufficiency.

He prefers to think, "that the protective substance originates directly from the toxin, or is indeed an ingredient of its complex composition." In support of this he argues that the degree of protection artificially produced in an animal is proportional to the total quantity of toxin or venom introduced, rather than to the amount of reaction produced in the animal.

This leads up to the following suggestive passage:

"The question is not only of scientific interest, but it has also a practical bearing. The mechanism of the immunising substance is attended by much difficulty. A satisfactory antitoxin can rarely be obtained, and a tedious process, extending over several months, has been followed. And even when such a serum is obtained, so long a period of months, the immunising action of yellow fever is relative to slighter poisons, and the nearest approach to a satisfactory protecting serum

for the purpose of making injections of serum, and the fact that the serum is not only effective in the treatment of the disease, but also in the prevention of it, is a fact which has been brought to the attention of the public by the fact that the serum is now being used in the treatment of the disease, and also in the prevention of it.

THE SERUM TREATMENT OF TETANUS

The logical outcome of the toxic origin of tetanus is its treatment by antitoxins or antitoxins. Until lately this was only possible in the few well-known poison cases dealt with in the laboratory; the new antitoxins will consist of various antitoxins.

A few examples of the efficacy of some of these serums are given below.

A dose considerably above the minimum lethal dose of the toxin of tetanus is administered to an animal. Several hours after the administration, when symptoms of tetanus had manifested themselves, the antitoxin of tetanus is injected under the skin, and in a short time afterwards the symptoms of the disease disappear and the animal recovers.

Again with reference to serpent's venom "when this venom in lethal quantity is mixed in a test tube with a small quantity of antivenom, the venom almost instantly loses its toxic power. Further, if the smallest quantity of antivenom required to produce this change after contact for a definite time with a lethal quantity of venom be determined, it will be found that if the time of contact is lessened, this quantity of antivenom is no longer able to remove the toxicity of so large a quantity of venom. When, again, venom is injected under the skin of an animal at the same time as, but in a different position from, the antivenom, the quantity of the latter required to prevent death is for the same dose of venom about twelve times larger than when the two substances have been mixed together before they were injected. Such distinctions are difficult of explanation otherwise than by supposing that a combination, chemical or mechanical, is effected between the antivenom and the venom; for they indicate that when the conditions are the more favourable for ensuring contact between the antitoxin and the toxin the antidotal action is more powerful than when the conditions are less favourable for this contact."

Professor Frazer has the highest hopes of the future of certain therapeutics.

"Diphtheria," he says, "has had its case mortality from 70 per cent. to 80 per cent., or, according to another estimation, from 40 per cent. to 60 per cent.; hydrophobia has been so far brought under therapeutic control, by means which have not as yet been developed to their full efficiency, that its mortality has shrunk at least from 16 to 1 per cent.; the progress of diphtheria has been deprived of much of its gloomy overshadowing by the cure of pharyngitis, of tonsillitis, of erysipelas, and of septicaemia by the use of being realised; a complete demonstration of the value of the power of antitoxins is seen in the prevention of the toxic and fatal effects of tetanus; and the experiments have been made which have established the complete and perfect efficacy of the antitoxins in the treatment of the disease, and the fact that the antitoxins are small pox."

The fact that the antitoxins are small pox is a fact which has been brought to the attention of the public by the fact that the serum is now being used in the treatment of the disease, and also in the prevention of it.

**THE TEACHING OF SURGERY IN THE
CALCUTTA MEDICAL COLLEGE.**

THE announcement in the Government Gazette, that Professor JOSEPH O'BRIEN, M.D.B.S.I. and F.R.C.S. Edin, Lieutenant-Colonel, I.M.S. has retired from his appointment as Professor of Surgery in the Calcutta Medical College and as First Surgeon to the Calcutta Medical College Hospital, is a fitting opportunity for raising a discussion on the subject of his successor in the important office of Teacher of Surgery in the Calcutta University. That the College Hospital as a clinical institution, that its operation theatre as an arena for modern operative aseptic surgery, are behind the times, are facts too transparent to be denied. That modern surgery, either in principle or in art, is not taught in Calcutta as it should be taught, no one who has recently visited the hospitals of Great Britain, America or Europe, will hesitate to question for a single moment. Calcutta, in the matter of surgical teaching, is almost two whole decades in the background as compared with the smallest and most insignificant London hospital. Viewed from the light of experience during the past ten years of stagnation, the rapid advance of surgical teaching every where outside of India, reflects the gravest censure upon the educational agencies of this country. For nearly twenty years, surgery both in art and in science, has been presented to our thousands of Indian students in a more slipshod fashion. The cause of this discredit of which is not far to seek. Appointments have been given to men without the necessary appointments. But it is, that operative teaching have found their best surgeons of death from their ill health but they have lost an efficient and clever hand who were the very men who were teaching the surgery that they were to die. The result of this is that the surgery that is taught in Calcutta is a mere shadow of the surgery that is taught in the hospitals of the West. The result of this is that the surgery that is taught in Calcutta is a mere shadow of the surgery that is taught in the hospitals of the West. The result of this is that the surgery that is taught in Calcutta is a mere shadow of the surgery that is taught in the hospitals of the West.

where the students are not only taught every aspect of the anatomy of the body, but the College Hospital, an excellent place for observation, as teaching is the requirement of these other hospitals. The staff of surgery during the past few years consisted of two surgeons who were not even his assistants, while dissections could not be credited to their manipulation. Students and teachers were wasting because the teachers had no part in their official work, the best portion of their practice being being captured with private practice. Hence the important neglect of surgical education in our medical colleges. At the present time we feel that a very significant and vigorous protest ought to be made against the appointment of any but a skilled anatomist and an accomplished surgeon as well as an experienced surgical teacher in all the surgery caused by the retirement of Dr. JOSEPH C. MURRAY. In no respect on the otherwise excellent qualifications of Ernest Joseph E. D. MURRAY, who though an excellent civil service officer, has no pretensions either from academic qualifications, anatomical or surgical training, or special scientific experience to being considered a fit occupant for the post of Professor of Surgery in the Calcutta University, and First Surgeon to the Calcutta Medical College Hospital.

Dr. MURRAY qualified M.B., C.M. Ed. in 1878. We do not find that he possesses any special surgical qualification, nor are we aware that he has interested himself in the study of anatomy, nor in the acquisition of any special knowledge of modern surgery by undergoing any recent course in obtaining such a diploma as the Fellowship to the Royal College of Surgeons. In Great Britain the possession of the Diploma of Fellowship is *a sine qua non* for admission to a surgical appointment. In India things are different, for we find the Professorship of Medicine in an Indian University, filled by a comparatively junior officer, who has no higher academic qualifications than M.B.C.S. England and L.S.A. London, acquired in 1878. Now we find the chair of surgery to be filled by a gentleman who can in no way claim to be either a first class surgeon or a surgical anatomist.

We have no desire to personally attack any officer of the Indian Medical Service, nor have we intention to identify individuals with the object of ungenerously placing them in a pillory, but we feel that the important responsibilities of medical education in India are being sacrificed or sacrificed to the harmful and degrading influences of personal interest and nepotism. It is extremely absurditable to those in authority, that the claims of long service and seniority should be made to govern the disposal of collegiate appointments, when nothing but scholarly merit and exceptional professional ability should be the sole controlling criterion of fitness for such promotion. It is time the Indian Government exercised their right to exclude from institutions destined to them, teachers who see so glaringly white for their work. We raise this timely protest against the installation of one not a really skilled anatomist and an experienced competent surgeon into the position of Professor of Surgery at the Calcutta Medical College and First Surgeon to the Calcutta Hospital and General Dispensary, and we beg to state our conviction of its importance if it were given the place of existing appointment to Dr. NEWMAN as mentioned above will continue to export the interests of the Government till a radical change be made, not only in the staff and the interests of the medical students and the general reputation of the Calcutta Medical College and Hospital, but also in the character and public value of the institution itself.

The undersigned begs to assure you that he has signed the accompanying letter of his own free volition without

COMMENTS AND NEWS.

THE INDIAN MEDICAL RECORD AS A WEEKLY JOURNAL.

INDIA is without a weekly medical journal. For twenty-five years, *The Indian Medical Record* struggled along as it continues to struggle on still, as a Government organ, supported and paid for by State money, in other words by the taxpayers of a country unwilling to countenance its existence or to justify its support with its spontaneous contributions. The *Record* began as a monthly a quarter of a century ago, and continued as such. Were the State feeding bottle withdrawn from this monthly print, it would collapse in an instant. We state these facts to emphasise the injustice of the Government of India and of the Indian Medical Department which tolerate such a one-sided, unnecessary and uncalled for form of philanthropy. We say uncalled for, because an independent journal like the *Record* has, within nine years, won the support of the whole medical profession of the country, and has not only gone through the struggle for existence with the present position of financial success, but with the security of still greater success in the future, and all this without a brass farthing of assistance from the Government.

The *Record* was launched on the 1st of January 1890 as a Monthly, on 1st of January 1892, it was developed into a Fortnightly, and we hope to convert the *RECORD* into a WEEKLY on the 1st of January 1899. We commend this proposal to our readers, and we will be thankful to learn their wishes in this matter, before we launch upon an enterprise which will just double our expenses and our labour. We are perfectly prepared to face our share of the heavy responsibility which this change involves, and we desire to know whether our readers are as equally prepared for their portion of the monetary enhancement of their subscriptions, as the conversion of the *Record* into a weekly will involve twice the present rates, to be paid half yearly.

In view of this project, we now ask every reader of the *Record* to send the Manager of this journal a post card, without delay, stating whether or not he or she would like to see the *Record* become a weekly paper from the 1st January 1899.

SOIL AS A FACTOR IN THE SPREAD OF CERTAIN DISEASES.*

DR. JOHN ROBERTSON begins his paper which deals chiefly with the distribution of Typhoid fever in England, with a few suggestive remarks dealing with the subject generally. These remarks it may be well to repeat, as it appears to us especially important that the opinions expressed therein should not be lost sight of in India.

"During the past few years," he tells us, "renewed interest has been taken by sanitarians in the subject of soils as a factor in the production and spread of certain diseases."

DISTRIBUTION OF THE TYPHOID SOIL.

It is perhaps necessary to state at the outset that the term soil is used in the sense of a medium for the growth of organisms. It therefore includes the surface of a paved court or street, equally with the soil of a grain field, and a privy midden equally with the silt in and around a sewer or drain.

BACTERIOLOGY OF SURFACE SOILS.

It has of course long been well known that surface soils contain a very large number of micro-organisms of different species. It has been found, too, that the number varies very

* Paper read before the British Medical Association at Edinburgh.

much under different conditions, as also the rate of spread of these organisms. While the soil is moist, and the conditions which favour the growth of different organisms, it will be a subject which requires further investigation. It will be roughly stated that there are a larger number in made soils than in virgin soils. The number varies, too, with the amount of certain organic matters in the soil.

The largest number is found not at the surface, but at a distance of 12 to 24 inches below the surface. An interesting point, too, is that the number of organisms in undisturbed soils rapidly diminishes at a depth of 3 to 4 feet from the surface.

In some experiments which Dr. MATTIAND GIBSON and I carried out, we found that in the case of the typhoid organisms planted at a depth, there was an undoubted tendency to grow upwards to the surface rather than downwards. This appears to be quite distinct from the upward diffusion which has been frequently noted in the case of *B. anthrax* by means of earth worms. I believe that this tendency to upward growth has a most important bearing on the spread of disease by soils. In my own experiments I found that during the winter months organisms disappeared from the surface soil long before they had disappeared from the subjacent strata, and from these experiments I was led to believe that the deeper layers acted as a sort of shelter during the winter months from which the organism sallied forth to the surface during the warmer months.

CLASSIFICATION OF SOIL INFECTIONS.

Diseases which may be due to specifically contaminated soils in temperate climates may be, roughly, divided into two groups: (a) Those in which the specific organisms have a general or wide distribution. (b) Those in which the organisms have a local distribution.

It would appear that tetanus, malignant oedema, and the group of pyogenic diseases are examples of diseases due to group (a). Typhoid fever, epidemic diarrhoea, cholera, swine fever, and anthrax are diseases belonging to group (b). Such diseases as tuberculosis, leprosy, epidemic pneumonia, glanders, rabies, scarlet fever, etc., appear not to be propagated to any extent by growth in soil, whilst dust plays a most important part in their diffusion.

I desire particularly to draw attention to certain features of group (b) that is, those in which the organisms appear to have a local distribution, and I will take typhoid fever as a type of this group.

THE DISTRIBUTION OF TYPHOID FEVER.

DR. ROBERTSON illustrated the distribution of typhoid fever in England by a series of five quinquennial maps covering the period from 1871 to 1896.

The examination of this series shows that typhoid fever mortality is high in certain districts with the utmost regularity, while with an equal regularity it is low in other districts.

These five maps show the counties in which the mortality was 10 per cent. above that for the whole of England, and it is remarkable how closely they correspond from one five year period to another.

The endemic areas of typhoid are almost always the same, in other words the disease is almost connected with certain conditions of soil.

THE TYPHOID BACTERIUM IN THE SOIL.

DR. ROBERTSON cited certain experiments of his, a summary of which was given in the *Record* for May '98.

TYPHOID FEVER AND FERTILISERS.

On this subject he says:

My own experience in the investigation of the cause of nearly 2,000 cases of cholera from typhoid fever goes to

showing a mortality of 10 per cent. of all the cases with epidemic disease direct infection, and in another case a third being infected from the patient. This I believe is a larger percentage than is usually stated in these cases. Then, however, epidemic disease accounts for the incidence of typhoid fever in a certain relatively small proportion of cases. I believe that the water carriage of typhoid fever is a very important subject, but at the same time I think that the amount of attention it has received has to a large extent put out of count the relatively much more important subject of dust and filthborne typhoid. In my experience certainly over 90 per cent. of cases of typhoid fever in town districts cannot be accounted for by direct infection or by water or milk carriage of the infection.

SUBSOIL WATER AND TYPHOID.

Another factor which in my small experience appears to operate is that of ground water level. I have not noticed any relationship between the rise and fall of the ground water and the prevalence of typhoid fever similar to that which has been so ably described by VON FETTERKOFFER; but all my observations show that areas, where the ground water level is near the surface, are more liable to endemic typhoid fever than are areas where the ground water level is a low one during the summer months. This was the case at St. Helena in the areas affected. It is said to be so also in Dublin and many other towns where typhoid fever is specially prevalent, and it brings us back to one of the remedies suggested many years ago of "deep draining areas where typhoid fever is specially prevalent." It by no means follows that areas at a high level have a low ground water level, and it is questionable in areas of stiff clay whether deep draining would have the desired result.

Dr. ROBERTSON is inclined to attach a considerable amount of importance to the influence of subsoil water in the demarcation of the endemic areas, though he also thinks that local customs, in the arrangement and structure of dwellings together with local differences in the habits of the people may have some effect, though as he remarks, there are factors always difficult to estimate.

DUST AND DISEASE.

He feels certain that dust, under certain conditions, is the chief agency in the transference of the poison from the soil to the subject.

"I am now entitled to say," he remarks, "that dust is a very frequent means of spreading soil diseases."

The reason why Dr. ROBERTSON takes typhoid fever as an illustration of his thesis is, he tells us because "we have in it a well marked organism on the one hand, and a valuable series of statistics of the disease on the other."

It is only where accurate statistics of disease are available that inquiries of this kind can be carried out satisfactorily; and it is chiefly owing to the valuable series of statistics, due to accuracy of diagnosis, notification and registration in England, that so much advance has been made in recent years in our knowledge of the infectious diseases.

The northwestern of the greater part of Indian statistics seems to be impossible to carry them out in this country.

SURFACE WELLS AS A SOURCE OF

481 (1907) "WHERE TYPHOID"

Dr. W. H. ROBERTSON, in his paper, "Typhoid fever," published in the Indian Medical Record, 1907, p. 291, has shown that in the Indian subcontinent, the water supply is a very important factor in the spread of typhoid fever.

Dr. ROBERTSON, in the following table, classifies the wells drawn up by the Indian Medical Commission, and generally adopted.

Wholesome	1 Spring water	Very Palatable.
	2 Deep well water	
	3 Upland surface water	
Suspicious	4 Stagnant rain water	Indisputably Palatable.
	5 Surface water from polluted land	
Dangerous	6 River water to which sewage gases ascend	Palatable.
	7 Shallow well water	

Overlooking this Dr. CAMERON says, "I hold, however, that surface well water when, that is, it is reasonably safeguarded, ought to be placed third, or at least immediately after upland surface water, and that its proper position is in the "wholesome," not in the "suspicious," much less in the "dangerous" group.

Talking of the gradual substitution of gravitation for well water, he says: "The main purpose of my paper is to ask whether this drastic, and in most cases very costly, change is altogether reasonable, more particularly when, as in many instances, gravitation schemes are forced on unwilling and impoverished communities." Indian administrators please note!

He considers it a libel to put down surface wells as inferior to and more dangerous than surface water from cultivated land.

The essential difference between surface well water and rain water as it runs off the surface of the ground is that the former, percolating slowly through the soil, has undergone filtration more or less prolonged, the latter none at all, and there can be no question as to the universal value of this natural filtration in purifying even the filthiest surface waters.

This is strongly insisted upon by Dr. VIVIAN POORE, that intrepid champion of surface wells.

TYPHOID FEVER AND SURFACE WELLS.

He alludes to the danger of ploughing up and manuring the soil about surface wells, or over the pipes carrying water from such wells and relates two cases where typhoid fever was caused in this way. He continues.

The only other outbreaks of typhoid fever I have been able to trace to surface wells occurred in the case of one or two, and there were so situated in relation to dwellings and drains, so defectively constructed, and so absolutely unprotected from slop water and filth thrown over them, that crude sewage could not help gaining a direct entrance.

In no single instance have I been able to trace typhoid fever to any surface well situated in a decently clean locality.

THE PROTECTION OF SHALLOW WELLS.

My experience of surface wells during the last four or five years has led me to think that a most important aspect of water supply, that, namely, of the subsoil, has been unduly neglected.

Whence this unreasoning distrust of surface wells, this somewhat blind confidence in gravitation wells? the answer given is that more attention is bestowed upon gravitation water.

"Yet it is not uncommon," he says, "to find surface wells yielding pure water though unattended and surrounded by every kind of abomination."

The reason is that they are surrounded with ground which in spite of appearances still retains its filtering and purifying properties of efficient well water.

It is this that has led to the neglect of the surface well problem. I have no great faith in relying on surface wells. They

THE OLD ORDER CHANGETH

The Medical Council for August credits the following to Life ...

"When is your mother, Johnnie?"

"Playing golf."

"And your aunt?"

"She's out on her wheel."

"And your sister?"

"She's training for the football game."

"Then I'll see your father, please."

"He can't come down now. He is upstairs giving the baby a bath."

THE WELSH BAPTIST MEDICAL MISSION.

The medical centre of the Welsh Baptist Mission, Shillong has been transferred from Ohjna to Lailankote on the Nongkham heights above the station; a place celebrated for sterile group of dreddical cronelechs. Hongowicah, at the old station, had been the headquarters of the mission for nearly twenty years, but the new place is sheltered from the inclemency of the monsoon, and is more accessible from all parts of the hills, besides affording views a great deal more picturesque than the bleak and now shattered precipices amid which it stood.

THE ETHICS OF LOW FEES.

To take a small fee, because the patient cannot afford a large one, is to set up to the true principle of the profession and to keep up, in its strict form, the honorarium which the fee professes to be. To charge a low fee, in order to attract patients, is a suicidal policy. It degrades the practitioner who does it to the level of a huckster, and it pauperizes the patient to whom the charge is made, and leads him to put a purely commercial estimate upon the services rendered.

THE DUTY OF A UNIVERSITY.

Professor Hurley defined the duties of a university as "a corporation which has charge of the interests of knowledge as such and the business of which is to transmit knowledge to the requirements of its members, to increase knowledge by their investigations, to diffuse knowledge by their teaching, and last, but not least, to generate respect for knowledge among their fellow men by their personal example and influence." ...

The Madras Government considers that ...

The Indian Medical Service Dinner took place on the 19th September at the United Service Club, Simla, Surgeon-General Harvey presiding. The only guest was General Collins. This was the last gathering at which medical titles were used, as the new warrant, giving combatant rank to members of the Indian Medical Service arrived that day.

It has recently been decided by the Government of India in supersession of all previous orders, that for all officers, Civil, Military or Naval, whether in Civil or Military employ and for purposes of retirement, the fifty-fifth birthday is to be reckoned as a non-working day, and that an officer must retire on revert, or cease to be on leave (as the case may be), with effect from and including his fifty-fifth birthday.

As gradually the truth leaks out, says the *Philadelphia Polyclinic*, the members of the medical profession are becoming more and more convinced that the neglect and incompetency from which the sick and wounded of the United States army have suffered, is to be charged upon the War Department and a commanding general, and not upon medical officers, high or low.

Surgeon-Colonel B. Franklin, C. I. M., has been permitted by the Secretary of State to reckon service in the appointment of Surgeon to the Viceroy, towards the additional pension of £250 per annum granted to Administrative Medical Officers, from the date on which he was promoted Surgeon-Colonel.

Ten more medical officers are to be brought out from England shortly, with the rank of Temporary Civil Surgeon, to meet the demand which at present exists on account of the threatened visitation of plague. What about medical men who are on the spot and who are qualified and willing to do the work?

We learn from the *Gazette medicale de Paris* for July 16th, which cites as its authority the *Dictionnaire encyclopedique des sciences medicales* that no fewer than thirty-eight physicians have been elevated by the Catholic Church to the dignity of sainthood. All of them practised without gain and are credited with some miracles.

We hear on good authority that an official practitioner in Calcutta is doing a round of "cases" this morning for private patients! He has no time to "attend" work to do for his "official" duty, as he says so little about doing it, that he is long of the "top" of his patients' heads.

We are glad to be able to mention that a ...

The fact that the woman was pregnant, and that she had been pregnant, is a fact which cannot be denied, and which is the basis of the whole case.

On the Sunday, the 15th March, when Dr. MELOCH had been examined, every one agreed, and the widow admitted that the size of the abdomen diminished. What had happened? We cannot say, but it is certain that the woman herself believed that her pregnancy had terminated, for there can be no doubt that she knew she was pregnant considering that she had several times been pregnant before, and that she was far from the menopause. Her age was only 30 years.

Finally Dr. MELOCH is found fault with for not having recognised the existing pregnancy.

In his report, he says that he neither heard the sound of the fetal heart, nor perceived the active movements of the foetus, nor found ballotement.

The diagnosis of pregnancy is sometimes difficult, and may be difficult at any period of its course; doctors, surgeons, and midwives the most eminent make or may make mistakes which appear inconceivable.

Dr. MELOCH looked for the usual signs of pregnancy and failed to find them. The heart sounds are scarcely perceptible in the first half of pregnancy.

The absence of movement might have been due to diminished vitality in the foetus resulting from the hemorrhage of the 15th March.

It is a question if the Liquor Amni did not come away at the same time and prevent ballotement.

Again it is to be remarked that there is no certainty as to the period of gestation at which the woman had arrived, for the foetus was neither measured nor weighed. We have said that Dr. MELOCH looked for the usual signs of pregnancy, and we cannot admit that the chemical analysis of the blood provides a certain means of diagnosing either pregnancy or accouchement, as is stated in the following passage.

That with regard to examinations made on the 18th and 20th March the expert neglected to submit the blood to a chemical analysis, while its composition, according to all authors who have devoted themselves to legal medicine, one of the most certain indications of accouchement.

What blood is here referred to? Is it the blood that flows from the genital tract or is it the blood that the expert should have extracted from a vein? In either case from the medico-legal point of view the answer is the same? No medical jurist will admit that the chemical analysis of the blood can be utilized for the diagnosis of pregnancy. And no one would seek in such an analysis for one of the most certain indications of delivery.

Since AUDRAL and GAVARRETT's work on the subject, it is well known that much attention has been paid to the chemical analysis of the blood of pregnant women, the subject however is one whose proper place is the laboratory, and it can serve as a basis neither for a clinical diagnosis nor for a medico-legal diagnosis. FOURDRE indeed says that it is possible to distinguish between the blood of accouchement, the blood of menstruation, the blood from a wound and the blood from an animal in a state of stimulation. But there is nothing about chemical analysis.

Finally the medico-legal society of France, surprised like ourselves at this portion of the judgement of the Court of Saint-Nazaire, has devoted itself to this question at its meetings of 10th May and the 14th June 1897 and has unanimously arrived at the following conclusion.

"The Medico-Legal Society expresses the opinion, contrary to what is stated in the Judgement of the Court of Saint-Nazaire, that the chemical analysis of the blood yields no evidence upon which we can affirm the existence of pregnancy or of recent delivery."

Consequently we the undersigned are of opinion —

(1) That Dr. MELOCH's mistake, if indeed there was any mistake cannot be held to amount to an error, an imprudence or negligence.

(2) That the opinion of the Court of Saint-Nazaire cannot be accepted. Nantes, 10th July 1897.

This consultation was submitted to **PAUL BROUARDEL** for his approval, he wrote as follows:—

"I the undersigned, **PAUL BROUARDEL**, Head of the Faculty of Medicine of Paris having perused the report made by

Doctor JULES MELOCH, **Magistrate**, **Expert**, **Accused**, in the case of **BRILL, vs. MELOCH**, and having examined the proceedings of the Court, appears without reserve at the contents of the report and of its conclusions.

(1) In my opinion Dr. MELOCH, after examining the woman, if he was deceived in his diagnosis, certainly, and all that was in his power to avoid mistake.

(2) The opinion expressed by the Court of Saint-Nazaire is opposed to all we know of the methods of diagnosing pregnancy. 17th July, 1897.

Furnished with these opinions Dr. MELOCH entered an appeal and the case came before the Court of Appeal at Rennes, Presided over by M. ADAMS: on the 2nd June 1898. The Court gave the following judgement.

Considering that on the 18th March 1896, in the Commune of Campbon, Dr. MELOCH was requisitioned by the magistrate to visit the widow named **BILLY**, charged with suppressing an infant, "to see if this woman had been recently delivered of a living child or if the sexual organs presented signs of an abortion" and that having fulfilled the task the expert informed the magistrate, "that he had found traces of recent delivery, but that not having with him the necessary instruments it would be necessary to make a more complete examination at Saint-Nazaire" and that being asked to say if his observations pointed to a strong probability of delivery he answered in the affirmative.

Considering that on the 20th March, at the prison in Saint-Nazaire he again visited the widow, that from the report submitted by him on the 1st April, it appears that the symptoms found did not prevent him to state definitely that the woman had been recently delivered, that the symptoms provided a strong presumption in favour of delivery, and that they showed the necessity of following their progress to see if the milk disappeared, if the uterus underwent normal sub-involution, but that on the 23rd May the magistrate was informed by the prison warden that on that day at 6 A.M. the woman had given birth to a child at five months, which lived till 6 30 A.M.

Considering that on the 18th March, when Dr. MELOCH was visiting the accused, she said that she had had on Sunday the 15th a large discharge of blood mixed with clots, that nothing had come away at all resembling a child, that she had menstruated regularly and that she had not been pregnant.

Considering that it is notorious that the diagnosis is always much more difficult in a multipara than in a primipara, and that the Court is not in a position to pronounce with entire certitude that Dr. MELOCH has wrongly estimated the value of a number of symptoms, which according to the highest medical authorities, furnish a strong probability of recent delivery, and that he was guilty of negligence in not employing a stethoscope to find the heart sounds or in not making a microscopical examination of the blood.

Considering that according to the woman's own statement she had lost a large quantity of blood on the 15th March, we must recognise that the duty confided to Dr. MELOCH was a particularly delicate one, and that he acted prudently in not stating positively that the woman had been recently delivered, either after the examination of the 18th or of the 20th March.

Considering further that before the order for the arrest of the accused was issued, all the witnesses examined on oath before the magistrate had disposed to the facts in the most solemn manner, that the inquiry in view of the abdomen had been so marked that it had formed a common subject of remark throughout the whole place since the end of January.

Two young men affirmed that on the 18th February in an inn she had asked them if a woman who was 4 or 5 months' pregnant could bring on an abortion by the use of herbs (rue). On the evening of the 18th March, she had sent one of her children to tell her mother that she was ill, her mother had gone to her and found her confined to bed, she passed the night in the house, and the following morning she had been seen washing a woman's chemise and two shirts which were stained with blood from top to bottom. Considering that under the circumstances it is not certain that the opinion expressed by Dr. MELOCH, was the cause of the widow's

and that accordingly this judgment must be subject to the responsibility of a judicial officer of the rank of a magistrate.

For these reasons the Court supports the appeal. Subject to the demands of the widow RIZZY, and releases Dr. KINQUEEN from the judgment passed against him.

Thus this unfortunate matter terminated, and the whole medical profession has come to facilitate itself on the result arrived at by the Court of Review.

The formal conclusion to be drawn from this judgment is, that the medical expert who makes a mistake is no more responsible for it, than the magistrate who orders the arrest of an accused person whom he is obliged to place at liberty some days afterwards for want of proof, because his innocence has been established.

The report made in a case by the medical jurist has only a relative value, it is furnished to the magistrate who desires information upon a special point of which he is ignorant, he is not bound to accept its conclusion, but if he does accept them, it is he who takes the entire responsibility. The expert in his report never recommends the arrest of the accused person whom he has examined, for even if his report is favorable to the accused, the magistrate can still order the arrest if he can elsewhere obtain sufficient evidence.

The Court of Appeal in a recent case, where it was a question of experts in hand-writing, has clearly laid down the manner in which the report should be considered by the magistrate.

The following paragraph occurs in this judgment —

"Considering that, undoubtedly experts are useful auxiliaries to justice, but that their mission consists in making material statements, and in giving their advice in a clear manner, on the questions which are submitted to them, that their opinion which may always be disputed by the litigants, should not be binding upon the magistrate and that their reports should not have an official sanction."

The situation then is quite clear. The medical expert accepts no responsibility in the report which he places at the disposition of the Court, even if his conclusion is erroneous, always provided that his statements have been made in good faith.

If he has knowingly stated facts contrary to the truth by fraud malice, or with intent to deceive his case comes within the jurisdiction of the Court and he is treated the same as any one else.

In conclusion there remains one point which must be approached delicately. For some years, especially since the daily press has on all sides taken to publishing medical theories, and therapeutic methods, almost as soon as they are discovered, the public, kept up to date as regards the progress of the science, wrongly imagines that it is in a position to discuss the subject.

Unfortunately magistrates forgetting that in such matters they are incompetent, enter too readily into medical subjects and discuss them in the preamble to their judgements.

And yet the relations that should exist between magistrate and doctors, and the way in which a case relating to medical responsibility should be considered and discussed before a Court, has been clearly laid down 60 years ago by the Procurer General DUPIN, who said —

"In cases of this kind, it is not a question of whether the treatment was well or ill-advised, whether it was beneficial or injurious, if another course would have been preferable, whether such an operation was indispensable or not, whether it was prudent or not to attempt it, whether with such and such an instrument, or done in such and such manner it might not have been more successful."

"There are questions of science, which must be discussed between doctors which do not involve civil responsibility and are not subject to the examination of the Court."

It seems that magistrates as well as doctors have everything to gain by keeping within the bounds assigned to them by DUPIN. Medical discussion the legitimate difference between Hippocrates and Galien, and magistrates should not intervene, otherwise their judgements will be liable to be erroneous and insecure and to cast discredit upon the learning of the Legal Profession.

Current Medical Literature.

CONVULSIONS.

Convulsions in Infants and Children.

Requires prompt and efficient treatment as they are accompanied by more or less brain hyperemia, asphyxia, and congestion of the lungs and various internal organs, and if not immediately relieved may end in death. Apply a hot pack at once of 75° to 80° F. water round the child's body, apply ether or chloroform to its nose and give it a large enema of 95° to 100° F. water. While the child is thus resting first take its temperature (if it be subnormal use stimulants) and then looking into the history of the case examine its lungs, heart and urine and search the nose and ears for foreign bodies &c and the penis for phimosis. The hot enema which may later on be followed by cold injections of 50 to 65° F. relieves the heart, equalizes the circulation, dilates the peripheral vessels and unloads the bowels. If the face is flushed, while the hot pack will relieve capillary congestion and relaxing the superficial vessels expediting heat elimination. In all cases except shock apply cold to the head and if the temperature remain excessively high, follow the hot pack with a cold one and give what remedies the nature of the case requires. If the convulsions are excessive or unduly prolonged, give a hypoderm of $\frac{1}{4}$ or $\frac{1}{8}$ grain of morphine according as the babe is 6 months, 12 months or 3 years old and repeat in an hour or two, doubling the dose. In asphyxia use oxygen and if it is proper, in most cases, to give a purgative, as calomel, by the mouth, or if the constipation be obstinate 1 to 1 drop of croton oil may be given in glycerine or whiskey. A child who has convulsions, or a tendency for them to recur, must be kept absolutely quiet and fed in the simplest manner, altogether by fluids—for several days.—*Phil. Poly.*

Varieties of Diabetes Mellitus.

OWING to multiple etiologic factors the infinite varieties of this disease would be hard if not impossible, to classify properly and LEPINE shows that each case is constituted by several pathogenic elements of varying importance. Thus while gout in arthritic persons is associated with an intermittent but abundant glycosuria, comparatively benign, certain diseases of the pancreas may be followed by a rapid and dangerous diabetes. In some cases of diabetes the sugar may be lacking or be transformed into fat or be oxidized, while in other cases there is exaggerated elimination of nitrogen and some of the patients excrete enormous quantities of sugar after ingesting much meat. Then in pancreatic diabetes there is azoamyria and diminution of glycolytic ferment, fat formation and sugar production, whereas in the nervous variety there is azoamyria, exaggerated hepatic glycogenesis and diminution of glycolytic ferment, while the glycosuria is often quite moderate and may even disappear leaving behind a simple polyuria.—*Semi-Med.*

Alterations of Taste and Smell in Tabes.

KLIPFEL has made a study of the various alterations in the senses of smell and taste as they occur in tabes dorsalis. Contrary to the general idea that these symptoms are rare, the author finds that they are of common occurrence in cases of this disease, and may manifest themselves at a very early date, in regard to this they correspond to the other sensory symptoms, such as numbness, paresthesia and pains. At the same time the author has noticed the late occurrence of these symptoms in several cases. In these circumstances anosmia and agusia are observed, and as by this time the patient has, as a rule many other symptoms to absorb his attention, complete loss of smell may go unnoticed. Both these symptoms may appear suddenly and in association with bulbar symptoms. In other instances smell and taste merely show perversion and in an intermittent form, thus resembling crises. There may be for a day or so at a time peculiar earthy metallic, or bitter taste sensations appearing independently of meals, and lasting for about ten minutes or a quarter of an hour. In the same manner patients may complain of sour smells and odours of stale fish, vomited matter, etc.—*Brit. Med. Jour.*

Hot Water Treatment of Mycetozoma.

M. LAGHAÏE, in describing cases of mycetozoma met with in Algeria, was struck by the absence of any tendency to generalization, in which point it contrasts with actinomycosis.

of the skin and of the underlying tissues, and the possibility of more serious infection in the event of a wound, such as wounds being washed and dressed with antiseptic, and dressed too often at intervals when they should be left severely alone. The skin and soft parts about the wound or the pus formation, which (latter) are likely to tear granulations and damage epithelial growths. In further illustration of his theory of non-interference he shows (1) That in incised wounds, without much injury to the trophic nerves, but not healing by first intention, the capillaries begin to develop exceedingly fine and very delicate granulation tissue often accompanied with free suppuration which we might feel tempted to wipe or wash out, instead of leaving it alone. However gently done the merest touch provokes traumatism which develop exuberant granulations poorly supplied with blood vessels and the removal of the gauze covering tears off some of the granulations, but if left alone the pus will disintegrate itself and hasten the reparative process. (2) When the epithelium is shooting across a wound it is still more desirable to not meddle with the dressings as the slightest touch will damage this hyaline epithelium and by removing some of it retard the healing of the wound. (3) In peritoneal operations after evacuating the pus and inserting the drainage apparatus we are slowly tempted to wash out the wound with peroxide of hydrogen or some other antiseptic, because of the stench. If we do so we not only unnecessarily disturb the patient to whose safety rest is essential, but we also inflict new traumatism that induce hyper-leucocytosis and (often dangerous) reactive inflammations. Ignore the stench and let the colon bacilli increase in number. They will at first produce a very foul odour in the discharge but in 3 or 4 days the streptococci multiply so abundantly as to destroy all other bacteria, decrease the disagreeable odor and hasten repair. (4) Take burns of the second degree where blebs have formed and broken and an extensive surface has been denuded of creticle. The serum such an injury throws out is healthful and germicidal. Etherize the patient, open the blebs, cut away the dead tissues and skin, scrape the parts with an antiseptic solution and covering the denuded surface with strips of gutta serena tissue (changed once in 10 or 15 days) leave the rest to Nature with her serious exudations and suppurative processes. The patient does well, but change the dressings frequently, mop out the serum or wipe off the pus, and traumatism arises leading to sepsis with the risk of thrombi, necrosis of the duodenum and perforating ulcers.

Pseudoepastic Paralysis with Tremor.

Is a rare affection of uncertain pathology and Dr. O'NEIL tells how immediately after being struck on his head by the corner of a trap door, a heavy drinker, age 40, his face and limbs paralyzed and anesthetic, but did not lose consciousness. Speech and facial movements were completely recovered in 30 minutes, but though it took a good 4 months for the limbs to regain full power, curious tingling sensations persisted in the hands and the slightest excitement made his body tremble and shiver violently, while the deep reflexes were greatly augmented and the plantar and abdominal reflexes absent. His gait was spastic and high stepping. O'NEIL does not agree with the suggestion that this condition is either a functional disturbance or a toxicemic, nervous, condition, but rather to the traumatic lesion of the spinal cord or peripheral nerves in the brain.

Conservation and Gynecology. Choice of Routes Abdominal or Vaginal in Intra-uterine Surgery.

It being impossible to lay down a rule of thumb that such and such work should all be done in one particular way, Dr. CLAUDE CLEVELAND thinks each case must be judged on its own merits and each route will always have its advocates and its aims, though there are operations in the pelvis that cannot be done per vaginam—a route, however, is not always feasible, though naturally indicated. It is a mistake to say that as clean and thorough surgery cannot be done through the vagina as through abdominal section and the objection to vaginal hysterectomy or ovariectomy from the possible presence of adhesions is not of much moment, since ovarian cysts of the present day have not had time to acquire adhesions, and with cystic ovaries, small solid tumours of the ovaries, multilocular cysts of small size, broad-ligament cysts, dermoids whose rupture produces fatal peritonitis by reason of the dangerous fluid it contains, pus tubal, cystic fibroids, especially when low down, tuberculous conditions of the uterus and tubes, pyosalpinx, tube-ovarian abscesses, such as myofibroma, most polypoid growths and cancer of the uterus, are most easily, and most wisely removed per vaginam. Large myofibromata may also be removed through the vagina, but the operation is so very long and the danger from hemorrhage so great that abdominal hysterectomy becomes the safer and quicker course. So also with cellulitis and extra-uterine pregnancy: True conservatism should always be our guide in the treatment of disease and it more than often happens that an apparently hopelessly diseased uterus can be cured by curettage and drainage—even when the infection has been from gonorrhoea. If a cancerous uterus cannot be removed per vaginam it has reached a stage when operative interference is by no means justifiable. Always take the lower route when dealing with pus-tubal, dermoids, and pyosalpinx and never open the abdomen for the removal of such. Whenever possible to do so try to save the uterus and keep well in mind that it is rarely necessary to open the abdomen for the surgical treatment of those diseases of the pelvis that are due to infection.—*Med. Rec.*

Occurrence of Menstrual Secretion in the Fallopian Tubes of the Human Subject and its Significance.

FORMED the subject of a long series of investigations undertaken by C. J. BOYD, M.D., to prove whether the bloodstained mucus-like menstrual fluid, found in the lower portions of the Fallopian tubes during uterine menstruation, originates in the tubes or depends on backward regurgitation from the uterine cavity. He finds that this tubal secretion coincides with or precedes, but never succeeds the appearance of the menstrual flow externally, and that definite changes found in the Fallopian mucous membrane at that time float the theory of regurgitation from the womb. The occurrence of the Fallopian menstruation, he notes, has an important bearing on certain points in human pathology. For instance it may predispose to extra-uterine or tubal pregnancy by providing a surface on which the ovum, in its passage through the tube, may become grafted. It is likely that much of the pain of dysmenorrhoea is due to tubal cramps or to efforts to expel the functionally bloody mucus, especially in those cases in which the pathogenesis or coincides with the first day or two of the 'menstrual period.' It has an important bearing on certain signs of hamato-salpinx when pregnancy is absent and may also throw light (even in the absence of gonorrhoea or other infective processes) on certain cases of recurring local

perforation of the uterus, the instrument is removed, and the patient is kept in bed for a few days, and the wound is dressed with antiseptic.

Precautions in Septic Puerperal Cases.

It is the opinion of many leading obstetricians (as may be seen in the discussions of the Obstetrical Society) that without disinfection no more lapses of time will prevent conveyance of infection; and if thorough disinfection is carried out, it is not necessary for a doctor or midwife to discontinue practice for a longer time than that necessary for the disinfection. No lapses of time will sterilise a septic dress or syringe, nor will it change the habits of a woman who never was a nailbrush. On the other hand, if the midwife will burn her infectious garments and put on clean ones, will scrub her nails (if they are spotless, make a practice of boiling her syringe, catheter, etc., and of carrying about and using antiseptics, it is not needful that she should abstain from practice. This we believe, is the current teaching of those who are best qualified to form an opinion on the subject.—*Treatment.*

Perforation of Uterus by Sound and Curette.

ROSENFELD reports a case of unusual importance, as the injury was made plain to the naked eye by operation. The patient was 32, with flabby muscles, the last pregnancy ended 18 months before the operation, which was to cure complete rupture of the perineum and prolapsed uteri, from which she had long suffered. Before the operation, by PROCHOWNICK, a sound was passed cautiously into the uterus, and suddenly slipped in for over 5 inches; no pain followed. Next day PROCHOWNICK began by using a blunt curette. It also passed in suddenly over 6 inches, going into and beyond the uterine cavity. Partial amputation of the cervix was performed, as well as repair of the perineum. In the course of somewhat complicated incisions (MACKENRODT's operation) the body of the uterus was rotated into the vagina. The perforation lay in the posterior wall of the uterus, a little behind the fundus. It was slit-like, a quarter of an inch long, and its edges were almost clean cut. There was no evidence of peritoneal irritation, but a thimbleful of bloody serum, without clot, escaped from DOUGLAS's pouch. The edges of the wound were carefully united with catgut. No ill consequences seem to have followed. ROSENFELD calls attention to BRUTNER, COEBANT and ODEBRECHT's three cases of instrumental perforation of the uterus, all reported in the 1897 volume of the *Centralblatt für Gynäkologie*.

Hysterectomy.

One contends that abortion should be induced, if possible, when tumor in the lower segment do not rise out of the pelvis as the uterus enlarges. Submucous polyp may be removed when they are accessible. Subperitoneal growths can be disregarded unless they become impacted in the pelvis, undergo torsion of the pedicle or contract adhesions. Liberations of the tumor under anesthesia failing, the abdomen can be opened to separate adhesions or remove the tumor, not disturbing the uterus. Conservative myomectomy may be performed with the hope of subsequent normal labor. The indications for hysterectomy in cases of fibroid become more urgent if pregnancy occurs.—Dr. H. C. COE, in *Medical News*.

Physiology, Pathology and Treatment of the Placenta.

Stages in the Development of the Placenta.

HAHN reports a case of abortion at the fourth month, in which, on admission of the patient to HERMAN's clinic, a fetus twelve centimetres long had already been expelled. The thin cord was in the woman's vagina, and through the os, which was wide enough to admit a finger easily, a soft body as large as a walnut projected, and turned out to be a projecting flap of the placenta, bearing the nearly marginal insertion of the cord. It was remarked that the maternal side of the placenta was nearly as smooth as that on which the cord was attached, and this smoothness extended some distance higher up. HAHN points out that in this case there was a reflex placenta of considerable size, for the smooth thick, decidua investment which completely clothed the lower portion could, from its macroscopic appearance, its relation to the limiting oris, and the feeling to the touch above mentioned, only be regarded as decidua reflexa. The fact that the cord was inserted on the projecting reflex portion, and that the villous tissue exhibited most development about the insertion of the cord, HAHN considers a new proof of KELLMAN's theory, according to which the position of the placenta merely depends on the primitive insertion of the allantois on the chorion,—that is to say, what becomes later the insertion of the umbilical cord.—*Univ. Med. Mag.*

Olimacterium in Males.

In many males, there is manifestly a physiological-critical period about the beginning of their fifth decade. This change of life is one primarily associated with nutrition. The digestive and assimilative functions begin to slow down between 40 and 50 years of age, and the organism as a whole, undergoes a readjustment. If the digestion remain active while assimilation becomes less perfect, an increase of weight, due to accumulation of fat, takes place. It on the other hand, digestion is the first to fail, symptoms of dyspepsia, with associated loss of flesh, characterize the period of transition. It is in the athletic individuals of active muscular habit that the manifestations are most marked. A time arrives when lessened nutrition renders it impossible to maintain the normal activity of the muscular system. The eliminatory organs perform their function less perfectly, and the processes of dissimilation are hindered. The accumulation of the products of metabolic tissue change in the system, reduces the vitality of the subject and indisposes him to the routine amount of exercise. If the subject fail to grasp the significance of these sensations he renders himself liable to various functional disturbances which may culminate in organic disease of the organ or organs most exposed to the strain. Even if he yield to the pressure put upon him, it takes some time for the muscular and vascular systems to tone down to the reduced standard of vitality and during the period of adjustment he is apt to suffer from a variety of more or less distressing feelings; which not infrequently determine mental depression. The change is not unlike that holiday spent in active physical exercise. There is the same want of harmony between nutrition and muscular exertion, but in the waning adult, there is, of course the factor of increasing arterial rigidity and general loss of tone on the part of the tissues. The so-called "critical period" is only critical in so far as the readjustment of the organism to changing conditions is interfered with. Those who have always led a sedentary life are less subject to these disturbances than the more robust and actively disposed. Once the harmony of the functions has been restored the individ-

dead, and he comes to the same conclusion which are apt to make them "irregularly."—*Jour. Amer. Med. Assoc.*

Inoculation against Cholera and Typhoid Fever.

R. FRIEDMAN and MARK have investigated the employment of preserved inoculation material against these diseases for use in epidemics or in war. FRIEDMAN and KOLLE's method of immunising man against typhoid fever consists in injecting subcutaneously 3 mg. of an eighteen hours' old agar culture killed by an exposure to a temperature of 70° C. In this way the serum of the inoculated individual acquires the properties of the serum taken from a patient who has passed through an attack of typhoid fever. For the purposes of preservation the authors added 5 per cent. phenol or 50 per cent. glycerine. They found by experiment that the efficiency of the inoculation material was unimpaired by the phenol but was considerably diminished by the glycerine. In the same way they showed that cholera inoculation material may also be preserved for long periods by the addition of 0.5 per cent. phenol. FRIEDMAN and MARK then inoculated with this preserved material three laboratory attendants against typhoid, because they have on several occasions known of severe laboratory typhoid. The injections were made into the back. In a short time the temperature rose to 38° C., and there was headache and malaise. One of the attendants was well on the following day, whereas the other two after a restless night still had a temperature of 38° C., and showed some swelling and redness about the site of the injection. Twenty-four hours after the injection these symptoms began to abate, and the patients were well on the following day. Blood was taken from these attendants before and after the inoculation, and the serum showed marked immunising properties after the injections. Thus the authors conclude that both the cholera and typhoid inoculation material may be kept unimpaired for at least four to ten weeks by the addition of 0.5 per cent. carbolic acid.—*Brit. Med. Jour.*

Examination of the Sputum.

A. HOFFMANN draws attention to two kinds of cells which are differentiated by the eosin stain. (1) There is a cell about the size of the white blood cell which contains several small deeply-stained nuclei. HOFFMANN looks upon this as a polymorphous white cell. Such cells are seen in specimens of the blood from marked anemia, especially that occurring in chronic nephritis. (2) The other kind of cell is rarer but more striking. It shows a sharp outline and contains an area inside which is either unstained or only slightly stained. In this area there are several well-stained molecules of varying shape. Sometimes these molecules are so numerous as to fill the unstained area, but they mostly number from 2 to 5. These cells are larger than pus cells. The author found them most abundantly in whooping-cough, but they are also present in other diseases. They are most often found in the sputum of children. They are rarely seen where eosinophilic cells are present. In many forms of bronchitis, as well as in asthma, eosinophilic cells are found, and HOFFMANN would look upon what he terms "eosinophilic bronchitis" as an incomplete form of asthma. The second kind of cell described here is present in an acute bronchitis which has no relationship with asthma. Their origin is difficult to explain, but the author regards them as altered nuclei of the cylindrical epithelium of the bronchial tract.—*Brit. Med. Jour.*

PUBLIC AND PRIVATE LIFE AND THE PSYCHOLOGICAL STUDY OF THE HUMAN MIND.

In his psychological study of various forms of life affecting the human mind, Dr. WILLIAM W. ISKLAND maintains that the peculiar opportunities offered by a rapidly changing evolutionary nation form psychological monstrosities so wrapped up in themselves and their 'object' in view, that they are utterly apathetic to every one and everything else, as instanced by some of our proverbially self-made rich men who have developed a mania for money-making through stock speculations. Such persons soon lose all tastes for any civilised mode of entertaining one's self. The more they have the more they want. They have come to know but one enjoyment and have but one god, and there are more money-getting. Dr. P. O. RICHMOND supplements this with a curious tale of a commercial man who had neither Christian nor pagan philosophy sufficient to quietly accept success or suffer defeat. It was always either the stigma of victory or the mournful pitroch of defeat and calamity that sounded in his lair. Every serious loss was attended by as depressing an illness as every great gain by a fever due to too high exhilaration, and in the end a loss of a few thousand dollars which made no material difference in his affairs, for ever stilled his restless life.—*Pac. Med. Jour.*

Care of the Teeth.

The following directions, taken from *The British Journal of Dental Science*, are evidently written by a practical man.

"In addition to the use of a suitable tooth-brush and tooth-powder on the teeth, there is no practice which commends itself so highly as the use of a piece of silk thread. It will take the average person some time to become expert in handling it, but when this is attained, it will be acknowledged the best toothpick and beautifier of teeth in the world. Cut off from the reel a piece of silk about fifteen inches long, which thoroughly wax. With the thumbs and forefingers carry the waxed floss silk into each space between the teeth, the remaining three fingers of each hand being used to hold on to the ends of the silk firmly. The thumb and forefinger of each hand, as they hold the silk, should be kept but a very little farther apart than the width of the teeth between which the silk is to be passed. Thorough tension of the silk must be kept up at all times. For the eight teeth on the left side of the upper jaw, pass the silk over the end of the left-hand thumb and over the end of the right-hand forefinger. Thus the palm of the right hand and the back of the thumb of the left hand will be toward the face. Hold firmly, slide it between the teeth with a gliding motion; carry it well down between the necks of the teeth and the free edges of the gums, but not in such a manner as to wound the latter, the pressure being properly brought against the teeth, not against the gums. Before sliding the silk from between the teeth, the silk may be rapidly drawn backward and forward on the necks of the teeth, thus polishing and preserving these surfaces, and "raking out" any deposits of food or incipient tartar which may be there. The silk should be slid from between the teeth with the same tension as when it is introduced between them, otherwise it will tear when the teeth are very close together. If this rule be observed and the silk still tears, it indicates one of several conditions—a cavity of decay, a smile of tartar, or a sharp point or jagged edge of the tooth, any of which conditions should be corrected by a reliable dentist."

CAUSE OF DELAYED CONCEPTION

A BATHING puzzling class of cases for obstetricians is that of delayed conception. Dr. HEDDER, in the *Berlin Medical*, October 30, analyzed about 100 cases of primiparae labor in wives married for several years and relatively mature. He favors the third decade as the neglect proper to be included under the term of "maturity," or the *primiparae aetate* of the French writers. It appears that in a genuine uncomplicated case of delayed impregnation the advent of the menses is always found to have occurred late in youth. Out of 401 such cases, menstruation was retarded till 20 in 30, till 24 in 4, and till 25 in 1. As to the retarded first pregnancy such complications as abortion, ectopic gestation, twins and special anal mischief are relatively frequent. Above all, lightning labor is especially common, statistics even exceeding greens and *a priori* reasoning in this respect. In 12 out of 17, noted by Dr. KONIG, labor lasted from forty to fifty hours, the remaining labors being yet longer; one extended ninety hours. Feebleness of uterine contraction is absolute from first to last, and independent of any obstetrical combination. They also cause far more physical and mental exhaustion than the vigorous contractions of a young uterus, and at the same time are more painful. There are discrepancies in the "pains" seen in mature primiparae of the same age, probably homologous with the great variations in the age of menopause observed in otherwise normal women. The uterus may be older in one woman aged 35 than in another of the same age. The forceps and other obstetrical operations are often required in the mature. Most of the above facts are easily explained. The excess of male infants borne by mature primiparae (30 per cent.) is a less explicable phenomenon. HEDDER considers the predominance of male infants as a speciality of all primiparae, but RUMPS turns attention to the fact that in a family of children the predominance of males is commoner the further the mother is from her first menstrual period.—*Jour. Amer. Med. Assoc.*

Professional Secrecy in France.

THE *New York Medical Journal* records a legal decision in the French court of appeal which is of great interest professionally. According to article 878 of the French penal code, a physician is forbidden to reveal any secrets confided to him, or of which he becomes cognizant, in the exercise of his profession. A married woman, applying for a divorce from her husband, sought permission to introduce in evidence certain letters addressed to her by Dr. COMBES, who had attended her husband, to show the nature of his malady. The court commenced by laying down that the physician does not exceed the limits of his rights when he informs by letter the wife of a man whose husband he is attending of the cause and nature of his disease. But it adds that these letters must not be divulged, even by agreement between the sender and the recipient; as the obligation to professional secrecy imposed by the law does not permit of his consenting to their publication. This rule permits of no exception, and must be applied even where the applicant for divorce wishes to put them in evidence as proof of her wrong; for confidences which the interest of the patient can alone justify, must not, under any pretext, be used against him.

THERAPEUTIC AND PHARMACOLOGICAL Diet in the Treatment of Ischuria.

For a long time persons have urged that diet was the real remedy for ischuria. Yet when it was applied in certain cases, no better results were obtained. The ischuric symptoms remained. Occasionally the change from wheat to a grain diet, or the reverse, was followed by the subsidence of all desire for spirits. In a continuous drinker a general diet of both meats and grains appears to meet the demands of a disordered nutrition and semi-starved condition better than any special articles of food. In the ischuric cases an albuminous or proteid diet is often decidedly injurious. In some cases an intense craving for meat or for starchy foods precedes the drink paroxysm, which subsides when the craze breaks out. The intimate relation between foods and the drink paroxysm is very prominent in many cases.

In some cases excessive meat eating is associated with great irritability and sensitiveness of the brain and nervous system. The change of diet is followed by a great improvement of mental activity. It would appear from a study of many cases that so far no general rule can be found, and each case must be studied from the facts of its history. Thus, in some cases a meat diet is literally poisonous, and its removal is the first essential for a cure. Again, a grain or fruit diet is clearly injurious, and more rapid recovery follows a change. In all cases states of starvation and anti-intoxications exist, the removal of which is of equal importance to that of spirits. The study of the diet brings out many unsuspected causes, which require removal and treatment before a cure can be effected.—*Health.*

Electricity in Incontinence of Urine.

CAPRIATI records a case of involuntary enuresis successfully treated by means of the currents introduced into medicine by MONTOR, of New York. These are known as induced static currents, and are furnished by the oscillatory discharge of Leyden jars connected with an electrical machine. The patient is not insulated, but is connected with one of the jars, while the other is connected with earth. The intensity of the current is regulated by merely altering the distance between the jars. CAPRIATI's patient was a previously healthy man of 35, who was gradually attacked by weakness and wasting in the left leg, with club-foot and exaggerated knee-jerk on that side. There was no reaction of degeneration, but incontinence of urine was very troublesome. The author considered the symptoms to point to a limited lesion of the spinal cord in the lumbar region. At first galvanism was tried with the cathode over the dorso-lumbar spine, and the anode on the perineum; this was continued for ten minutes daily for more than 20 days without any benefit resulting. Endo-urethral faradisation (Guyon) was next adopted, but was so painful that it had to be abandoned after two sittings. Finally MONTOR's currents were used in conjunction with the spino-perineal galvanisation. Immediate relief followed, and after the treatment had been carried out every other day for two months, cure was complete as regards the incontinence. As galvanisation by itself had proved ineffectual, the credit must be given entirely to the method of static induction. It was extremely well borne when used in the manner laid down by Bordier. A sound, the end of which formed an electrode, was introduced into the urethra as far as the sphincter of the bladder, and its free end was attached by a chain to one of the Leyden jars; the machine was regulated to give 5 to 8 sparks a second, and with sitting lasted 5 minutes.—*Brit. Med. Jour.*

Uranium Nitrates in Diabetes Mellitus.

As all the soluble and absorbable salts of uranium (which are destructive to protoplasm, all living tissues and even the vitality of the blood) are violent insidious poisons for which there is no known antidote, their uses as medicine have not been much tested, since their introduction in 1874 in the treatment of diabetes; but FORTER notices that amongst the earliest symptoms of poisoning by these salts are (1) glycosuria, (2) gastro enteritis, (3) nephritis like that of scarlet fever, (4) hemorrhages into the heart and liver where death is escaped, (5) grave disturbances of nutrition and (6) excessive emaciation. Wherefore he thinks it is unsafe to begin with more than *one-sixth* of a grain of the nitrate three times daily.

J. W. DANIELS who has been most successful in treating *sic* cases of glycosuria with uranium nitrate in initial doses of 1 grain gradually raised to 12 grains three times daily, thinks that in uranium nitrate we have a drug markedly superior to any derivative of opium and of unequalled value in different cases of diabetes. In fact he declares it to be the most efficient remedy thus far brought forward, and the larger the doses (that can be borne) administered the more satisfactory and the quicker the resultant cure.—*Pract. Therap.*

Three American Drinks.**Raspberry Phosphate.**

Dilute phosphoric acid ... 20 drops
Syrup of raspberry, about ... 1½ oz.
Ice-cold soda-water to fill a tumbler.

Imbibed through a couple of straws, it tickles the palate and refreshes the thirsty soul.

A more substantial drink, which is much used between meals, is—

Egg Lemonade.

The juice of two lemons
Simple syrup, about ... 1½ oz.

Mix with one egg, beaten well up first; then add soda-water to fill tumbler.

This drink goes well upon hot days when the appetite is jaded. A few pieces of ice dropped in, of course, adds to the enjoyment of the draught.

Another drink largely consumed at the soda-fountain is—

Claret Cup.

Claret ... 2 oz.
The juice of one lemon
Simple syrup, about ... 1½ oz.
Soda-water to fill a tumbler

Add a few pieces of ice, and suck through a straw.—*C. D.*

Therapeutic Brevities.

1. BERHENS declares that in place of being a normal constituent of hope, Trimethylamine is the result of bacterial fermentation.—*Jour Chem. Soc.*

2. If women use themselves to it by bathing every day for 8 days before the period, DEPASSE says the cold bath during menstruation is a beneficial measure and HANZEL finds that cold salt-water baths facilitate the menstrual flow, prolong genital life and increase fecundity.—*Lancet-Clinic.*

3. Quinine murate dissolved in 90 parts of distilled water, is recommended by HOWE as an absolutely effective analgesic in all cases of acute catarrh.—*Pharm. Zeit.*

Correspondence.**MEDICAL ADVERTISING IN INDIA.**

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Advertising by medical men in India is becoming very common. Assistant Surgeons and even graduates of British Universities, (who ought to know better), are not ashamed to bring themselves into public notice by means of placards, which to say the least of it is a practice, totally disgraceful and too humiliating to the members of the profession, which is the noblest profession in the world. A graduate of a British University by so doing not only degrades himself in the eyes of the knowing public, but brings into disgrace his *alma mater*.

I think that the time has now come, and it is none too soon, when that great body the Indian Medical Association, should come to the rescue of the profession by bringing the defaulters to the notice of the university authorities and the General Medical Council of Great Britain, and by thus exposing them, uphold the honor and dignity of the medical profession.

Here is a copy of a placard which has been put up on all the principal roads and at all the public places in Lucknow. I also beg to enclose literal translation of an Urdu notice which has been freely circulated in the city.

Dr. M. S. VARIS, M.B., C.M., Edin.

Consulting Physician, and Surgeon. Consultation all Hours. Free, 9-11 A.M. Share Darvoza.

NOTICE.

Dr. SAYAD MAHOMED VARIS, Surgeon!

"Good news to thee O! heart, a Jesus like man has come!"
"Be it known to the seekers after bodily health, and to those in the clutches of deadly diseases, that the ARISTOTLE of the times, and GALEN of the universe, Dr. SAYAD MAHOMED VARIS, M.B., C.M., after learning the art of medicine and practising it in Great Britain, has come to this town (Lucknow). He studied for 6 or 7 years in modern Athens, viz., Edinburgh, which is the Capital of Scotland, and he obtained the Diploma of a Physician and Surgeon, and there for three years he established himself in practice and performed Christ-like miracles."

"It is our good fortune that he has established himself here. It is hoped that whosoever will apply to him for treatment, will fill his pockets with pearls of health. He lives close to Kaimur Bag near Share Darvoza, opposite the Telegraph Office, in house, No. 1. Patients can consult him all day."

Criticism is needless, we know what all this means.

There is another gentleman in Lucknow who is advertising himself extensively in the "Indian Advocate." He is an M.D., B.Sc., whether of a University in Great Britain or of a *bogus* American University is unknown. His name is Dr. BHAGWANDIN.

Here is another shocking case of medical advertising, cut from the Lahore Tribune of the 18th August 1898:—

MEDICAL NOTICE.

PUNJAB PHARMACY,

DR. JAI SINGH & SONS, Retail & Wholesale Chemists & Druggists.

Head Office removed to new premises in Anarkali opposite Students' Own Agency and LALA NARPAT RAI and DAVI DASS.

Old business premises the same, Waghewalla, City.

Large Stock just arrived from England.

Dispensing and Order Supplying Department open all day and night.

Most varied assortment of superior spices and medical requisites and sundries in Stock.

DR. B. L. DHINGRA, M.D., M.R.C.S., L.R.C.P., is using the late Dr. JAI SINGH's Consulting Room in the City Dispensary, Waghewalla, for morning consultation (7 to 9 A.M.) He will with the view of helping the business of a departed colleague give the benefit of his advice and general supervision to both the branches.

BOHAN SINGH, Manager.

Hoping that you will kindly bring this rather serious affair to the notice of the Indian Medical Association, and publish this letter in full in the *Indian Medical Record* for general information.

Yours &c., A BRITISH GRADUATE.

LUCKNOW, 26th September, 1898.

(Whether Mr. Varis, nor Mr. Bhagwandin has his name on the British Medical Register, but Mr. Behari Lal Dhingra is registered M.R.C.S. Eng., and L.M.S.P. Lond. 1894, we hereby call upon these gentlemen to immediately stop these advertisements, or this conduct on their part will be brought in the notice of the General Medical Council of Great Britain.—ED., I. M. R.)

—:—

MEDICAL WARRANT OFFICERS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I am amused to find in the last issue of your esteemed journal, a correspondent so "logically" protesting against my suggestion, or as he is pleased to call "contention" for placing the designations of Medical Warrant Officers on a par with other departmental officers of similar rank. My suggestion has had the approval of several of my colleagues with whom I have had the opportunity of discussing the subject, and therefore your correspondent may now disillusionize himself as to my—"voice being representative of any material section of us" Common sense should tell him that the suggestion is neither an "absurd" nor "pitiable delusion." On the other hand his argument against it and his nonsensical allusions to boatwains, carpenters, head cooks, cabbies &c., are quite beside the question; they make me smile! Why, according to his standard of thinking, the designations of officers of any department of the State may be made "suggestive" of anything absurd by a depraved flight of imagination. Take for instance the military rank of Captain, is it not also suggestive of miners, mariners, acrobats &c.? The Civil Service designation of Collector, may it not be made suggestive of bill-collectors, ticket-collectors, peons &c.? And those of Inspector, Commissioner,—of latrines, filth-carts, sweepers &c.; and so on *ad lib*? I am sorry also to find his equanimity being perturbed by vain imaginings of such bores as of "enemies laughing in their sleeves and chuckling over the belief that they have only to give us rope enough to see us hang ourselves." Now this, Sir, is real pitiable delusion! I say emphatically that I do not believe that we have any enemies at all, nor do I see reason why any body in the world should care to pose as our enemies. We all know of course that we once "struggled," and rightly struggled

too to be rid of the designation of Apothecary, and even at that early period my idea was that if a change were made it should be in keeping with the military designation of the sister services; but at that time there was not the slightest hope of its realisation. Now however the time has come, and under the circumstance what could be more appropriate, far reaching, and sensible than the designations suggested, which have had the "military ring" in them from time immemorial?

It is news to me to be informed by your correspondent that the designation Assistant Surgeon has a—"splendid history attaching to its past;" and also that it implies something "honourable." If so why does not the Government acknowledge it?

In conclusion, Sir, allow me to assure you that if you are not "flooded by indignant protests" against my common sense proposals, it will not be from any "unfortunate and chronic apathy" on the part of members of my department.

Yours &c., P.

(We heartily disapprove of our esteemed correspondent's ideas on this subject. We published his letters simply to allow an expression to all shades of opinion. Medical men cannot be dubbed "condemners." The new I. M. R. Warrant shatters P's notions.—ED., I. M. R.)

—:—

DISTRIBUTION OF MILITARY ASSISTANT SURGEONS TO APPOINTMENTS OF A STAFF NATURE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you kindly give the following grievance a place in an early issue of your highly esteemed paper, in order that it may meet the eyes of those who are responsible for selecting members of the I.S.M.D. to appointments of a staff nature, with a hope that these may be given to whom they are due, and not, as at present, to the juniors in a district, thereby causing an ill feeling in the service.

Looking at paragraph 55 of the Army Regulations, India, Volume VI, Medical, it is distinctly laid down that these appointments are to be made according to seniority; and if we as subordinates have to go by regulations, why not our superior officers? It is rather hard for a man who has toiled for years in the service, getting a comparatively small salary of Rupees 110, with a family to support, to be deprived of a just claim, and a junior of three years standing to have priority, whose salary is increased from Rupees 60 or 85 to Rupees 115, and more.

It has fallen to my lot to be debarred from getting such appointments when a junior, and again to be similarly treated as a senior, is, I can assure you, hard lines.

Yours &c., FAIR PLAY.

—:—

UNQUALIFIED RAILWAY MEDICAL OFFICIALS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I beg to bring to the notice of the Association in the interest of the medical profession in general, that we have in India many non-professional men holding appointments through influence only.

This matter I think ought to be taken up by the Council for the benefit of deserving men. These quacks must be put down.

I am informed that Dr. ——— Medical Officer of the R. M. Ry. is one of them. He does not hold a diploma and his medical knowledge is very poor. I am told he is a dentist. It is also stated that his evidence in a court of justice in a recent murder case was not taken, he not being a legally qualified medical man.

I therefore suggest that the Agent of the B. B. and C. I. Ry., and R. M. Ry. be addressed to call upon Dr. ——— to produce his medical qualifications.

Yours &c., A RAILWAY MEDICAL MAN.

(You are absolutely misinformed with regard to the medical man in question. He is L.R.C.P. and S. Edinburgh (1879) and is duly registered. ED. I. M. R.)

—————:O:—————

THE CIVIL ASSISTANT SURGEONS OF BOMBAY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Paras 7 and 8 of the recent Government of India Resolution anent the Civil Assistant Surgeons, require a few comments as far as they apply to Assistant Surgeons in the Bombay Presidency. Para 7 sanctions 4 appointments for Assistant Surgeons in the first class of the new scale on Rs. 350 (Rs. 300 pay with Rs. 50 allowances) mars the concession by insisting upon a limit of 21 years' service. This limitation tends to restrict unduly the selection of officers to the senior grade and this, in fact, is the ground on which the Government of India have decided not to insist on a limitation of 7 years' service to be passed in the Rs. 200 grade before further promotions in the case of Assistant Surgeons of Bengal and other Provinces. If, therefore, it is really desired to benefit the Assistant Surgeon of the Bombay Presidency, four of them now in the first grade of the new scale should be promoted at once to the newly created senior grade.

Para 8 lays down the number of Civil Surgeoncies allowed to each province. The allotment for Bombay is not only too small but also out of proportion with the rest of the provinces, notably Madras and the Punjab, the former of which is allowed five and the latter three, whereas Bombay is allowed only two. It is to be hoped that this number will be increased at once to at least four. It is not stated anywhere in the G. R. what period of service will be necessary for promotion to a Civil Surgeoncy. In the case of Bombay these appointments ought to be given to the first-grade men of the new scale. Those of the old scale have, comparatively speaking, been better paid and their pension prospects have now been improved, so they should be content with drawing their Rs. 350 p. m. to the end of their service. A comparison of the new and the old scale of pay will make this point clear.

	Old Scale.		New Scale.	
	Pay and Allowances.		Pay and Allowances.	
	Rs.	Rs.	Rs.	Rs.
1st Class	200	150	200	50
2nd "	150	150	150	35
3rd "	100	100	100	20

Promotion to these grades is by septennial periods.

Yours &c., BOMBAY A. S.

LIME JUICE AND GLYCERINE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you kindly let me know how many ounces I should reckon upon for *one pint* in the following prescription, and also how many ounces I should take for *one pound* in the same formula. I refer to the items of "Castor oil" and "Almond oil" respectively.

Cera Alba	3 oss.
Castor oil	1 pint.
Almond oil	2½ lbs.
Acid citric	2 oss. 2 dra.
Aqua	24 oss.
Glycerine	8 oss.
Ol. Limonis...	...	4 oss. 2 dra.
Spt. Vin roet	5 oss. & 6 dra.
Ol. Bergamot	½ oss. & ½ dra.
Ol. Geranium	½ dra.

Mft. all the three ingredients.

How would the above prescription be dispensed? I was given this formula by a friend who said that the above is a nice preparation for the hair, and is called "Lime Juice & Glycerine." The preparation he told me was excellent and very refreshing when applied to the head. It has a very creamy appearance.

Thanking you for a reply through the medium of your paper.

Yours &c., R. SMITH.

(Pint would mean 20 oz and lb 16 oz.—ED. I. M. R.)

—————:O:—————

HIGHLY PLACED ANGLO-INDIANS IN THE BOMBAY PRESIDENCY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—These few names will add to the increasing list of "Highly-placed Anglo-Indians" appearing in your Journal. Some of these names have been taken from the *Anglo-Indian Journal* of Bombay.

Edward Vander Straaten, Judge, Court of Small Causes, Karachi.

H. F. Carvalho, City Magistrate, Poona.

Charles Southey Marston, Deputy Collector, Sind Commission.

Benjamin Bradford, Deputy Collector, Hyderabad, Sind.

Archibald Henry Mullen, Surgn. Captain, I.M.S., Bombay.

Dr. Ed. Freeman Underwood, M.A., M.D., Ph.D., etc.

Dr. O. H. Freeman Underwood, L.R.C.P. & S. Edin.

Dr. H. L. C. Siets, M.D.

Dr. J. R. Marrett, M.B., C.M.

Dr. George Sinclair, M.B., Durbar Surgeon, Kolhapur.

Dr. Charles Spooner, M.R.C.S.

Dr. Alan Hawkins, M.R.C.S., etc.

Rev. Charles Gilder.

Mr. Fred Rowland, Merchant.

Rev. R. Spooner, A.P.O.

Mr. H. R. Wilcox, Civil Engineer and Surveyor.

Mr. Fred. S. Llewellyn, T. S. Nizam's State Railway.

Rev. G. K. Gilder, Presiding Elder, M.E. Church, Raipur.

Mr. Rowland Maidment, Assistant Collector of Customs.

Mr. W. A. Blunt, Dy. Supdt., H. M's Customs.

Capt. J. F. Raffin, Master Mariner, Merchant Service.

Capt. Geo. Baldwin, Master Mariner, Merchant Service.

Mr. Alexr. R. Lester, Chief Assistant Presy. Magist. Court.

Thomas Moss, Examiner, P. W. Accts.
 J. W. Fordham, do.
 Samuel Brock, do.
 Sherlock Hubbard, do.
 Walter Newman, do.
 S. J. Wood, do.
 G. W. Billings, do.
 Andrew Cowley, do.
 A. Condit, do.
 Alfred Grant, do.
 D. Gantz, Dy. Examiner, P. W. A.
 J. E. Lacey, do.
 J. E. Crisp, do.
 F. A. Moore, do.
 E. Swetenham, do.
 E. French, do.
 E. Anthony, do.
 C. W. Priestly, Assist. Secy., P. W. D., N. W. P.
 W. B. Butterfield, do.
 C. H. Sampson, do.
 J. E. Cooke, Auditor General, Financial Department.
 Simpson Byrns do. do.
 —R. Anthony, Dy. Acctt.-General, Financial Dept.
 D. G. Burbridge Asst. do. do.
 J. G. Firth, Deputy Collector, Madras Presidency.
 E. Firth, Chief Auditor, B. B. and C. I. Railway.
 A. Firth, Examiner of P. O. Rajputana.
 H. D. Theobald, Ditto.

Yours &c., W. H. T.

KARACHI, 17th September, 1898.

IMPROVING (?) THE PROSPECTS OF CIVIL ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The new rules published in the *India Gazette* improving the prospects of the Assistant Surgeons do not at all improve the prospects of the Assistant Surgeons in the Bombay Presidency, if anything they spoil the prospects of the future Assistant Surgeons in Bombay.

As it is, an Assistant Surgeon in charge of a Dispensary in Bombay draws Rs. 120, 185, and 250 according as he is of the 3rd, 2nd, or 1st grade. There was never any unemployed pay of Rs. 50 as seems to be the case elsewhere.

According to the new rules he will draw Rs. 100, 150 and 200 only, thus losing all the allowances that he gets. Moreover before he begins to draw Rs. 200 as 1st grade pay, he will have to satisfy the whims of the Inspector General of Hospitals who will allow a 2nd grade Assistant Surgeon to appear for his 1st. grade examination, only if he thinks proper. This means that there will be more 2nd grade Assistant Surgeons rotting on Rs. 150 perhaps for their whole term of service, than at present exist. This clause is apparently meant to make a saving to Government, for the paltry increase they have granted in the shape of Rs. 300 to Senior Assistant Surgeons who will only be promoted by selection, which means that men with back door influence will be given the highest pay of Rs. 300, and as only ten per cent. will be given the senior grade, it means that only four or five at

the utmost will be fortunate enough to get increased pay.

The whole Bombay service has lost all the allowances apparently for the sake of 4 or 5 influential men getting Rs. 50 increase to their pay.

You will thus see, Sir, that the Bombay Presidency has lost in place of gaining any benefits after all the agitation carried on for such a long time.

It can only be hoped that our good and kind Surgeon General, Dr. Bainbridge, will properly represent our case to the powers shortly and secure to us privileges and promotion befitting our education and industry.

Yours &c., MEDIOUS.

(If this statement of matters be correct, Bombay Assistant Surgeons have serious grounds for not blessing the new prospects.—ED., I. M. R.)

—:—

THE CALCUTTA GENERAL HOSPITAL.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I am only a woman and have no knowledge of medicine nor do I know the difference between doctors and doctors, nor have I much experience of hospitals, but I have read a good deal lately in the papers against the Calcutta General Hospital, against its management, its arrangements, its dietary, its nurses and also against its doctors. Now I do not think I can honestly praise the dieting or the nursing for both are bad, but I do wish to say a word for the doctor under whose care my husband was, during a few weeks of very painful and serious illness. I refer to DR. PILGRIM. No one could have been kinder or more considerate in all that concerned my husband's treatment and care while he was in the Calcutta General Hospital. It has been said that the doctors of this hospital are not willing to consult with private doctors over cases in the hospital. Well I wish to deny this, for when an operation was suggested by DR. PILGRIM, in my husband's case, I asked whether I could have the opinion of two private physicians and I named them to DR. PILGRIM. He at once said that I could call in any doctor I pleased in consultation. However as it seemed settled that my husband must undergo the operation, and we were both most timid and alarmed about it, I removed him from hospital for outside treatment, and DR. PILGRIM very kindly gave me a statement of my husband's case for the doctor to whose care I was transferring him.

I cannot sufficiently thank DR. PILGRIM for his goodness to my husband, and I only hope should I ever have occasion to enter the General Hospital that I shall be fortunate enough to come under his kindly medical care.

Yours &c., A. M. B.

CALCUTTA, 20th September, 1898.

(We are most happy to publish this lady's letter and we trust the fullest publicity will be given to the grateful recognition she desires to offer to the physician who had charge of her husband's case in the Presidency General Hospital. We happen to be personally acquainted with the facts of this case, and gladly substantiate what has been written above. The patient referred to died the very day he left the hospital.—ED., I. M. R.)

INSANITARY HOVELS IN CALCUTTA BASTIS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you kindly publish in your esteemed journal the following correspondence from the *Englishman*, to whom it was sent by Mr. W. C. Madge :—

"No city is safe unless its individual residences are healthy, and among these it is the humblest dwellings that claim attention first, not only in the interest of their own occupants but also in those of the wealthier inhabitants. Official municipal sanitation in Calcutta has hitherto reversed the course of all true reform, which is from the particular to the general. It has projected great and good plans wholesale on the city, trusting to Providence to make them reach the individual home. The result is a water-supply which is almost perfect, a drainage of much mixed virtue, and an improved death-rate tempered with strings of plague spots enough to cover the whole city with pestilence under quite possible conditions.

People are now paying from Rs. 3 to Rs. 5 a month for accommodation that is absolutely insanitary, and ought to be condemned as uninhabitable, while from 10 to 20 human beings are paying from Rs. 1-8 to Rs. 1 a month for their share, varying from one-tenth to one-twentieth, of compartments which ought to be denounced as unfit for human habitation, but in which the occupants lie down at night on damp floors side by side like sardines in a box. Even where, as in some others, the packing is less close, the superficial area and cubic feet of air allowed for each are so much less than those insisted on for convicts in jails that the wonder is that the victims escape, if they do escape, destructive disease. It is surely the simple duty of somebody to find out what is the best rent rate payable by the labouring and menial classes out of their wages, and to prove whether Calcutta is or is not a city in which a poor man can exist without falling a victim to preventable disease. The labouring population is fluctuating, to a larger extent, perhaps, than is generally suspected, because of constant decimation by disease, beginning here but ending elsewhere, and so avoiding the statistical net; but its tides as well as its other phenomena need not baffle study, if serious and earnest students can be found. Any sustained efforts, carefully placed outside our familiar spasmodic movements dignified with big names and ending in small facts, would in a very few years show whether the margin of profit from the rent of the worse type of tenements will admit of some portion of it being diverted to the improvement of the tenements. I believe that there is such a margin. If there is not, Calcutta is a doomed city, a final flight from which becomes merely a question of time. But with this margin established, legal compulsion would be justified.

Some might think it better for private enterprise than for the Corporation to enlist in this work. If the private native wealth of Calcutta—for its European wealth is fleeting—were lighted up with the far-seeing philanthropy which has reclaimed so many of the foulest dens of London, to the advantage of both landlord and tenant, it might not be necessary for the Legislature to move in the matter. But the economic conditions of Calcutta vary radically from those of any English city while the

demonstrable profit from investment of the kind referred to, though ample enough to justify public expenditure on public grounds, may yet not be attractive enough for speculators. Municipal authority may also in a city like Calcutta be needed to set up and keep going certain reforms in the state of solution in which most municipal interests now are, and will for some time continue to be. Will the enlightened English sanitary conscience, of which so much boast has of late (I do not say unjustly) been made in the face of Asiatic ignorance and prejudice, allow the municipal Law of Calcutta to be once more amended without making any effort to introduce provisions under which the Corporation (1) may, if necessary, prove by experiment what is the cheapest style of dwelling in which it is possible for human beings to live safely in Calcutta, and (2) shall, under severe penalties, prohibit the erection of any worse style of tenement in any part of the city?

This is surely an eminently practical question."

Yours &c., A. LAYMAN.

—:—

WHO ARE THE WARRANT OFFICERS OF THE INDIAN ARMY MEDICAL CORPS?

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Having read in your issue of the 16th August 1898, the above extraordinary heading, my curiosity was greatly excited and I perused the whole article carefully, with much disgust. (1) The designation—Indian Sub-ordinate Medical Department is a good one; probably the only bitter almond being the word *subordinate*. I am of opinion that it is well to leave this alone, only suggesting to those who cannot bear the sting of being styled subordinates, to try and get into the higher grades, or to find for themselves more congenial appointments.

(2) The proposal of our worthy friend P. to introduce Deputy Commissioners, Conductors and Sub-Conductors into a purely medical branch of the service is uncalled for. The public would soon run away with the idea that we were Conductors or Sub-Conductors, &c. of the Bombay Tramway Company, and not the Assistant Surgeons of old.

(3) I would kindly suggest to members to write about our two main grievances, i.e. enhanced rates of pay and suitable quarters. These two demands are of paramount importance and require the most urgent attention of the Director-General and the Government of India. Now, that the Civil Assistant Surgeons' question has been settled, I hope Government will see their way to relieving the existing state of bankruptcy now felt by the Military Assistant Surgeons.

(4) I have yet one small grievance to bring to the notice of the Director-General. It is a well established fact that the members of the Military Assistant Surgeon class in Bombay have a very few civil appointments: about twenty in all, and these are not plums. Yet I see that one of these appointments has lately been filled up by a Military Assistant Surgeon from Bengal, if this is only to be as a temporary measure, owing to the incidence of famine, plague, and frontier troubles, it calls

for no alarm, but should this practice become prevalent, the Military Assistant Surgeons on the Bombay side must eventually fare very badly. I for one cannot believe that this practice will be brought into force by our present benevolent Director-General, who I am sure will consider the question favorably and go into the existing state of affairs on this the Western side of India, and in due course open out more suitable appointments for a hard worked branch of the service.

Yours &c., A MILITARY ASSISTANT SURGEON.

BYOULLA, 24th September 1898.

—:O:—

LONG SUFFERING HOSPITAL ASSISTANTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Let me congratulate you and the Indian Medical Association for your persistent efforts to improve the condition of the local medical service and the partial successes which have crowned your efforts as far as the upper two classes (Apothecary and Assistant Surgeons) are concerned. It now remains for you and the Association to see that the miserable condition of the poor Hospital Assistants is improved and their grievances, regarding pay, prospects, status, and last, but not least, change of designation, considered. In the Educational, Engineering, Police and Telegraph Department, they have Inspectors, sub-Inspectors, Assistant sub-Inspectors; Overseer, sub-overseer, no designation will be more suitable and appropriate than sub-Assistant Surgeon for this class of subordinates. The term Hospital Assistant now in vogue is a misnomer, a ward boy and a compounder or dresser are all hospital assistants in the true sense of the word. I hope and request that the Indian Medical Association, will be pleased to approach the Government of India with a reminder for the immediate, just and generous redress of our grievances and that His Excellency, the present Viceroy will do something before he leaves India.

Thanking you and the Association very much in anticipation.

Yours &c., R. D. SINHA.

—:O:—

WHO IS IN CHARGE?

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Perhaps it may not be out of place mid all the changes in progress, to broach the subject of "Medical charges."

In the latter phases of the struggles of the R. A. M. Corps, it must have been the experience of many of our Assistant Surgeons in subordinate medical charges as it has been mine, to be corrected for writing "in medical charge" under the designation of officers in that capacity, according to regulations, the very pertinent question being put, "If I am only in medical charge who else here is in any other charge?" The only acceptable style is to write the Medical Officer in charge at the headings of official correspondence and at the foot under this rank and signature "In charge Station Hospital."

Now in cases where Assistant Surgeons are in charge of rest camps and such other detached outposts, the regulations very expressly lay down and reiterate that they are not in medical charge, but in "sub-medical charge" or "attached to" as the case may be. The question naturally arises who is in "medical charge"? and since the qualifying adjective is objectionable, as derogatory to those it is supposed to apply to, this insistence upon seeing that the omnivorous subordinate is not allowed to monopolise it, seems a very dog-in-the-manger business.

Yours &c., "PUZZLED."

—:O:—

FROM BAD TO WORSE. WHAT NEXT?

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—Your issues of the 16th August and 1st September, were received by me almost together, the former having gone astray for a while. The suggestion advanced by "P" in it, for changes in the ranks of the I. S. M. D. from Assistant Surgeon to Deputy Commissary, Conductor &c., are so utterly ridiculous as to be unworthy of comment. "An old Assistant Surgeon" in the subsequent issue (1st September) laments our unfortunate apathy in not flooding you with protests against "P's" proposal. It is not apathy, dear Mr. Editor, that keeps you from being flooded with protests, but the knowledge that such perverse ebullitions are not likely to be seriously considered and are best treated with ridicule or silent contempt.

Yours &c. ANOTHER ASSISTANT SURGEON.

Book Reviews.

SHEWSBURY: A ROMANCE.

By STANLEY J. WEYMAN.

Author of "*A Gentleman of France*"; "*Under the Red Robe*"; "*The House of the Wolf*," &c.

(Longman's Colonial Library)

MR. Weyman is a writer who can never fail to enchain and delight his readers, and his latest work, it may safely be affirmed, is no exception to the rule. We refrain, from obvious reasons, from retelling the story, which, it may be, observed, is one of the days of the English Revolution and the Rebellion afloat about that time. The illustrations—twenty-four in number—are from the pen of that rising young artist, Mr. Claud A. Shepperson.

COMFORT AND CLEANLINESS? THE SERVANT AND MISTRESS QUESTION.

By MRS. CATHERINE, M. BUCKTON,

Author of *Health in the House*, &c.

(Publishers: LONGMANS GREEN & Co., pages 96; Woodcuts; price 2s.)

THIS practical little brochure is certain to prove exceedingly useful to house-keepers at home. Chapters are

devoted to the ventilation, lighting, and sanitation of the house, kitchen, and area, while, some very important hints are given on cleaning out, &c.

SCIENTIFIC METHOD IN BIOLOGY.

By ELIZABETH BLACKWELL, M.D.

(Publisher : ELLIOT STOCK, London, pages 80.)

How far the guidance of conscience can extend, in relation of the methods employed in investigating biological phenomena, with the practical results to medical research involved in the recognition of such guidance, form the subject of the booklet before us. The chapter on restriction of experiment, is more or less a plea against vivisection and other experimentalising on the lower animals. Such being the case the views of the authoress are set forth gracefully and sympathetically.

ESSENTIALS OF EXPERIMENTAL PHYSIOLOGY.

By T. G. BRIDIE, M.D.

Lecturer on Physiology, St. Thomas' Hospital Medical School.

Publishers : LONGMANS GREEN and Co.,

(Pages 229 ; Price 6s. 6d.)

THIS work contains, for the benefit of the student community, a succinct account of such operations as may be carried out by students in their class rooms, as well as a selection of experiments suitable for demonstration in class. It is profusely illustrated, and the cuts, it may be observed, are original ones.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Lieut.-Col. James Joseph Moran, M.D., I. M. S. (Madras), has been permitted to retire from the service, from 10th Oct. 1898.

Hony. Capt. George Henry Cambell, I. S. M. D. (Bengal), is permitted to retire from the service.

Hony. Surgn.-Capt. William Marcus Mitchell, I. S. M. D., (Bengal), is permitted to retire from the service.

Brig.-Surgn.-Lieut.-Col. C. W. Carr-Calthrop, M.D., I. M. S. Bengal Estb. is granted the tempy. rank of Surgn.-Col. from 18th Aug. 1898.

The services of Surgn.-Major W. B. Bannerman, M.D., I. M. S. (Madras), are replaced at the disposal of the Govt. of Madras.

"The undermentioned probationers for the I. M. S. have been apptd. Surgn.-Lieuts. from the 27th July 1898 :—

Thomas Hunter, (Bengal); Walter Bothney Battye, (Punjab); Harold Budgett Meakin, (Bengal); George Hutcheson, (Punjab); William Glen Liston, (Madras); Harold Boulton, (Punjab); Richard William Anthoney, (Bombay); Earnest Frederick Gordon Tucker, (Bombay); George Edward Stewart, (Bombay); Frank Stuart Corbitt Thompson, (Bombay); Thomas Shephard Norris, (Bombay); John William Watson, (Bombay); Herbert Joseph Richard Twigg, (Bombay); Charles William McGillicuddy Orpen (Bombay).

Ast. Surgn. John Goldsmith to be first-class Ast. Surgn. from 16th July 1898.

Ast. Surgn. and Hony. Surgn. Alfred Birthright Bates, to be Senior Ast. Surgn. with Hony. rank of Surgn. Capt.

Ast. Surgn. Henry D'Lacy to be Senior Ast. Surgn. with hony. rank of Surgn.-Lieut.

Ast. Surgn. Samuel George Dingavan to be first-class Ast. Surgn. Ast. Surgn. John Vincent James to be second-class Ast. Surgn. from 22nd July 1898.

BENGAL GOVERNMENT.

The services of Dr. W. A. Justice, M. B., C. M., are temply. placed at the disposal of the Insp. Genl. of Civil Hosp., Bengal.

Ast. Surgn. Bas Behari Mottra, to Tikari dispy. Gaya dist. Ast. Surgn. Narendra Nath Basu, House Surgn. Ist. Surgeon's Ward, Medl. Coll. Hosp. to be, House Surgn., Eden Hosp.

Ast. Surgn. Nobin Chunder Dutt, Darbhanga Raj Hosp., leave for three months.

Ast. Surgn. Surat Lal Basu, to Darbhanga R. J. Hosp. Brig.-Surgn.-Col. F. A. (retired) to act as Civil Surgn. of Darbhanga

Surgn.-Capt. B. H. Deare to be Deputy Secy. Commr.

PUNJAB GOVERNMENT.

The services of Ast. Surgn. Lala Abnashi Ram, Karnal Dispy., are placed at the disposal of the Govt. of India, Foreign Dept., from 11th Aug. 1898.

Capt. D. M. Davidson, M. B., who was placed on special duty by Punjab Govt., was employed on plague duty. Jullundur Dist., from 26th Nov. 1897.

Surgn.-Capt. A. W. T. Bulst, Offg. Civil Surgn., privilege leave for 50 days, from 2nd July 1898.

Surgn.-Capt. Brist assumed charge of Offg. Civil Surgn., Delhi. and Supdt. Lunatic Asylum, 20th Aug. 1898.

Surgn.-Major S. Little assumed charge Civil Med. duties, Rawalpindi Dist. 30th Aug. 1898.

Surgn.-Major G. W. P. Denny resumed charge of his duties as Civil Surgn. Sialkot. 8th Sept. 1898.

CENTRAL PROVINCES GOVERNMENT.

Ast. Surgn. and Hony. Surgn. Capt. W. M. Mitchell, M. D., Bengal Estab. to be granted the hony. rank of Surgn.-Major, 17th Aug. 1898.

Hosp. Ast. Surgn. Dranath Chakravarti, doing duty under Civil Surgn., Saugor, to Police Hosp. Saugor.

Hosp. Ast. Ramkrishna Balwant, Betul Branch Dispy. Betul Dist., three months' privilege leave.

Hosp. Ast. C. K. Ranganadam, doing duty under Civil Surgn., Nagpur, to Betul Branch Dispy.

Hosp. Ast. Pandurang Lakshman, Jail and Police Hospls. Ohhindwara, two months' privilege leave from 6th instant.

Hosp. Ast. Bhagwan Das, Main Dispy., Ohhindwara, to hold charge, Jail and Police Hospls.

Hosp. Ast. Vithal Anand Rao, doing duty under Civil Surgn., Nimar, to Mandhatta Branch Dispy., Nimar Dist.

Hosp. Ast. Abdul Karim, Mandhatta Dispy., to Arung Dispy., Raipur Dist.

Hosp. Ast. Shaikh Wali Muhammad, Arung Dispy. to Jail and Police Hosp., Betul.

Hosp. Ast. Nand Kishore to Jail and Police Hosp. Ohhindwara.

Hosp. Ast. Narayan Vinayak, doing duty under Civil Surgn. of Bilaspur, to Janjgir Branch Dispy., Bilaspur Dist.

Hosp. Ast. Kaluram, to do duty under Civil Surgn. of Raipur.

N.-W. P. AND OUDH GOVERNMENT.

Amt. Surgn. M. H. Thomas, Off Lecturer on Materia Medica, Med. School, and in charge of Thomason Hosp., Agra, to Sadar Dipty, Dehra Dun.

Amt. Surgn. Sri Ram, to reserve duty at Gorakhpur.

Amt. Surgn. Sri Ram from Reserve duty at Gorakhpur to that at Lucknow.

G. O. C. C.

Surgn.-Capt. E. B. Parry, M. B., to the medical charge of the 96th Bengal Infantry.

Amt. Surgn. A. A. W. White, leave for four months, on medical certificate.

BURMA GOVERNMENT.

Amt. Surgn. Bhagwan Das made over, and Amt. Surgn. F. Bradley assumed, charge Civil Surgnry. of the Upper Chinthein dist., 5th Sept. 1898.

Amt. Surgn. E. G. O. Prins, assumed charge Genl. Hosp., Rangoon, 26th Aug. 1898.

Hosp. Amt. T. L. Thomas, three months' privilege leave, 15th July 1898.

Hosp. Amt. Maula Buksh, assumed charge, Mil. Police Hosp. Myitkyina, 2nd Sept. 1898.

Hosp. Amt. Hema Chandra Koyal, assumed charge, Civil Hosp., Maungdaw, Akyab dist., 27th Aug. 1898.

Hosp. Amt. Radhnath Singh, two months' privilege leave, 8th Sept. 1898.

Hosp. Amt. M. Henry Peter assumed charge, Civil Hosp., Mogaung, 8th Sept. 1898.

Hosp. Amt. F. A. Francis, assumed charge, Mil. Police Hosp., Mogok, Ruby Mines dist., 8th Aug. 1898.

Hosp. Amt. Gajan Singh, assumed charge, Mil. Police Hosp., Kindat, Upper Chinthein dist., 25th Aug. 1898.

Hosp. Amt. Gajan Singh, assumed charge, Outpost Hosp., Kalewa, 31st Aug. 1898.

Hosp. Amt. M. Thungavelu Mudeliar, to Mogaung, Mandalay, 4th Sept. 1898.

Hosp. Amt. M. Thungavelu Mudeliar made over, and Hosp. Amt. Maung Tun U, assumed charge of additional duties, Look-up, Mandalay, 8th Sept. 1898.

Hosp. Amt. Jeet Singh, relinquished charge, Mil. Police Hosp., Myitkyina, 7th Sept. 1898.

Hosp. Amt. N. Sabbiah Pillay, leave for three months and 28 days from 25th April 1898.

Hosp. Amt. N. Sabbiah Pillay, assumed charge, Jail Hosp., Rangoon, 17th Aug. 1898.

C. Gosh is appointed on probation as a Third Grade Hosp. Amt. and posted to Civil Hosp., Akyab, for duty.

ASSAM GOVERNMENT.

Sick leave for sixteen days, is granted to Hosp. Amt. Kotiavar Guha, in extension of the one month's sick leave granted 27th July 1898.

Hosp. Amt. Bisan Charan Banerji, Manipur Dipty. to Sylhet dist. Bhanga Dipty. in that dist. from 17th Aug. 1898.

Hosp. Amt. Nabin Chandra Datta, Banjachong Dipty., Sylhet dist., to Lusal Hills dist. apptd. tempy. to Tenzol outpost in that dist., from 19th Aug. 1898.

Privilege leave for two months, is granted to Hosp. Amt. Chandra Kisor De, Nowgong Jail and Police Hosps from 3rd. Sept. 1898.

Hosp. Amt. Kotiavar Guha, to Nowgong Jail and Police Hosps. from 3rd Sept. 1898.

Privilege leave for one month is granted to Hosp. Amt. Durga Charan Sen Gupta, a Supery. at Gauhati, from 6th Sept. 1898.

NOTICES TO CORRESPONDENTS.

J. R. (Koharu).—We see no reason why Civil Hospital Assistants should not be promoted to Assistant Surgeons if they undergo the necessary qualification. You should apply to Government to allow you this privilege.

V. P. A. P. (Kamptee).—Our Manager is responsible for your addressed cover. He wishes to please everybody and we trust he has given you satisfaction.

G. N. (Agra).—No letter received, post card to hand.

T. W.—Your notes regarding the Eden Hospital have been received. We shall comment on the management of this institution later on.

G. H. K. (Calcutta).—Complains of the nursing arrangements of the Calcutta General Hospital and states that the nurses are above their work. He says the native sweepers administer enemata and wash the patients who are bed-ridden. If this is true it is disgraceful.

D. A. writes :—"I beg you will kindly inform me whether the orders of Government debarring natives of India, Goanese, Jews, Parsees &c., from entering into the S. M. D. i.e. Military Assistant Surgeon class, has been rescinded or in any way relaxed of late. "Having a promising son, I am personally interested in the matter and therefore solicit this information, as only two years ago the son of Military Assistant Surgeon—(Bombay Circle) named———was admitted into the Grant Medical College, Bombay, as a Military Pupil and is now studying for that service." "I am personally acquainted with the family of this lad and can positively assert that he has no claim whatever from parental lineage to represent himself as an Eurasian, and I shall be extremely obliged by your kindly informing me the as to the circumstances under which this lad got entrance in the service.

"I can only account for it in one of two ways, viz:—

"(1).—A special consideration on account of the father being in the service. (2).—That the father or the lad apparently furnished a false certificate, necessary by regulation for admission.

"The rules of the service are very clear, and if they have been driven through under the garb of falsehood, an example ought to be made of the case in question."

W. C. (Calcutta), writes :—"An elderly lady, (45), who complained of suffering from prolonged hæmorrhage went to a well-known hospital of this city, was seen by one of the junior officers who doubted her word and said so to his class. She was admitted into the hospital, examined with a sound and it was said she was not pregnant. The next day the woman aborted. This is another case of "abortion by inadvertence."

ORIGINAL ARTICLES.

THE MEDICINE OF SUPERSTITION.*

By WILLIAM EDGAR DARNELL, A.B., M.D.

Atlantic City, N. J.

THE practice of medicine is as old as history itself, but the science of medicine is quite young. Perhaps the latter half of the present century will embrace the time since medicine has been studied in a true scientific spirit. God-given from APOLLO to his son ÆSCULAPIUS, according to the Greeks, the healing art was in its early days clothed in mystery; and to the ignorant it yet remains a semi-mysterious realm. Its history is wrapped in superstitious customs and associated with strange ceremonies, which have been handed down from generation to generation for many centuries. Medical therapy was often linked to witchcraft in the person of some old hag, toothless and wrinkled, who aped acquaintance with the supernatural and could dissipate disease with a charm. The busy practitioner finds yet almost daily examples of such "old granny" superstitions regarding disease existing in the gullible minds of the uncouth; and they will give up their doctor sometimes rather than weaken their faith in them. Indeed traces of these superstitions are often discovered among people who are quite intelligent in other respects. Very seriously did an old lady take me into her confidence one day by divulging a remedy for obstinate nose bleeding. Three strands of silk thread tied around the neck, said she, would stop it after all else in the way of medicine and doctors had failed, for she had seen it tried. Who has not heard of the horse chestnut or the lump of sulphur carried in the pocket for rheumatism; the bag of assaetida about the neck or a raw onion wrapped in silk to keep disease away; and the string of amber beads for croup?

Ancient writings tell of how the Persian, Magi, or wise men, knew of herbs which, wrought into pills and swallowed in wine, would make the guilty confess their secrets. There was an herb for begetting good and handsome children and a wort to revive old love, when it had turned to hate.

The palpitating heart of a mole, when swallowed, gave one the art of divination, while the heart of a hen, they said, placed upon a woman's left breast while she slept would make her tell her secrets.¹

Amulets played a prominent part in the remedies described by PLINY, many of which are curious. For malaria he prescribed the dust in which a hawk was rolled; the longest tooth of black dog; a solitary wasp caught in the left hand; the head of a viper cut off, or its living heart cut out and wrapped in a piece of cloth; or the snout and tips of the ears of a mouse.²

The Chinese still retain much of the folly of their ancient materia medica. It is said that much of the feeling engendered against the foreign missionary physicians in China is due to the firm belief the natives have in the efficacy of the eyes and vitals of the human body

in disease. They spread the rumor in more than one instance, that the foreign doctors, whose skill they were forced to admit, obtained their medicines by kidnapping and murdering Chinese children—a general massacre of the Christians following as a result of their jury.

MITFORD describes seeing a Chinese doctor give a child with fever a decoction of three scorpions. The European leech of the last century held in high esteem the ashes of a burnt witch, for gout or fever. Ague in Ireland was to be cured by the sufferer swallowing a living spider. In Somerset, England, a large black spider was shut in a box and left to perish; and in Flanders a spider is imprisoned in walnut shell and worn around the neck. In Lincolnshire a girl suffering from ague cuts a lock of her hair and binds it around an aspen tree, praying it to shake in her stead. The first violets of the season may be chewed or a three-colored cat kept in the house.

Even in sturdy New England the superstition of the mother country leads to the manufacture of pills of spiders' web as a cure for ague, and Longfellow refers to the traditionary remedy for malaria.

"By wearing a spider hung around one's neck
In a nutshell."

In Japan the ancient medicine man dealt largely in carbonized animals. The rarer the animal and the further it has travelled the more remarkable the cures accomplished by it. Tigers' claws, teeth and skin were valuable, and especially the center of the tiger's eyeball. The joyous lizards which dart about in the sunlight were popular as vermifuge. Toads' paws, wolves' eyes, vultures' claws, human skin and fat were thought to possess remarkable virtues. Although China has advanced but little in medical science Japan has, and, having broken the shackles of superstition, at the present day occupies a place in the front ranks of the profession which is much to her credit.

The Japanese remedies mentioned are not worse than the mummy dust so highly prized in Europe and recommended in the standard medical works of Nuremberg two hundred years ago. So much in demand was it that only the wealthy could afford it; and it is a fact well known to history that this formed the principal ingredient of the well-stocked medicine chest FRANÇOIS I. of France valued so highly and kept ever near him.

"The hare's gall mingled with honey brighteneth the eyes," says an old chronicle; and an ointment made from a wolf's eye was the best prescription of the ancient Saxon oculist. Ear from alluring is the practice in Aberdeenshire. The cure for sore eyes is to lick the eyes of a live frog. The person thus healed has thenceforth the power of curing all sore eyes by merely licking them. So in Ireland to the tongue which has licked a lizard all over is ascribed the marvelous power forever of healing whatsoever sore or pain it touches. As a preventive of sore eyes we are told by MARCELLUS that when a shooting star is seen, as many numbers as possible should be counted, for as many years as you count numbers you will avoid inflamed eyes. The Saxons use the juice of an emmet's egg or the gall of a goat for deafness. Extreme cases were cured by a mixture of equal parts of boar's gall, buck's gall, and honey, with sometimes the addition of very nasty ingredients. One prescription directs that

"the bowels of an earwig be powdered with the smede of whatever meal and the netherward part of marche and mingled with honey."

They also devoted much attention to their hair. Falling of the hair might be prevented by dead bees burnt to ashes and seethed in oil with willow leaves. If the hair were too thick "then must a swallow be burned to ashes under the tile and the ashes sprinkled on the head." For a depilatory emmet's eggs were rubbed on. Various forms of disease were combated by the heart of a fox mingled with frankincense, and the oil in which various portions of this animal's body had been seethed averted baldness, "then the hair holdeth on and the salve compels that it shall grow."

In a quaint volume printed in 1712 in Edinburgh, "A Collection of Useful Remedies for most Distempers," collected by JOHN MONCRIER, we find that the head washed with a lee of the ashes of cow's dung, then the burnt ashes of little frogs applied, cures the falling of the hair called alopecia. Other medicaments mentioned are: The burnt ashes of goats' dung mixed with oil; the ashes of a goat's hoof mixed with pitch; the blood of a shell crab. However, the blood of a bat, or a little frog, the powder of swans' bones or the milk of a bitch hinder the growth of the hair.

For toothache our ancestors had also some remarkable remedies, such as spitting into the mouth of a frog and telling him to be off with it. Also for pain of jawl a swallow burnt to dust and mingled with field bees' honey should be given the patient to eat frequently. The gall of a he-goat mingled with oil, or the tusks of a hound burnt to ashes and sprinkled on wine may be given the man to drink. "Hideous," says GORDON CUMMINGS, "is the remedy for toothache practiced at Tavistock in Devonshire. A tooth must be bitten from a skull in a church yard, and kept always in the pocket." We find also a preventive in trimming one's nails on Friday, and as a cure for toothache, the eating of bread a mouse has nibbled. Kiss a mule or rub the gums with the body of an ant, beetle or fly.⁶

For epileptic fits the cures were as numerous as they were horrid. The *Chinese Repository* published in 1832, relates that dragon's bones may be used. These may be found on banks of rivers and in caves of the earth, places where the dragon died. The best are known by slipping the tongue lightly over them, but if these are taken from damp places or by women they are worthless. Old English medical works of high authority recommend powdered elks' and deers' horns; and in Caithness only a few years ago the skull of a suicide was used as a drinking cup for the cure of fits. Dr. ARTHUR MITCHELL recounts a case in which the body of a suicide was disinterred in order to obtain the skull for this purpose. To reduce such a skull to powder and swallow part of it was a sure specific. Even the moss which grew on such skulls was deemed highly efficacious for certain ills. This is mentioned in the official *Pharmacopœia*, London, 1678. This same work in 1724 refers to unicorn's horn, human fat, human skulls, dog's dung, toads, vipers and worms as possessing real value in disease.

Scotland likewise followed the skull treatment for epilepsy. Sir JAMES SIMPSON knew of a case in Rosshire of a lad attacked with fits. Mole's blood was given but failed; and a messenger was sent nearly a hundred miles for a bit of the skull of a suicide, which was scraped to dust, mixed with water and administered to the boy. Sometimes the epileptic was made to drink blood drawn from his own arm. Here is another cure that reminds one of the old well-known remedy of rubbing a gold ring on a sty to abort it. It is to "draw the brain of a mountain goat through a golden ring, give it to the child to swallow before it tastes milk and it will be healed." As a sacrificial remedy living cocks were sometimes buried; while blood from a weasel, seven drops of blood from the tail of a cat, or blood from a recently executed criminal are all remedies for this strange malady—which we are still far from thoroughly understanding.

Insomnia was baffled by placing a goat's horn or wolf's head under the pillow. The wolf's flesh was also a cure for "devil sickness," and Miss BIRD has described how great faith the Chinese place in the dried blood of the tiger, which they so much admire, as a tonic, giving strength and courage to him who takes it.

During the sixteenth century the horn of the unicorn was deemed the best antidote to poisons; and in that treacherous age, says CUMMINGS, drinking cups were carved from it as a safeguard on account of its neutralizing powers. At the close of that century on one occasion the learned doctors of Augsburg met in solemn conclave to examine a certain specimen of unicorn's horn and decide whether it was the true monoceros or not, which they determined by an experiment on a poisoned dog.

SPIDER's bite was antidoted by the sinews of a fox swallowed raw; and the rennet in wine was given for the bite of a serpent. In Devonshire, England, a person bitten by a viper is advised to kill the creature and rub the wound with its fat. This same treatment has survived in some of the northern states of America and reminds one of the traditional "hair of the dog is good for the bite"—a true homeopathic *similia similibus curantur*.

The living fox seethed till the bones alone are left, makes a foxy essence which was reputed a sure cure for disease of the joints if rubbed thereon. The medicine of the long ago known as *Pulvis æthiopicus*, which was deemed so valuable as both an external and internal remedy was neither more nor less than powdered toad. In Devonshire the "wise man" for the relief of rheumatism will burn a toad to ashes and tie the dust in a bit of silk which the sufferer must wear around the neck. To the sick poor who are rarely lacking in the primary necessity of faith in the means adopted, frogs are well nigh as valuable as toads. Thus frog's spawn, placed in a stone jar and buried three months till it turns to water is regarded by the people of Donegal as a wonderful cure if rubbed into a rheumatic limb.

The snake also comes in for a share of consideration for palsy, leprosy and rheumatism, in the early medical lore of both Japan and Britain. Even in this country, according to Black's *Folk Medicine*, the New Englanders are accustomed to wear a snake skin around the neck for rheumatism. This is no doubt a direct heritage from the medical traditions of the mother country; but we are

⁶ *Journal of Practical Medicine*, February, 1898.

also told the Indians of America made use of rattlesnake oil for the same malady. Patients with rheumatic gout, however, found a potent remedy in the wearing of a copper ring made from a coffin nail. Also if the patient carry on his person the tooth of a mole or a dried toad.

The different things that have been and still are used by the ignorant as styptics would alone fill many pages. Here are a few of them. The goat's liver pounded with vinegar; the juice of swine's dung (perhaps for its aseptic (?) properties); snails; ashes of burnt frog or hens' feathers; cobwebs; the herbs, shepherd's scrip and knot grass, "which have the property of stanching blood by merely looking on them." Drop vinegar water on the face of the patient who shall lie on his back all naked. Dry a toad well in the sun, put it in a linen cloth and hang with a string about the part that bleedeth, or let it touch the breast of the left side near the heart.

A strange custom prevails in Sunderland, where the inhabitants, for the relief of whooping cough, shave the head, and hang the hair upon a tree or a bush, believing that, as the birds carry away the hair, so will the cough vanish. While the people of Ireland, who have abundant faith in charms, keep headache off by thrice going around a certain tree at the holy well of Tubbar Quan on their bare knees, then cutting a lock of hair which must be tied to a branch of the tree as a charm.

Almost as many cures for cancer obtained in former times as at present for the affliction, and were attended with about as much success in the end. Only two or three will be mentioned: the fresh warm flesh of a hen or a pigeon applied to the sore; the ashes of a mad dog burnt to dust, and especially human excrement.

For hard tumors and swellings, goat's flesh should be burnt to ashes and smudged on with water. Again, shavings of the horn of a hart are useful to disperse ill humors and gatherings, as are also wood ashes seethed in resin; goat's horn burnt and mingled with water or its dung dried and grated and mingled with lard.

Is it much wonder that the human mind struggling in such a slough of discord and without perhaps a single idea of physiology or the science of medicine should ascribe to the kings of the last century, who were admittedly divine in everything else, the divine power of healing "King's Evil" or scrofula simply by a touch? Even to-day the approved treatment of this trouble in some parts of England is as senseless as in the days of CHARLES I., the "great healer."

The hind leg of a toad is to be dried and worn in a silken bag around the neck, or else that part of the living reptile answering to the part affected by scrofula is cut off, wrapped in parchment and hung around the neck of the sufferer. In Essex it is the vile snake again which must be drawn nine times across the neck, then killed and its skin worn, sewed in a piece of silk. Sometimes the snake is put in a bottle tightly corked and buried in the ground. It is expected that as the victim decays the swelling will subside.

SAINT ANTHONY'S fire or erysipelas was to be cured by the burnt hairs of a hare or the delectable medication of a plaster of earthworms or bullocks' dung still warm. Better still, at least not quite so disgusting, burn a swallow's nest, dung and all, rub to dust, mingle

with vinegar and smear therewith; and also a goat's horn roasted and pounded with acid reduces the inflammation of erysipelas.

The means employed for the relief of goitre are even more harrowing than some that have been mentioned for other maladies. Oil from a lamp that has burned beside a death bed may be rubbed on the swelling; but in some parts of Britain the horrible charm of having the hand of a dead child rubbed nine times across the goitre must be undergone. It is even better if it is the hand of a suicide. Mr. GORDON CUMMINGS* relates a case which occurred not so many years ago in which a poor woman living near Hartlepool, acting on the advice of a "wise woman" went alone by night to an outhouse where lay the corpse of a suicide awaiting the coroner's inquest. She lay all night long with the cold hand of the corpse resting on her even; but the mental shock of such a night of horror was so great that she shortly after died before it could be determined whether the treatment would have been successful or not!

—:O:—

THE TEMPERANCE QUESTION AND BIOLOGY.

By WM. HUNTLY, M.A., M.D., B.Sc.,
Nussereabad.

In *The Medical Magazine* for June and July and later on in pamphlet form there appeared two articles on "The Temperance Question from a Biological stand-point." We had anticipations of great things when we began to read the pamphlet and incidentally invited the attention of a fellow doctor while we proceeded to read it aloud. Our anticipations had promised for us an account of experiments undertaken on the lower animals and even on the humbler organisms as far down in the scale as say the the schyzomycetes or the saccharomycetes, and we were wofully disappointed. Of experiments there were none. On the contrary it was an essay on the temperance question looked at from the evolutionist's point of view. But the essayist supplies his own theory of evolution and herein lies our difficulty to begin with. If we grant that two and two make five, we must be prepared to take the consequences, but if we calmly refuse to admit that two and two make five, the argument from that point fails.

Dr. REID has his own notion of Evolution and has studied the subject to the extent of writing a treatise on "The Present Evolution of Man," and we learn that he has in that volume laid down a theory of alcoholic evolution which he informs us, "has met with general assent from biologists."

In this essay he tells us,—"I have endeavoured from a biological standpoint merely to discover the origin of the craving for narcotics to account for racial differences with respect to it, and from that standpoint to demonstrate the futility of "temperance reform" as the phrase is commonly understood." In place of "temperance reform" he also has a little scheme of his own, which of course in his own mind is quite in harmony with his evolutionary ideas and is its logical consequence. We will state his wonderful substitute for "temperance reform" in his own words, for he professes a zeal to save the victims of intemperance. "It is in our power" he writes "to aid

most actively, but as yet the peculiar moral sense of this half-civilised community forbids. Nevertheless in the overcrowded world which looms in the immediate future, our descendants, if spared by "temperance reformers," will surely adopt it and breeding only from the best, solve thus, this and other kindred questions. It is in our power by copying nature, by substituting Artificial by Natural Selection, to obviate much of the misery incident with the latter, and thus rapidly to evolve a sober race. It is of course not part of the scheme here propounded to destroy drunken persons, nor even to permit their self-destruction by drink. *Having by means of alcohol discovered the innate drunkard, let us by all means, if it be practical, keep him sober; but let us safeguard the species by forbidding the procreation of children by him.* This would be no new thing in the world, for already in practice we prevent the marriage of imbeciles and lunatics. I think, however, that it would be impossible to prevent the marriage of the innately drunken, if only for the reason that frequently the craving is not manifested, especially among women, till later in life; but a system of fines and punishments would soon check the birth rate.....To achieve real success we must eliminate not drink but the excessive drinker, at least in so far as to prevent him influencing the race by having children."

It does not require us to think over the new scheme above propounded, before we feel that we are reading a counsel of despair. We can fancy another evolutionist taking up the question of thieves and theft, propounding a like theory and suggest that as all the laws ever framed have been unable to put a stop to the profession of the thief, we should revert to artificial selection or compel by certain fines, etc., the thief or shall we say the excessive thief (not moderate thief) from influencing the race.

And we look forward to a future in which each man who proposes to enter the bonds of marriage and be a probable father will have to present himself before a committee of selection. The prospect can easily be extended. Every imaginable disease under the sun has only to be treated in this fashion and in a brief epoch the world will be filled with moderately sober men only inclined moderately to theft and moderately towards the exercise of the passions and so on. What a world of vain Pharisaical pride we should have in due course. True help to a fellow man if he needs it, is help to suppress him for ever, and doubtless our evolutionary friends would set up the same method of cure for poverty. Poverty does neither sound well or look well to our "survival of the fittest" theorists, for of course our evolutionist always reckons himself physically and mentally to be a glorious example of the survival of the fittest. The writer of the essay (sic) concerning the speculations of other writers writes this airy sentence,— "That such speculations have any scientific value, or are other than a species of solemn and fatuous trifling, I am not prepared to admit." Certainly Sir, go on steadily in your own solemn and fatuous triflings and then present yourself before the selection committee to see if they will adjudge you worthy of influencing the race.

"A system of fines and punishments would soon check the birth rate." We simply decline to discuss such nonsense. Why the children are generally born before excessive drunkenness and the case for it, is established. In another portion of his essay he believes he has proved that the craving for alcohol is innate and cannot be transmitted and writes that, "an undying fame awaits the writer on inebriety, who shall prove that the acquired effects of alcoholism are transmissible;" and adds that, "if acquired characters are transmissible prohibition is undoubtedly right; if they are not transmissible no more foolish and suicidal policy was ever thought of."

All through his essay, the writer mixes up "acquired characters," "acquired effects," "parental drunkenness," and other similar terms, but whatever he is struggling to express, his treatment all implies that the parent does transmit something which affects the offspring in its relation to the drink craving.

It will surprise our readers to learn that he adduces in support of his theory what he terms facts elicited by the Royal Commission on Opium. He writes that "Witness after witness, men of high official or scientific standing, endowed with the best opportunities of arriving at a correct judgment, such men as Sir JOHN STRACHY, Sir JOHN BIRDWOOD and Sir JOSEPH FARRER declared that they had never in all their experiences seen a native of India the worse of opium. There was in fact a general consensus of opinion that of all races the natives of India are the least prone to excessive indulgence." Without going into details every reader, whether he belongs to the pro-opium or anti-opium party, will agree that he has not quoted the real opinion of the Commission and that if the above statement was really made by the three authorities mentioned above, the conclusion drawn therefrom is of equal value with the conclusion drawn from the witness who said he had never seen a tiger in India, that there are no tigers in the country. We might incidentally ask Dr. REID, the writer of the farrago of evolutionary nonsense, to ask the Brahmins and the leaders of other castes in India, why they believe in prohibition and enact it for their respective castes. He might also find out something about the native being "least prone to excessive indulgence," if he attended a good feast, and understood the phrase "pet-bhar khaya": he might also live for a week or two in the neighbourhood of a liquor shop (native), and he might infer something from the laws against drink in the Methodist Church in India and from the total-abstinence movement which has been espoused with enthusiasm by many leaders of the people of India. The modesty of the writer can be gathered from the following,— "May I be permitted in conclusion to quote my own words," when he has been all through busily engaged in quoting himself without apology.

The last words in his scheme of alcoholic evolution are these,— "It is surely clear that if the world is to become more temperate it must be by the elimination, not of drink, but of the excessive drinker. If artificial selection be found impracticable in the future, as, owing to the state of public opinion, it undoubtedly is at present, then the only alternative is Natural Selection, in which case the world will never be thoroughly sober until it has first been thoroughly drunk." In plain prose, the

remedy from our evolutionist friend is the policy of drift. We do not expect that any one with the welfare of their fellow-men on their consciences will accept either the one remedy or the other, and if this is the logical outcome of the application of the so-called evolutionary theories of the writer, we would doubt the truth of the premises and the theory from which he argues, and be inclined to vote the conclusion and theory as in the writer's own words "a species of solemn and fatuous trifling". All that his essay requires are a few daring sketches from the pen of the artist who adorns the pages at the end of the Strand Magazine with comical Zoological pictures and it could find a place under the title of "Evolution after a course of *Temperance ! Drinks !*" It is a pity that any reputable medical journal should insert such a farrago of absurdities under a scientific heading.

NOTE.—To let our readers know the nature of the philosophy of life held by the above writer, we might quote his definition of the aim of humanity. The ultimate aim of all animate beings is pleasant sensations; even the saint and the hermit seek at most an eternity of pleasant sensations. We need not go further than this loose abuse of language to show how unscientific are his terms and how puerile his treatment of the whole subject.

—:o:—

THE INJURIES OF PARTURITION, THE TIME, METHOD AND REASON FOR THEIR REPAIR*

BY A. H. TUTTLE, M.D., S. B., (Camb. Mass.)

UNLESS one is in the habit of examining the tears of parturition carefully, their extent and the possible dangers they afford or the almost impossibility—save when they are of minor degree—to satisfactorily repair them in the hurry scurry and imperfect asepsis of out-of-hospital practice can scarcely be realized, even by those who eternally urge for "immediate repair of the perineum," but forget that a primary repair of the parts requires greater skill and better surgical technique than a secondary operation and that, if the injuries are extensive, it is worse to do an imperfect operation than to leave the case alone. The pelvic cellular tissue and the region of the broad ligaments are exposed to external infection in two direct ways:—(1) A cervical tear passing beyond the cervico-vaginal junction and (2) a vaginal tear which extends from a point in the roof or side and running parallel with the urethra close to the neck of the bladder, terminates internally near the cervix. Both these tears are common and are often bilateral with one side a little greater than the other.

Unless the tears are very carefully repaired, the wound heals by secondary intention and becomes a source of great after-trouble, owing to adhesions about the ovaries and a tendency to anchor the uterus in an immovable manner and in an unnatural position.

The form of puerperal septicæmia which arises from the neglected tears should be carefully distinguished, and the fact recognised that the infection in the peritoneal space is direct and not by the way of or involving the uterus.

The perineal tears usually extend upwards through the vaginal membrane lining the lateral sulci, are rarely medial, and when bilateral, raise the corrugated membrane or raphe in the form of a thick flap with the base upwards; while the tear along the lateral sulcus often reaches to a great depth.

Most of the vesico-vaginal and vesico-urethral fistule result from forceps-extraction of an occipito-posterior presenting head or breech. The perineum is usually well torn and there is a median tear of the vagina above, involving the deeper organs and having a clean appearance as if cut by a blade of the forceps.

The skin tear of the perineum which is more or less straight, sharply defined and regular, extends in severe cases from the fourchette or hymenal ring and the mucous membrane of the rectum, but rectal tears are rarely deep, though both sphincters are at times torn and the levator ani frequently injured in all important lacerations.

Besides the above tears there are innumerable smaller ones like a crack in the tissue, short superficial and rarely severe enough to require special attention.

The mere fact of a difficult labor condemns the patient to a period of lying-in which being almost equivalent to the period of repair, is a period which in the life-time of many women is the most opportune for the treatment of her trouble, and it is a fact that in the majority of cases, convalescence would be shortened and cure hastened by complete primary repair.

If it is a simple tear a few stitches immediately placed, is all that is necessary; but when the injuries of a labor consist of more than a simple tear that does not involve the sphincter, the placenta and blood clots should be expressed from the uterus; a full dose of ergot administered, a pad wrung out in bichloride solution applied to the perineum and the patient allowed to rest for 8 to 10 hours before operation; because the repair of the cervix is easier at the end of 10 hours and the retraction of the uterus is greater at the tenth hour after parturition than in the end of the first, but a trifle more care is requisite in refreshing the parts. If the injuries have occurred early in the evening or during the night, it is wisest to wait till next day when there will be good light to work in.

Having sterilized all the necessary instruments and placed them with the antiseptic solutions, some kangaroo tendon and fine catgut sutures and an irrigator filled with bichloride solution ready to hand, the etherized patient is so placed on a table, that her parts are exposed to a good light and her back well supported. The hair about the parts are shaved, the uterus cleared of blood clots, the skin and vagina scrubbed with soap and water, and the genital canal finally irrigated with bichloride solution. The rectum is dilated and similarly cleansed. An assistant presses down on the fundus of the uterus to expose the cervix whose tears (if any), after scraping their raw surfaces with a sharp curette to insure union, are repaired by closure with an over or an interrupted suture, passed just below the mucous membrane, and exposed on the *outside* of the cervix (not inside the canal). After each stitch the blood is carefully washed away with the irrigator and the corresponding parts adjusted with the help of dissecting or (better still), PRATT'S rectal forceps.

A separate suture is used for each rent and in closing vaginal tears, carefully bring together the torn edges of the mucous membrane and muscles that correspond to each other, and unite them with sutures firmly and in close-

* Prepared by the Author at the 48th annual meeting of the American Medical Association and specially reported for the *Indian Medical Record*.

apposition so that raw surfaces are in contiguity, and their exposure along the line of tear reduced to a minimum. A suture is taken in the tears of the mucous membrane that extend up the lateral sulci, beginning at the deepest point and while the deep tears through the vault can be closed with an over stitch taken with a fine ligature, all the other rents are best treated with buried sutures. These sutures are not drawn tight until the other parts are united, because there would be less room for manipulation.

In rectal tears the first suture is taken at the external angle of the wound with very fine tendency, and the line of sutures which pass only through the muscular coat of the gut, is carried to a point just above where the skin joins the rectum and so fastened that it is entirely disconnected from the other lines of suture. The object being to prevent infection—should it occur. The deeper layers of the torn levator group of muscles and the transverse perinæi are apposed by figure of 8 sutures, and the internal and external sphincters by simple sutures. The torn edges of the perineal muscles must be brought back carefully to their normal position to ensure good fibrous union. When all the deep sutures have been placed, the ends of those closing the tears in the mucous membrane are seized and carefully drawn tight to close the wounds from infection by way of the vagina. Lastly the outer torn portions of the levator ani and transverse perinæi and the skin wounds, are repaired with two or more layers of buried sutures.

Fine buried sutures of Kangaroo tendon, passed by the help of a sound should be employed for the repair of the bladder and urethra, which should be done immediately after that of the cervix while there is yet plenty of room to work in, after the injuries are all repaired the urine is drawn, the parts irrigated, and to prevent the perineal wounds being prized open or infected by vaginal discharges, a protective suture, which may be removed in 2 or 3 days and has nothing to do directly with the closure of the perineal injury, is passed just above the lower angle of the vaginal introitus through the labia of either side, and securely tied so as to bring the surfaces of both labia into close juxtaposition, above the seat of injury.

If thorough asepsis be employed and the repairs skilfully done, healing will occur by first intention throughout with only slight fever of reaction rarely exceeding 100°F., cure rapidly results.

APPLICATION OF THE PRINCIPLE OF OSMOSIS TO THE TREATMENT OF TOXÆMIA.*

By ASSR. SURGN. WALTER MCKEOWN, B.A., M.D., M.R.C.S.E.
St. Michael's Hospital, Toronto: Canada.

UNDER the law of osmosis all crystalline bodies have the power of dialysing through an animal membrane, itself impervious to fluids, provided the opposite side of the membrane is in direct contact with a fluid of a less or greater degree of concentration.

* A preliminary report read before the Toronto Medical Society and specially condoned for favor of publication in the *Indian Medical Record*.

Specific or pathogenic organisms, once they obtained a foothold in the human body, might go on reproducing themselves indefinitely, did they not concurrently—perhaps simultaneously—form (1) a poisonous toxin and (2) an antitoxin, which more or less antidotes the former, which kills or overwhelms the vital energies of the patient.

The less toxin necessary to overcome it and the greater likelihood of the antitoxin and the normal germicidal action of the blood serum—the natural resistance of the body—bringing about a more rapid and favorable termination of the specific disease.

Toxins will dialyse, which anti-toxins will not.

Osmosis therefore offers a method of separating these bodies and leaving the antitoxins undisturbed in the circulation, while the toxins are drawn off by injecting a vein with deci-normal sodium chloride solution, to dilute the blood, and filling the rectum with saturated solution of sulphate of magnesia, which was kept in situ by a pneumatic plug carrying a large afferent and a small efferent tube provided with a stopcock. The rectal wall forms the animal membrane, and the toxins and the epsom salts the bodies capable of osmosis, while the fluids of different degrees of concentration are furnished by the blood and the sulphate of magnesia solution.

So far the theory was reasonable and plausible enough, since it indicated the mechanical application of a natural law; but it was not easy to put it into practical proof as patients were not available for a long time; but everything comes to him who waits, 'the theory' was tried with wonderful success in two cases:—The first was typhoid fever terminating in purulent peritonitis with a high temperature and small poor pulse of 150, and rendered all the more difficult and almost hopeless as the patient was almost collapsed before treatment began. The other case was that of a multipara, aged 35 years, whose lying-in was complicated by a severe attack of pneumonia which set in in a few hours of delivery and ran her temperature up to 106.4°F and her pulse rate to 180 per minute.

True successful results with two cases only, does not prove the universal efficacy of any system of therapy; but as marked improvement followed immediately upon the use of saline and magnesia sulphate, there can be no doubt in the world that the treatment and the improvement bear the relation of cause and effect.

How do pathogenic micro-organisms which do not inhabit the blood, but grow in the tissues where their toxins are produced, get into the circulation? Through the lymphatics and lymph ducts. But how do they get in there? Most probably by osmotic power which forces the toxin laden fluids onward, and the lymph channels which preserve nearly the same calibre throughout their course, further favor this as the circulation in them is more rapid than it would be, were they to widen out as do the veins.

If toxins can pass through the walls of the lymph capillaries, they will do the same through the walls of the blood capillaries and so be thrown out of the circulation together with a large quantity of the fluid constituents of the blood. That this tends to considerable concentration of the blood itself is proven by the hard, dry, brown

tongue of a patient suffering from toxæmia and to dilute the blood is to help Nature's method of getting rid of these poisons, which the solution of magnesia sulphate carries off as soon as they are thrown into the bowels and thus effectually prevents the possibility of their re-absorption.

Antitoxins on the other hand are possibly produced within the blood current and as they do not osmose or dialyse, they remain in the blood for a considerable period of time.

Whether subsequent investigation will bear out the claims and expectancies of this process or not is hard to say, but as the results so far obtained have been more than satisfactory, and as death from toxæmia is probably much more common in the specific diseases than is death from any other cause; it is not unreasonable to think that the application of the principle of osmosis offers wonderful possibilities and proves useful not only in the toxæmia due to specific disease, but also in rheumatism, uræmia, alkaloidal poisoning or any condition where the blood contains a poison, capable of dialysis through the capillary wall.

It milder cases of toxæmia where opening a vein might seem heroic, or even in the more severe when there is no immediate danger of death, the same principle of osmosis may (probably) be carried out through the skin by immersing the patient in warm water, no matter how high the temperature, because it would be more agreeable to the patient and because it would determine more blood supply to the skin and consequently hasten elimination by osmosis; but whether total immersion of the patient for a long time will drain off the toxins or not, is a question that needs close investigation.

How account for the 'chill' following saline injection? The explanation is obvious:—A condition of equalization has taken place between bodies capable of dialysis without and within the blood current. Dilution of the latter necessarily means a rapid increase from without. Hence chill; but toxins so absorbed are rapidly eliminated, and as the supply in the tissues has undergone a sudden diminution, a fall of temperature follows which continues until a new supply is elaborated.

ON VENEREAL EXCESSES AND THEIR CONSEQUENCES—GONORRHOEA OR CLAP, ITS APPEARANCE AND BEST MODE OF TREATMENT.*

By D. F. BRIGHT, M.D.

Constantinople, Bali-Pacha, Turkey.

CONSTITUTED as man is, two grand functions, viz., nutrition and reproduction, are necessary for his existence as an individual and as a species. The first of these is the general function by which the body is nourished and sustained, including in its details, digestion, absorption, circulation, respiration, secretion, excretion, etc. The second is the function by which an organised being propagates its kind, by which the continuation of our own species is kept up, and for which, great functional purposes man is accordingly furnished with organs of generation.

In the lower animals both these important functions are under the control of instinct; they have no artificial

means of rendering their food pernicious, and, therefore, do not impair their organs of nutrition. They are (in a pure state of Nature) instinctively periodical in their sexual desires, and do not, therefore, suffer from an excessive exercise of the function of reproduction.

But in man the case is different: these functions, especially that of reproduction, being (as to their exercise) under the control of the rational powers; but while he possesses the rational and moral power of understanding and guarding against excess, he, too, often violates the laws of his constitution, and seriously injures his system. By abusing his organs, and depraving his instinctive appetite, the body of man is thus made a living volcano of unclean propensities and passions, and the earth (so to speak) a mighty sepulchre for those who prematurely fall victims of the innumerable diseases resulting from the violation of the simplest laws of life, health, and happiness. Hence the importance that he should be made to understand these laws, that he may know and perform his duties consistently.

The function of nutrition and reproduction depend on the vital laws in the tissues which form the organs of the system—particularly the muscular and nervous system, but more specially the latter. The nerves of the human body are divided into two classes, viz.: The brain and spinal marrow, with their various branches and filaments; also, the faculties of sensation, perception, etc., as appertaining to animal life, are connected with the muscles of voluntary motion; and the ganglions and plexuses (of organic life) distributed to the various internal organs, and presiding over all the processes of vital chemistry; in other words, they are the immediate conductors of that vital energy by which the living body converts food into chyme, chyme into chyle, chyle into blood, and blood into the various solids and fluids of the system.

The stomach, heart, arteries, veins, lungs, liver, kidney, and all other organs concerned in nutrition (except mastication and deglutition, which are not ordinarily included), depend principally, or entirely, upon the nerves of organic life. The function of reproduction, however, depends on both sets of nerves. The power of the male organs of generation to convert a portion of the blood into semen, and to deposit this again in its appropriate receptacle, in readiness for its final expulsion, depends on the nerves of organic life; but the power to exercise the generative organs depends on the nerves of animal life. Hence, the organs of generation hold very important and intimate relations, both to the organs of nutrition, and to the brain and spinal marrow, as also to all the parts supplied by them with nervous power, and are, as it were, woven into the same grand web of organic life with the stomach, heart, lungs, etc., by being largely supplied with the same class of nerves on which the organs of nutrition depend for their functional power; but the genital organs are also supplied with nerves of animal life, or those connected with the brain and spinal marrow. Hence, the influence of the brain upon the genital organs and *vice versa*. Reciprocity exists between the organs of reproduction and nutrition. The stomach, heart, lungs, skin, etc., are immediately and strongly affected by the condition of the genitals; and these latter also participate in the affections of the former. Thus may be seen how undue

* Reproduced from *The Medical Brief* by request.

excitement is calculated to bring on and establish a state of diseased irritability and sensibility, affecting all the organs and functions, and how repetition of such excitement must necessarily induce debility and disease in the nerves of organic life, disordering and deranging the functions and often causing disorganization or actual change of structure in the brain, stomach, heart, lungs, kidneys, etc. The nerves of the genital organs are particularly liable to this general excitability, becoming exceedingly susceptible of irritation, sympathizing powerfully with all the disturbances of the system, especially, those of the brain and alimentary canal. Hence, a diseased prurience or concupiscence may be permanently established, constantly inducing excessive desires and unclean thoughts; and thus it is that individuals who were perfectly modest and consistent while in health, have become exceedingly obscene in their conduct and conversation when insane.

Such, then, are the important relations between the organs and functions of nutrition and reproduction, and the mental and moral faculties, and such their reciprocal influences upon each other that it will be easily seen how sexual desire influences the whole nervous system, and through this affects the stomach, brain, heart, and more or less all the other organs of the body. When excessive, it disorders all the functions of the system; digestion is retarded, circulation increased in the brain, stomach, lungs, and other important organs; respiration is obstructed and oppressed, and the insensible perspiration considerably diminished. Such serious disturbances cannot be often repeated or long continued without injury to the whole system. A general debility and increased irritability of the nerves of organic life is certainly produced; the energy of all the organs of the body is diminished, and their functional power consequently impaired.

The brain becomes exceedingly sensitive and the mental powers are proportionately injured, while the sympathy and reciprocity between the mental and moral faculties and the genital organs become excessive and irresistible. The nervous system is tortured into a fearful state of debility and irritability, and the vital contractility of the muscular tissues throughout the system becomes so impaired, and the muscles generally so relaxed and flaccid that all the organs and vessels of the body, even to the smallest capillaries, become enfeebled.

Through fear of contaminating the minds of youth, it has hitherto been considered the wisest plan to keep them in entire ignorance of the functions and objects of their bodily organization; and too often, in order to sustain this measure, the natural inquisitiveness of the young mind has been met by misrepresentation, and even falsehood, on the part of those who would preserve their purity, and while parents have been thus resting secure in the idea of their children's ignorance on such matters, these have been clandestinely drinking in corruption and depravity from polluted and mercenary hands. Truth, properly inculcated, can never be injurious. On this point, therefore, mankind has surely erred, both in judgment and practice. The only questions are: When and how? As to the former, I am of the opinion that it should be as early as the young mind can be made to understand the

subject. With regard to the how, I am satisfied that it should at first be as purely scientific as possible. The rudiments of anatomy and physiology should form part of the education of the youth of either sex.

This kind of knowledge can never be corrupting in its effects or tendencies, and the more scientific, the more strongly is the youthful mind secured against the evil influences of lewd associations, and it learns to think of the sexual organs with as little lasciviousness as it does of the stomach and lungs. The repeated heart-toughing, and I may truly say, heart-rending appeals which I have, from time to time, during my professional career, received from young men who have been thus left to themselves, convince me that something ought to be done for the rising generation. Incalculable good has already resulted from my single endeavors to stay the tide of debauchery which has long threatened to overwhelm the youth of this country, and, by properly directed efforts, I hope yet to be the means of saving many thousands from the calamitous evils of which I have treated in the foregoing pages. In writing as I have done, it has been with the full conviction that it may be the means of immeasurable good to my fellow creatures, and that it can not possibly be the means of evil to anyone.

It may be said, perhaps, that such a work as the present is better adapted for adults than for young boys. This is true, but I am convinced that the most important step in such a matter is in the first place to open the eyes of adults, especially of parents, guardians, teachers, and others having the care of children, from whom oral instruction adapted to the age, intelligence and circumstances of the instructed, will always be better than books in the first presentation of the subject to the youthful mind.

Woman is, by Nature, far more chaste than man; but it is possible to deprave even woman. This consideration should lead mothers to watch with great care over the physical, mental, and moral education of their daughters, for, if the vice condemned in the present chapter be practiced by them, its dreadful effects as resulting to males, are strictly true in females. Every man of correct moral discipline, must consider promiscuous and unrestrained commerce between the sexes, as equally destructive of sound morality as it is subversive of social peace and civil welfare; yet some may think that were it not for its moral, social, and civil disadvantages, such a state of unrestrained intercourse would be very desirable. Such individuals should consider, however, that even if society were destitute of all moral and civil restraint in regard to sexual commerce, yet there are fixed and permanent physiological laws which can not be violated without the inevitable penalty of the most calamitous and often loathsome diseases and suffering that human nature can endure! Many of the most terrible plagues which have, from time to time, devastated the earth, and threatened to depopulate it, have been connected with such excesses. In the proper and legitimate exercise of the genital organs, consistently with the laws of organic life, and not solely for the sensual gratification it affords, we have great enjoyment, and healthful results in the function; but when the pleasures of that function become a leading object, and the rational powers are made sub-

and the general excitement of the system, and the consequent increase of the sexual excitement, and the consequent increase of the sexual excitement, and the consequent increase of the sexual excitement.

It is not only the physical excitement between the sexes which is more injurious physically, than the excitement between husband and wife, but from the explanation previously presented, it may be readily perceived that it is not the mere loss of semen, but the peculiar and extreme excitement, quiescence of the convulsive paroxysms, etc., greatly increased by the action of the mind, which produces the mischief. Young men in the pursuit of illicit commerce with women, generally contemplate the act for a considerable time beforehand—their imagination is wrought up, and presents low, exciting images—the genital organs become stimulated, and cast their influence over the whole system. This acting on the mental and moral faculties is thence again reflected with redoubled energy upon the genital and other organs. The sight or touch of the female body greatly increases the excitement, and thus the ardour and power of the unholy passions are continually augmented, and more so in proportion to the difficulties in the way of this indulgence, the convulsive paroxysms and excitement attending which are then so violent, that they become positively hazardous to life, in proportion to their intensity. Where this promiscuous intercourse is indulged, the genital organs are almost in a constant state of stimulation and excitement. Every female a little more comely or meretricious than others in her appearance, at once becomes an object of desire to such depraved and misguided individuals; the contemplation of her charms, and even her movements, only increases the lust, and in this way are the genitals kept excited, which excitement, by a reflex action, becomes diffused over the whole nervous system, disturbing and disordering all the functions of the body, impairing the tissues, and leading to that frequency or commerce which produces the most serious consequences to the constitution. But, between the husband and wife, where there is a proper degree of chastity observed, all these causes entirely lose or are greatly diminished in their effects. They become accustomed to each other, and the intercourse between a husband and the happy, virtuous partner of his bed, is the result of the more natural instinctive excitement of the organs themselves; and when the diet and habits are such as they should be, this intercourse is comparatively seldom.

It is, therefore, may be thought of marriage as a Divine institution, authorised and enjoyed by holy writ, we may be sure that honourable marriage—the permanent and exclusive union of one man with one woman—is an institution founded on the most solid basis of things, and the most virtuous, and the most beneficial to the individual and to the community.

A HISTORY OF THE CASE

A CASE OF FATAL MALARIAL FEVER COMPLICATED WITH SEVERE CONGESTION OF THE ABDOMINAL VISCERA.

By ASSISTANT SURGEON RAJ KUMAR KUMAR, I. M. S. Surgeon: Howrah.

During the whole course of my thirty years' experience in the practice of medicine, I have never had a case like the one I am about to submit, which I attended in consultation with the veteran, Dr. HERR LAL GHOSH, who agrees with me that it was a case of intensely profound malarial toxæmia.

K. D. C. a tall, stout Hindu, 32, with a previous history of only three days fever preceded with severe shiverings, was placed on diaphoretics on the 2nd August, 1898, and after the fever 'broke' in the evening, he was given 2-grain doses of quinine six times during the night, the fever was kept in abeyance till 2 P.M. next day, when it returned and was accompanied by strong paroxysms of shivering.

On the 5th, he complained of excessive tenderness over the entire abdomen and particularly over the left lobe of the liver, and as he was passing several dysenteric stools consisting chiefly of mucus and bile, Dr. BOUQUET NATH DUTT, met me in consultation and prescribed:

R	Pulvis Ipecac	grs. iii.
	Hydrag. Gum Creta	grs. vi.
	Bismuthi subnitras	grs. 3j.
	Pulv. Gum. Tragacanth	3ss.

Misce Div. Pulvis xii. Sig. one powder every 4 hours.

The bowel disorder continued till the 7th August, when it began to abate, and on the 9th when it entirely ceased, though the tenderness over abdomen and liver, persisted; but as the patient's eyes were considerably jaundiced and his temperature refused to fall below 103°F. while the pyrexia accompanied by intense shiverings returned five times daily, and lasted from 2 to 4 hours during which the thermometer registered 106°F., Dr. HERR LAL GHOSH, was called in in consultation and we prescribed the following mixture:

R	Quinine murialis	3ss.
	Pulv. Ipecac	grs. ii.
	Bismuthi Subnit	3j.
	Tinct. Cannabæ Ind	3j.
	Spirits Æth Chlor.	3j.
	Mucilaginis Acacie	3j.
	Aquæ	ad 3vi.

Ft. Mist. Div. xii. marks.

One mark was regularly given at three-hour intervals and moderated the pyrexia a little, though it did not reduce the number of the fever paroxysms till the sixth day, when the shiverings began to gradually lessen in severity and entirely ceased in a week's time, when the fever assumed a remittent type with a morning and evening temperature, ranging from 103 to 104°F.

On the 15th August.—We found it necessary to temporarily administer the quinine in 6-grain doses three times a day, we changed the mixture to:

R	Ammon. Murialis	3j.
	Acid Nitro-mur dil	3j.
	Ext. Terebinth	3j.
	Tinct. Gentian Co.	3j.
	Spirits Chloroform	3j.
	Aquæ	ad 3vi.

Ft. Mist. Div. xii. marks, of which one mark was given

heavy forehead, but it rapidly subsided and the patient was the patient, except that on the 21st August the body was entirely covered with a reddish papillary eruption, which became great deal, and persisted for five days when it disappeared as suddenly as it had appeared.

By some inadvertence the quinine was not given on the 21st August, when the patient had these shivering fits followed by high temperature; but as soon as the quinine was resumed, the shiverings disappeared, though there was no abatement of the pain in the liver and the tongue was completely denuded of epithelium.

The tongue however remained clear, but as by the 30th August there was very little improvement in the patient, whose pulse was soft and quick and rose to 124 per minute he was given :

R Quinine mar.	3j.
Ammon. mur.	3jj.
Acid Nitro-mur Dil.	3j.
Tinct. Nucis Vom.	3ss.
Liq. Aescupul Hydrochloric	3ss.
Tinct. Gentian Co.	3iv.
Aqua	...	ad	3vi.

Ft. Mist. Div. xii marks. Sig one mark every 4 hours.

Liniment Iodi was painted over the liver and he was placed on barley, milk and broth diet, and given ℥i. of Brandy.

This brought the temperature down to 101 and 102.5°F. but did not affect the pulse-rate, and as nervous symptoms and a little delirium set in on September 5th, the Brandy was increased to ℥iii. and the mixture and dieting continued.

Two days later the patient was very low indeed; his pulse quickened to 140 and he kept picking at his nose and bed-clothes and complaining of severe abdominal pain while his bowels, which had not been moved for four days, had to be relieved by glycerine enema. Brand's essence of chicken had to be given him to maintain his strength which was rapidly failing; but on September 9th, the parotid glands of both sides swelled and became inflamed, and the patient sank lower and lower till coma supervened and he died at 3 P. M. on September 10th, which was the 41st day of his fever.

The remarkable features in this unique case were :—

- (1). Gastro-enteric symptoms from the very onset of the fever, and the persistent tenderness of the left lobe of the liver without the slightest manifestation of abscess formation.
- (2). Fever paroxysms preceded by shivering and occurring five times during each 24 hours.
- (3). Great toleration of quinine, nearly one ounce of which was given during the 41 days of illness.
- (4). The return of the shiverings and febrile paroxysms on quinine being omitted from treatment.
- (5). The peculiar reddish and very itchy eruption that suddenly appeared all over the body on August

17th, and its sudden disappearance after persisting for five days.

I would feel immensely obliged were any of our professional confreres to let me know through the medium of the *Indian Medical Record*, whether he has met a case similar to this one and how he treated it.

TREATMENT OF FILARIA MEDINENSIS IN THE HUMAN SYSTEM, BY THE HYPODERMIC INJECTION, INTO THE PARASITE ITSELF WHEN POSSIBLE OR INTO THE PART WHERE IT IS SITUATED, OF A SOLUTION OF HYDRARGYRUM PERCHLORIDE.

By E. MACKENZIE, M.D.

Manora, Karachi.

Cases arising from the presence of *Filaria Medinensis* are not common in Sind, but having been an eye witness to the suffering and inconvenience caused by it in the Dharwar and Poona districts, I have always kept in view the settling upon some better line of treatment than the stereotyped poultices and fomentations and to wait patiently for the worm to be extruded. Poultices and fomentations are very good in their way but do not cut the case short. I have tried several country remedies but with no better results. When the worm has been found superficial, good results have followed cutting upon it in its course, and holding it up over a probe, when by gentle and prolonged manipulation, with the aid of a lubricant, the worm slowly wriggles out or can be drawn out. Lately however in addition to this, when the worm has been broken and its situation is not well defined from swelling of the contiguous parts, I have injected into the swollen parts—over the site of the worm and into it when possible—a solution of Hydragr : Perchlorid grain $\frac{1}{2}$ and repeated the operation every third day three times, and have met with complete success. The swelling subsides, the pain lessens and the worm is absorbed; the opening ceases to discharge, heals up and the patient can go about his work in less than a couple of weeks. In one case where the worm had just begun to emerge from under the skin in the thigh, two hypodermic injections into the part cured the patient in less than a week and he had not to lay up at all.

The solution used is the following :—

Hydragr Perchlorid	8 grs.
Sodium Chloride	8 grs.
Glycerine	3i.
Spirit. Rectified	3i.
Distilled water added to make	of solution.

Medical Record

From October 1898.

DIRENED CITIES OF THE FUTURE. BOMBAY AND MADRAS.

II—MADRAS.

WHEN we turn to the consideration of Madras we can hardly suppress a smile. It appears from the announcement that the Government has called upon the Sanitary Commissioner for a report upon the causes of the excessively high mortality for which Madras has now unhappily become notorious.

It is just two years ago that the Government took precisely the same step: In an official memorandum dated 3rd September 1896, it requested the Sanitary Commissioner, Surgeon-Lieutenant-Colonel W. G. KING, M.B., C.M., D. P. H., to report if he could offer any explanation of the high mortality from "fevers" in Madras.

We have never heard that any action was taken on this report, nor have we any means of knowing what the Government thought of it, whether it elicited signs of approval or the reverse. On the other hand what we thought of it, is plainly set forth in the Editorial columns of our issues of the 1st and 15th February, 1898. We there showed that Dr. KING's explanation, was no explanation, and that his report from beginning to end was an incomprehensible muddle, that no one could understand it, and that no administration could act upon it.

Our criticisms appear to have been amply justified, nothing has been done, and the evil day has only been postponed. We hope that the same farce is not about to be played over again, that the report now called for will be more lucid and that some tangible results will follow. At any rate we cannot forbear a smile over the past fiasco, and the advent of the new report will be looked forward to with eagerness on our part.

Now what is the condition of affairs in Madras? We read in a communication dated the 7th September, that "the death-rate shows a considerable improvement on the late conditions, it having dropped from sixty-nine to sixty-two per mille. It is still terribly high, as the mean for the ten previous years was fifty-three."

It appears then that what may be called the normal death-rate of Madras for August stands at the appalling figure of 62 per 1000, and that recently it has gone up as high as 69.

There is no plague in Madras to account for this enormous death-rate! Madras is under its normal conditions, and presents us with an object lesson not easily forgotten, one of the largest centres of population in India, in an advanced age which boasts of its progress in everything pertaining to sanitation, with a death-rate which is little short of a scandal.

There is absolutely no reason why Madras should be unhealthy so long as its situation or climatic conditions are considered, it is the agent of the Indian Presidency, and under normal conditions its health ought to be superior to that of other cities in India.

It is a striking and curious fact that among the same sanitary error was committed in Madras as in Bombay, that is, the introduction of a large water supply before any arrangements were made for carrying it off.

It would appear as if India were in the hands of a school of sanitarians who think that sanitation begins and ends in a pipe water supply. This error, the fashionable one of the day, unfortunately appeals to everyone, to Governments, to laymen, to engineers etc., and the ease with which huge and expensive water supply schemes are passed, is little short of marvellous.

One would really think that water was the most precious fluid on the face of the earth, and that such a thing as a well must be utterly damned, while the truth is that no fluid is more easily purified and that with proper care can almost invariably be made perfectly safe.

There is a strong reaction now setting in against the long dominant theory that water is the usual vehicle by which many diseases are introduced into the system; but so powerful an ascendancy has this idea taken over many minds that we see the authorities rushing, as it were, panic stricken, in search of some distant source of water, and conveying it for miles in a complicated and expensive system of pipes, before they ever think of asking themselves how they are going to get rid of it, after it has supplied their various needs.

That an efficient drainage system should precede the introduction of a constantly flowing river of water would, one would think, be a truism that would appeal to the veriest tyro. But unfortunately such is not the case. Nor are Bombay and Madras, the only examples where the cart has been put before the horse, and the river run into the town before the drains were constructed to carry it away again.

We believe that at the present moment this same fatal course is being pursued at Karur (Coimbatore).

In our remarks on the Madras Sanitary Report for 1896, in our issue of March 1st, we pointed out that these water schemes had not been a success, and that they had not been followed by any improvement in the health of the inhabitants.

In the city of Bombay and in the town of Madras they have been accompanied by the gravest evils. The constant inflow of water added to that normally present, has been greater than the outflow, and the soil has been gradually converted into a swamp.

M. HARRIS in his paper published in one issue of the 1st October, divides the recent medical history of Madras into the antediluvian and deluvian periods, a most happy classification, and draws attention to the extreme dampness that now prevails, both in the soil and in the habitations of the less wealthy classes.

Unfortunately the topography of Madras does not readily lend itself to better drainage, so to amend or rather to modify the fears of their own predecessors the

lowing the health officer's report. We also note that the health officer, advised by the Health Officer and Assistant Health Officer, all these are no doubt excellent ways of setting one's house in order, and preparing for the struggle with a destructive epidemic.

Under the heading of Litigation we learn that "these were rather numerous over last year in the total number of prosecutions. The fines, however, were altogether inadequate and non-deterrent in their effect."

"Year after year it has been noted that the punishments imposed by Honorary Magistrates are ineffective, and in many instances tend to offer a direct premium for the infringement of Municipal law." Thus the average fine for "building houses without sanction" was only Rs. 1-6, for "stopping drains contrary to orders" Rs. 4-8-6 and for depositing offensive matter on public streets, Rs. 1-2.

Under the Vaccination Act, in the Town proper and the amalgamated area, there were 871 prosecutions against 768 in the previous year, and the amount of the fines was Rs. 182. The prosecutions were (1) for not vaccinating children after notice, and (2) for not bringing children for inspection after vaccination.

We will be curious to see what will be the fate of the vaccination laws in this country. We fancy that the anti-vaccinationists in England will not be satisfied with their victory there, but will use their best endeavours to extend its sway to the Indian Empire. If this unfortunate result is attained, small-pox, which at present is on the decline, and appears to have been brought fairly under control, may be expected to increase by leaps and bounds.

Calcutta is provided with a double water supply, one filtered the other unfiltered, extensions made to the pipes for filtered water amounted to 256 miles during the year; the total length is now 314 62 miles.

In addition to petty pipe extensions 15 62 miles were added to the unfiltered water pipes.

The consumption of filtered water was less, and of unfiltered water more than during the previous year.

The consumption of filtered water per head per day is estimated at 88 10 gallons in the town and 11 26 gallons in the suburbs, and of unfiltered water 12 51 gallons.

The brick sewers suffered from the earthquake, the one most affected being the main outfall sewer between Circular Road and Palmer's Bridge silt-pits. It was found necessary to put in 663 lineal feet of strong tie rods and to wedge all the cracks, altogether 1 12 miles has to be repaired.

The sewerage was further improved by the construction of a number of gully-pits, man-holes, flushing chambers, etc., and the construction of new model latrines and urinals.

The long mooted question of the drainage of Fort William is still in statu quo. We learn that, "in June 1897, the Executive Engineer, Fort William, forwarded a project for the establishment of a pail-depot in Olive's Bazaar, to be supplied by a pipe with the municipal water in the Esplanade Road. This project was approved by the Engineers of the Corporation. In March 1898, the Municipal Council passed a resolution that the pail-depot should be established at the Esplanade, at a cost of Rs. 2,000 a year

for the use of the city and, this, however, was the same as the year the Government of India had issued for information regarding the change in the water supply, and the advantage of the proposed sewerage system over the present plan of discharging by cart into the Calcutta drains on the Budge-Budge Road."

This looks as if the Fort were to enjoy for a few more years, the odours for which it is notorious, and which at times makes some of its gates almost impassable.

Considerable progress was made with the New Drainage Works which include a scheme for the disposal of storm water and sewage outfall of the town area, and suburban drainage north of Tolly's Nallah. The work of pipe-laying under the nallah was begun in October 1897. The canal authorities sanctioned the closure of the nallah to keep out the tidal water, and the work was progressing rapidly when a difficulty arose in supplying water to the Docks, the dam had to be cut and the work postponed.

Considerable difficulty was also experienced in laying the Ballygunge main sewer on account of quicksands which greatly retard the progress of the work.

The quantity of sewage lifted at the Drainage Pumping Station at Palmer's Bridge reached the enormous average of 18,087,898 gallons daily against 17,627,801 for the previous year.

14,276,250 cubic feet of rubbish were deposited during the year in the Salt Lakes, chiefly in the Southern area of the square mile against 13,824,000 in the previous year.

HEALTH OF CALCUTTA. VITAL STATISTICS.

The birth-rate for 1897 was 18 4 exactly the same as for the year 1896, that is higher than it was in five out of the previous eight years.

The death-rate was 36 1 or higher than any year in the previous eight with the exception of 1895 when, according to the Health Officer's report, it was 39 6.

These figures compare very badly with what prevails in England and Wales, where the birth-rate averages about 30, and the death-rate under 20 per 1,000.

For the year 1895, Madras town recorded a birth-rate of 42 5 and a death-rate of 38, and Bombay City a birth-rate of 19 35 and a death-rate of 40 90. The mean death-rate in Bombay for five years was 30 77.

In Calcutta the birth-rate was as usual highest amongst Christians and "other classes" and higher amongst Hindoos than Mahomedans.

There were 79 still-births to every 100 live-births.

A decline in the public health of Calcutta was noticed in the reports of 1895 and 1896. A similar decline is noticeable in 1897, this decline was greater in the suburban area than in the old town area, and in the area bordering on the circular canal than in the rest of the suburbs.

Under "mortality according to age" we learn that out of the 24,865 deaths that took place during the year, no less than 6,817 or more than a fourth part occurred under five years; again, "while the death-rate per 1,000 between 5 and 60 years is not excessive for an oriental city, that between the ages of one and five years is at least five or six times what it should be in a healthy town, while under one year it amounts to 255 5 per 1,000 which is proportionately as excessive."

This high infant mortality derives special significance from the fact that it has been steadily increasing since 1892. "The alarming state of things disclosed by these statistics," we read, "calls for speedy attention from the sanitary authority of the city." In his report for the year 1895, the late Health Officer, Dr. SIMMONS, drew attention to this insidious aspect of Calcutta in the following words :—

The high mortality among infants is a prominent and discreditable feature of Calcutta, and urgently calls for improved sanitation in connection with the construction and cleanliness of dwellings and the proper regulation of the milk-supply, in addition to an improvement of the general drainage and cleanliness of the town. Though a good deal of any improvement in the health of the infant population will, in the long run, depend on the spread of sanitary education among the masses and particularly among the female section of the community, a considerable part of it lies within the range of public hygiene ; and this particularly applies to the laying down of proper rules and regulations for the construction of sanitary dwellings and for the control of the milk-supply of Calcutta, to the removal of the defects in the general drainage, and to the adoption of proper means to secure an efficient daily cleansing of the town."

In the present report the Health Officer draws attention to the necessity of "setting apart of suitable localities for cow-houses in sparsely populated parts of the town, the construction or remodelling of all cow-houses and dairies on approved sanitary patterns, and the abolition of the sale of milk or its products by itinerant vendors having no fixed dairies or shops in Calcutta."

Regarding the causes of the high mortality recorded, it appears that compared with the mean of the preceding eight years there has been a rise in the mortality from all causes, with the exception of small-pox.

There were 161 deaths from small-pox during the year against a mean of 467

This unfortunately is no proof of the general diminution of the disease, for in only three of the previous eight years was the mortality higher, and owing to sudden and intense epidemics large fluctuations occur. Thus in 1895, 2,220 deaths were recorded, followed by 69 deaths in the succeeding year.

Again while the increased mortality from the other groups into which diseases are classified, is a formidable indictment of the sanitation of Calcutta, no comfort can be extracted from the lessened number of deaths from small-pox.

THE OUTBREAK OF TYPHOID FEVER AT MAIDSTONE.

We are indebted to the "Public Health Engineer" for the detailed report on the Maidstone Typhoid Epidemic which has been issued in the form of a Parliamentary paper by the Local Government Board.

We take the following extracts from the "conclusions" arrived at :—

"On a review of the whole of the evidence, we have no hesitation in coming to the conclusion that the epidemic was caused by the pollution of the water supplied by the Maidstone Company from their Farleigh sources.

It is true that there is abundant testimony to show that grave sanitary defects exist in the construction of some of the sewers, and of many house drains and waterclosets within the borough ; while one of the expert witnesses, Dr. CORFIELD, said that, in his opinion, these defects were sufficient to account for the epidemic. But the sudden and simultaneous outbreak of fever over a wide area, and the rapidity with which the epidemic grew, cannot be accounted for by the existence of defective conditions of sewerage and drainage. Further, the facts as to the local incidence of the disease, which have already been stated, are not consistent with the theory that these conditions had anything to do with its origin. The old brick barrel sewers are almost all in the lower part of the town, which was comparatively free from attack, especially at the commencement of the epidemic ; and the hand-flushed closets and defective house drains are distributed pretty equally over the whole town, whereas the cases of typhoid fever were confined to the Farleigh area of water supply to an extent which quite precludes the possibility of mere chance."

"It was objected that the evidence, strongly as it points to the pollution of the Farleigh supply, was circumstantial, and established grounds of suspicion only. But it was supplemented by other facts, which appear to us to leave no room for doubt. The chemical analyses of samples of water taken from some of the springs after the epidemic broke out, show that the Farleigh supply had been dangerously polluted ; and the bacteriological examination of the samples from two at least of the springs afforded conclusive evidence of excremental pollution by man or the lower animals. Dr. SIMS WOODHEAD, indeed, contended that his examination did not definitely prove that this was the case, and that the colonies which he found were merely indicative of what he called "surface relations." It would be beyond our province to discuss the difference of opinion between "Dr. SIMS WOODHEAD and the other experts who were examined as to the exact significance of the discovery of the *Bacillus Coli* in water, or as to the proper classification of bacteria of this species ; but it may be pointed out that "relations" between water supplies and the "surface" of gardens and fields like those which surround the Farleigh sources must be extremely dangerous. And in this case the evidence shows clearly that the neighbourhood of some of the springs was immediately before the outbreak, plentifully covered with human excrement. It is moreover, to be borne in mind that Dr. WOODHEAD's samples were taken some time after the water had been examined by Dr. WASHBURN, and that consequently the condition of the water may have altered considerably. The testimony of the scientific witnesses at the inquiry was to the effect that the *Bacillus Typhosus* is seldom or never recognized in water, so that the fact that it was not discovered in this case is not remarkable, even if no allowance be made for the time which had elapsed between the introduction of the poison into the springs and the examination of the water. With reference to the fact that there was no history of any recognized case of typhoid fever in the neighbourhood of the Farleigh springs before the epidemic, it may be remarked that cases of typhoid fever are not always recognized and notified."
